Royal Horticultural Society's Journal.—The current issue (Vol. XXXIX., Part 2) of this publication is of quite exceptional interest to those who devote special attention to hardy flowers, and has much value for purposes of reference in connection with rose literature and primulas. It contains a report of the Primula Conference, held under the presidency of Sir J. T. D. Llewelyn, Bart., at the Horticultural Hall on April 16 last. The text is given of the whole of the papers which were read by Dr. John MacWatt, Mr. Reginald Farrar, Professor I. Bayley Balfour, F.R.S., V.M.H., Mr. W. G. Craib, M.A., and Miss Jekyll. The comprehensive paper on "Indian Primulas" by Sir George Watt, C.I.G., has been reproduced from an earlier issue of the "Journal." There is also a list of European species of primula, with synonymy, based upon the arrangement of Pax's monograph in Engler's "Pflanzenreich," and the hope is expressed that it will prove useful to cultivators. The report is accompanied by seventy-nine photographic reproductions illustrative of the more important of the species, both new and old. Especially deserving of attention among the papers, other than those concerned with primulas, are Mr. Arthur Paul's important and entertaining "Literature of the Rose," Mr. W. H. Diver's instructive paper on "The Spring Flower Garden," and the Rev. Professor G. Henslow's carefully-considered paper on "The Origin of Life," which, he states, is, in his opinion, undiscoverable.

The Merite Agricole.—By decree signed by the Minister of Agriculture, and recently published in the "Journal Officiel," some alterations in the constitution of this order have been made, as recommended by the French Senate. The Council is composed of the Minister of Agriculture as president, together with a number of colleagues holding the highest positions in the agricultural community in France. The decoration is conferred not only upon agriculturists, but also upon eminent horticulturists, horticulture in France being regarded for this purpose as a branch of agriculture. To be entitled to the decoration in any grade, Chevalier, Officer, or Commander, the candidate must have ten years' genuine service to his credit. The decree limits the total number of recipients in each grade that are to be annually appointed.

Horticultural Instruction in Staffordshire. — Horticultural instruction has a prominent place in the directory for higher education which has been issued by the Education Committee of the Staffordshire County Council. The horticultural instructors for the county are Mr. J. Stoney and Mr. G. W. Pyman, and their activities include lectures on the cultivation of plants, flowers, and vegetables during the winter months, which for the most part are illustrated by lantern slides; and lectures and open-air demonstrations during the spring and summer months.

A New Grass Parasite (Cladochytrium graminis) is described by Mr. George Massee, V.M.H., in the current issue of the Kew Bulletin (No. 6, 1913), and the disease caused by the fungus may, unless due care is observed in the selection of seed, cause considerable trouble. The parasite was first observed in this country in 1908, when a sod of diseased grass was sent to Kew. In connection with this it was stated that the disease had appeared in every instance where portions of a consignment of Continental grass seed had been sown. The spread of the disease was checked by the removal and burning of all diseased patches, and nothing more had been heard of the parasite until the present season, when its presence was notified at Kew from several widely-separated localities in the South of England. At present the parasite has only been observed to attack species of festuca, and other grasses with small leaves, and is, consequently, most prevalent on lawns, tennis grounds, and bowling greens. The symptoms of its presence are the appearance of small yellowish patches, a few inches across, scattered over the lawn. These patches gradually increase in size, and often encroach on each other, forming large irregularly-shaped areas, which eventually become brown owing to the entire disappearance of the grass. This fungus is described by Mr. Massee as belonging to a primitive type, in which the reproductive bodies, called zoospores, possess the power of spontaneous movement in a film of water, by which they are enabled to migrate from their place of origin and infect adjacent plants. Mr. Massee found by watering the diseased grass with a solution of sulphate of iron, prepared by adding half a pound to a gallon of water, the spread of the disease is checked, and he emphasises the fact that it is important the treatment should be repeated two or three times, at intervals of ten days, as free zoospores only are killed, and these are liberated at intervals. In Mr. Massee's opinion, the most certain method for preventing the wholesale spread of the disease turns on the selection of seed from districts free therefrom, and this he considers should prove a comparatively easy matter.

Hardy Flowers at Greenwich Park.—Mr. T. Hay, the superintendent of this beautiful park, is repeating some of the successes he achieved in the Hopetoun House gardens, but on an even more extensive scale, and the attractions of the park have been enormously enhanced as the result thereof. A correspondent, who highly appreciates the distinctive charm and interest of hardy perennials, writes with reference to Mr. Hay's achievements: "A perfect object-lesson in the use and value of hardy perennials may now be seen in Greenwich Park for the third year in succession. In its initial stages the venture met with doubt and criticism. Long custom dies hard, as may naturally be expected in the case of those whose years are spent in the patient watching of seed and plant growth. We are all more or less creatures of circumstance. Although the victory may be said to have been won last year, when hardy plants quite came into their own, the effect this year on a largely-increased scale is more striking and convincing than ever. A huge border from a hundred and fifty to two hundred yards in length, and from ten to twenty feet wide, presents wonderful results in herbaceous gardening. It is worth a long journey to see such a massive colour scheme. If such a demonstration was necessary to prove the greater utility and beauty of hardy plants, then this bold conception has done something for the gardening world. It will be at once conceded that this style of gardening eminently accords with the bold dignity of a great park, and yet is capable of adoption on a small scale."

School Gardening.—The interest in school gardening in this country continues to increase, as proved by the fact that 50,000 children, of whom 2,000 are girls, in the elementary schools, are receiving instruction in the elements of the gardening art by means of school gardens.

Station Gardens on the Glasgow and South-Western Railway.—The directors of the Glasgow and South-Western Railway annually offer prizes for the best-kept station gardens on the system. Many of the gardens have been very fine this season, despite the dry weather, and our correspondent was much struck with their beauty. The following are the principal awards: First Class, £5 each.—Mr. James Candlish, Southwick; Mr. W. Taylor, Dalmellington; Mr. A. Morren, Annbank; Mr. W. B. Kirkpatrick, Dalbeattie; Mr. J. Rae, Carronbridge; Mr. G. Paterson, Glenside; Mr. G. Macdonald, Moniaive; Mr. R. Fisher, Dalrymple; Mr. T. Gillies, Alloway; Mr. James Barr, Ruthwell; Mr. W. R. Beckett, Dunure; and Mr. J. Mirrey, Lochanhead. Second Class, £4 each.—Mr. E. Blackwood, Mountgreenan; Mr. J. Houston, Closeburn; Mr. J. Reid, Sanquhar; Mr. J. S. Faulds, Maxwelltown; Mr. W. Chalmers, Kilkerran; Mr. J. Taylor, Maidens; Mr. J. Hamilton, Cunninghamhead; Mr. P. Lawson, Rankinston; Mr. G. Hay, Paisley West; and Mr. T. Murray, Howwood.

GLASGOW FLOWER SHOW,

SEPTEMBER 3 and 4.

The exhibition held by the Glasgow and West of Scotland Horticultural Society on September 3 and 4, was one of the few shows of which it may justly be said that this year's was better than usual. It is true that here, as elsewhere, some of the classes had not what may be called their full complement of entries, owing, of course, to the trying weather conditions, but quality was distinctly good, and the chief improvement was in the arrangement of the exhibits. The society changed their venue to the Zoo Buildings, a spacious, well-lit, and well-ventilated hall, where ample room could be provided alike for exhibits and spectators, and everything could be well seen, thanks to the capital light from a clear lantern roof.

PLANTS.

Mr. Adam Knight, gardener to Sir Wilfred Lawson, Bart., Brayton Hall, Carlisle, was the winner of first prize for a group of miscellaneous plants, occupying a circle of 9ft. in diameter. His arrangement was light and artistic, good use being made of pink and white spiræas, good sprays of oncidiums, and some salmon and rose-shaded clarkias. Lilium speciosum and a plant or two of malmaison carnations were also used, with a suitable variety of crotons and other foliage plants to break up the floral work. Mr. A. Kelly, gardener to Wm. Beattie, Esq., Dinwidding, Milnegavil, took second prize, arranging his group in a pyramidal mound with Lilium longiflorum, celosias, and caladiums supporting the central part of Phœnix Roebelini. A number of acalyphas were used as dot plants with good effect.

Mr. James Templeton, gardener to Mrs. Alexander Rose, Richmond House, Dowanhill, took first prize for three palms, showing a very good Phœnix rupicola, Areca lutescens, and Kentia Belmoriana. The best two greenhouse plants were shown by Mr. Thos. Nelson, Muirbank, Rutherglen, a well-flowered statice and a Dracæna australis variegata being his choice. Mr. Jas. Jamie, 3, Fotheringham Road, Ayr, had a red bouvardia and a white lapageria as his second prize plants. Three stove or greenhouse plants secured first prize for Mr. Adam Knight, who showed an oncidium, a croton, and Vallota purpurea; second prize went to Mr. Alex. L. Davidson, gardener to Sir Andrew H. Pettigrew, Baronald, Lanark; and third to Mr. John O'Neil, gardener to Mrs. Murray, Rosebank, Partick, Glasgow. Mr. John Davidson, gardener to John Reid, Esq., Ardencraig, Rothesay, showed three beautiful dracænas for first prize, a capital plant of D. atropurpurea being included in the set.

Six ferns for table decoration brought some very nice things. Mr. Thos. Nelson, Rutherglen, leading with Nephrolepis Marshalli, Gymnogramma Mertensi, and G. superba in his half-dozen. Mr. Nelson also took leading honours for three large British ferns, showing vigorous plants of Polystichium vulgare, Scolopendrium vulgare crispum, and an athyrium of pleasing character. Second prize was secured by Mr. Chas. Pattison, Paisley, whose Polypodium cambricum carried fine fronds.

Dwarf British ferns were nicely shown, Mr. Chas. Pattison, Bridge Street, Linwood, Paisley, obtaining first prize for a capital set. Asplenium trichomanes incisum was beautifully grown, and Blechnum spicant ramo-cristatum was particularly well crested and fringed. Mr. Thos. Nelson, Muirbank, Rutherglen, took second prize, showing Polystichium plumosum densum, and one or two very fine scolopendriums. Mr. Chas. McIver, gardener to T. Clement, Esq., Barcapel, Newton Mearns, came a good third. For Adiantum pedatum being very nice. For six nephrolepis first prizewinner was Mr. Jas. Thompson, Broomfield, Giffnock, his varieties being some of the latest developments, represented by well-grown plants. Three large specimen exotic ferns were shown by Mr. Alex. L. Davidson, and worthily awarded first prize. Nephrolepis todeaoides, N. exaltata Piersoni, and Adiantum cuneatum were the kinds shown. The beautiful moss-like Nephrolepis Rochfordi was included in Mr. Thos. Nelson's second-prize lot. A splendidly grown aspidistra brought first prize to Miss M. A. McCombie, St. Vincent Crescent, Glasgow, in the class for a plant grown in a dwelling house. Mr. G. R. McCallum, Regent Street, Shawlands, took second prize with a nice healthy Araucaria excelsa. Miss McCombie again beat Mr. McCallum for three house-grown plants.

Two capital pyramid fuchsias, well flowered from top to base, were given first prize, they being shown by Mr. Jas. Swan, Railway Buildings, Lennoxtown; Mr. Walter Rae, Woodville, Biggar, taking second prize. The winner for a single specimen fuchsia was Mr. Jas. Jamie, Mr. Swan in this case being second. Two good pots of Lilium speciosum vars. album and Melpomene were shown by Mr. Thos. Nelson, bringing him first prize. Mrs. Thos. Carlyle, Lilium Cottage, Maryhill, scored for a pot of Lilium auratum.

CUT FLOWERS.

Gladioli are regularly a great feature at Glasgow Show, and, although this year the drought had its effect on the number of entries, there were still some wonderful spikes of flowers shown. Messrs. Alex. E. Campbell and Son, Cove Gardens, Gourock, received first prize for twenty-four spikes. They were of great length, and carried as many as ten and twelve open bells per spike. Charles Bertier, a rosy-lilac with white throat; Bernina, a white, and Fournaise, scarlet, were three extremely good varieties.

Messrs. G. Mair and Son, Prestwick, were second prize winners, their exhibit containing some grand even spikes. Mr. James Stewart, jun., Woodend Cottage, Whins, Alloa, was first in the amateurs' class for six gladioli. He had Etincelle in nice form, Aristophane being a variety of charming salmon-rose colour, with yellow blotch. Mr. Thos. Nelson won second prize, Mr. R. S. Aitkenhead, Larkfield, Gourock, being third.

Twelve bunches of hardy herbaceous flowers made an excellent and pleasing class. First prize was placed to the credit of Mr. Chas. Pattison, Bridge Street, Linwood, Paisley, Scabiosa caucasica, Eucomis punctata, Lathyrus latifolius albus, and Chelone barbatus coccinea being beautiful bunches. Coreopsis grandiflora Meiklemi was well shown. It is broader in petal and more striking than ordinary forms of this useful plant. Mr. Robert McLelland was second, showing some very useful things. Artimisia lactiflora, Delphinium Mrs. Creighton, and Lobelia cardinalis were choice. The third prize lot came from Mr. Peter Anderson, gardener to W. Fleming, Esq., Park Inchinnan, Renfrew. Twelve bunches of hardy flowers, shown by Mr. Chas. Pattison, won first prize. Among the subjects staged were Montbretia Germania, Phlox Sheriff Ivory, and a good variety of Chrysanthemum maximum. Mr. Robert McLelland, gardener to Alex. Murray, Esq., Duncryne-by-Alexandria, was second.

Mr. Charles Pattison's first prize exhibit of six bunches of hardy border flowers were a very good lot. Sidalcea Rosy Gem, Artemisia lactiflora, Montbretia crocosmæflora, Helenium pumilum magnificum, Veronica longifolia subsessilis, and Lilium tigrinum splendens were all good bunches.

ROSES.

Some first-class roses were staged, and considerable enthusiasm was evidenced by the visitors, who pressed round the winning stands. Messrs. Hugh Dickson, Lim., Belfast, won the leading prize for thirty-six blooms. Their stand contained chiefly varieties introduced within the past few years, and it was interesting to note that in Ireland, anyway, good autumn roses are to be found in David Gilmore, Archie Gray, Triumph, and Mrs. Theodore Rooseveldt. One or two old favourites were Ulrich Brunner, Mrs. J. Laing, and Alfred Colomb. Second prize was awarded Mr. W. Ferguson, Dunfermline, whose flowers were fresh, and, for the most part, of good substance. Mr. R. G. Ferguson, South Nurseries, Dunfermline, came in third, the flowers lacking somewhat in size and substance.

The amateurs' class for twenty-four roses had but one entrant, the exhibitor being Mr. G. A. Turnbull, Gaselock, Helensburgh, who was awarded first prize. For twelve blooms Mr. Frank Watt, Firbank, Kilbirnie, was first with some very good blooms. Mr. R. S. Aitkenhead, Larkfield, Gourock, took second prize. Mr. Robert Barrowman, Rosebank, Bargeddie, taking the remaining prize. Messrs. Hugh Dickson, Lim., staged beautifully in the class for eight vases of decorative roses, their white variety, Simplicity, the brilliant Muriel Dickson, and velvety H. E. Richardson, with Golden Gem, being some lovely roses. Second prize went to Mr. W. Ferguson, Dunfermline, and third to Mr. R. C. Ferguson. Mr. W. Ferguson scored for six vases of five blooms each, Mr. R. C. Ferguson following. Vase classes for amateurs filled well, some of the single vases of certain colours producing very good blooms.

SWEET PEAS

made a big and, for so late in the season, a very noteworthy display. The quality from one end to the other was very good, some of the larger classes containing entries well above average exhibition quality. Mr. John Smellie, Pansy Gardens, Busby, put up a very pleasing stand of twelve vases, receiving first prize. Rosabelle, Lavender George Herbert, Hercules, R. F. Felton, King Manoel, Hilda, May Campbell, Dorothy, Scarlet Emperor, Barbara, Agricola, and Edrom Beauty were the varieties staged. Second prize was won by Mr. J. H. Crosby, The Ross, Comrie, whose flowers lacked a trifle of the freshness and size of the winners, but were still good. Mr. George Bowness, Riverside Nursery, Busby, was third with well-grown flowers, just here and there a bit weather worn.

The proprietors of the "Glasgow Evening Citizen" provided prizes for another class of twelve vases of sweet peas, to be selected from a list of varieties named in the schedule. First prize in this class went to Mr. J. H. Crosby, The Ross, Comrie. He had good flowers on capital stems, but could, we thought, have staged less stiffly, with better effect. Mr. George Bowness, Busby, received second prize with a very showy lot, and even the third prize set, put up by Mr. J. Smellie, was very little behind the first in quality. A very big class was that for nine bunches of sweet peas, the exhibits extending half the length of the hall. Mr. J. R. Paterson, Beild Farm, Gargunnock, led the way over quite an army of competitors.

Mr. J. Smellie, Busby, scored a good win for twelve bunches of early-flowering chrysanthemums, Abercorn Beauty, Busby Yellow, and Crimson Polly being three bright,

good varieties on the stand. Mr. Geo. Bowness, Busby, was given second prize. For six vases Mr. Robert Sutherland was the winner. He showed good bunches of useful sorts. Mr. W. P. Blyth, 11, Queen's Gate, Clarkston, claimed second prize, the third going to Mr. Geo. Robertson, Eastwood, Thornliebank. Mr. Thos. Nelson secured first prize for three bunches, showing Crimson Polly, Mina Blick, and White Masse.

DAHLIAS, CARNATIONS, AND VIOLAS.

Mr. J. Smellie, Busby, had some good blooms on his first-prize stand of twenty-four show and fancy dahlias. Such old favourites as Mrs. Saunders, Shottesham Hero, A. V. Rawlings, and Colonist were represented. Second prize was won by Messrs. Bannatyne and Jackson, Hamilton. Mr. David Barbour, Johnshill, Lochwinnoch, led with twelve blooms, followed by Mr. Wm. Jenkins, Lightburn Road, Cambuslang, and Mr. Robert Sutherland, Auld Isle, Kirkintilloch. Twenty-four cactus dahlias on boards brought another first prize to the credit of Mr. John Smellie, his stand containing capital flowers of modern varieties. Mr. Geo. Bowness, Busby, came just behind the winner, and was in turn followed by Mr. J. Sutherland, Victoria Nursery, Lenzie. Mr. Smellie led again for twelve vases of pompon dahlias, the winner for six vases being Mr. Jas. Paul, Drumbeg, Killearn, who also won first for three vases.

Mr. Jas. Nichol, gardener to Allan Kirkwood, Esq., Darnley, Nitshill, staged the winning twelve vases of border carnations, showing, among other varieties, Gertie, Lord Steyne, Alfonso, and Gretchen. The same exhibitor had the best three vases, being followed by Mr. Peter Anderson, Inchinnan, Renfrew, and Mr. Jas. Frew, Darnley, Nitshill. Forty-eight violas, shown on boards, was a class after the heart of the old florists, a few of whom yet remain to discuss with animation the points and merits of their favourite flowers. Mr. Alex. McAlpine, Viola Gardens, Cleland, took the leading prize, his flowers being large, smooth, clear in colour, and symmetrical in outline. Second prize was taken by Mr. Jas. McKellop, Craigbinning, Upshall, whose flowers just lacked the smoothness and evenness that is aimed at. Third prize went to Mr. John Johnstone, Law.

FRUIT

was remarkably fine, especially the grapes, competition throughout the extended classification being very keen. The opening class was for twelve dishes of fruit, Mr. Jas. Brown, gardener to A. A. Hagart Speirs, Esq., Houston, taking premier honours. Black and white grapes, Crimson Galande and Royal George peaches, and fine pears, apples, nectarines, and melons were beautiful produce. We could find no second award in this class. The winner for six dishes was Mr. D. McIntosh, gardener to E. Bewley, Esq., Danum, Rathgar, Dublin. His Peasgood apples were wonderful for size and colour, and his other dishes were also good. Second prize in this class went to Mr. Hugh MacSkimming, gardener to W. T. Machellan, Esq., Auchenault, Helensburgh; and third prize was awarded Mr. John Finnie, Summerhill, Shandon.

Eight bunches of grapes, to include no more than two of one variety, was the principal class, and the quality was splendid. First prize went to Mr. Robert Glen, gardener to R. M. Donaldson, Esq., Blairvaddick Row, Helensburgh. His bunches were Appley Towers, Muscat of Alexandria, Madresfield Court, and Black Hamburgh. The finish, as well as size of berry and build of bunch, was good all through. Mr. David Halliday, gardener to W. Mackay, Esq., Ascog, Rothesay, was close up for second place. Mrs. Pince was a huge bunch, Alicante had great merit for size, and carried beautiful bloom, Madresfield Court and Muscat of Alexandria were other varieties shown, and also Black Hamburgh. Mr. John Middleton, gardener to Wm. Forbes, Esq., Callendar House, Falkirk, took third prize. He had two bunches of Mrs. Pearson, Muscat Hamburgh, Black Hamburgh, Appley Towers, and Muscat of Alexandria, a set that showed skilful handling, but one or two bunches would have hung another week with advantage.

Mr. Hugh MacSkimming won first prize for four bunches of grapes, showing rich-coloured Muscats and heavy bunches of Black Hamburgh. The second prize went to Mr. John Finnie, who also had good colour in his white grapes, beating Mr. David Halliday, who took third place. Mr. MacSkimming took the lead for two bunches of white Muscats, beating Mr. John Finnie and Mr. D. McIntosh, Dublin. Again for two bunches of Black Hamburgh Mr. MacSkimming scored, second prize going to Mr. John Middleton, Mr. Robert Glen coming third. The best two bunches of Alicante were put up by Mr. David Halliday, the bunches being very weighty and carrying good bloom.

Mr. McIntosh, Dublin, had some grand apples in the class for twenty-four, in six varieties. First prize was easily won. Emperor Alexander, Rival, and Cox's Pomona were very fine indeed. Mr. Thomas Smith, Dundonald Road, Kilmarnock, had nice apples in his second prize exhibit, but they were practically green in comparison with the winner's. For a collection of pears the lead was taken by Mr. Andrew Harvey, gardener to Miss Hamilton, Rozelle, Ayr. He had Marguerite Marillat splendidly developed and coloured, and Beurre Hardy was also fine. Mr. McIntosh took second prize in this class.

VEGETABLES.

There were a number of collections of vegetables which possessed capital quality. Scottish growers are always keen on their vegetables for show, and we are never disappointed in our expectations of finding something really good. One class, for thirteen dishes, was contested only by two exhibitors, but the vegetables staged by them were of high quality. Mr. Charles Shaw, gardener to S. Mitchell, Esq., Boquhan, Kippen, was adjudged victor, and certainly he had the better of his opponent in onions, parsnips, yellow turnips, beetroot, and peas, but other dishes were very closely matched, and it was not just a walkover. Mr. William Bell, gardener to the Right Hon. Earl of Home, Bothwell Castle, received second prize.

In another class which was for nine dishes Mr. James Brown, Houston, came first. His produce was even and shapely, the parsnips and carrots being of good size. Mr. Charles Shaw took second prize in this class, the produce not being up to the standard of his bigger collection, but he had some capital potatoes and peas; Mr. John Gray, Middlewood, Uddingston, was placed third. In a second class for thirteen dishes, Mr. Charles Shaw was again first, with Mr. W. P. Bell once more closely following. Both exhibits were very creditable to the exhibitors, who know not only how to grow, but how to properly show vegetables.

In another nine-dish class, with a silver cup offered as the first prize, Mr. John Gray, Middlewood, Uddingston, was the fortunate winner. His leeks and Prolific potatoes were fine, and parsnips, too, were very long, even, and smooth. Second prize here went to Mr. Joseph Devoy, 30, Dalrymple Street, Stranraer, Mr. George Watson, Kirkhill, Kippenby-Stirling, taking the remaining prize. Messrs. Forrest and Co., Welldale Nurseries, Douglas, Lanarkshire, had a most remarkable collection of tomatoes, which were arranged in mounds and pyramids in a very effective manner. There were probably twenty or more varieties, and first prize was awarded them, second prize going to Mr. John Hood, Dalmore, Helensburgh.

NON-COMPETITIVE EXHIBITS.

These were numerous, extensive, and excellent. In fact, they would have made a good show in themselves. Messrs. Sutton and Sons, Reading, had one of their large decorative stands of choice vegetables, including a number of novelties that attracted a good deal of attention. The floral decorations were charming, the new red Sunflower being conspicuous. Messrs. Sander and Sons, St. Albans, brought up a choice little batch of orchids that were representative of some uncommon tribes, as well as the more familiar. Mr. D. G. Purdie, 6, Waterloo Street, Glasgow, showed a miscellaneous group of ferns and foliage plants with groups of begonias, liliums, and hydrangeas interspersed.

A great bank of collarette dahlias, with some good garden roses, and a host of sweet peas, came from Messrs. Dobbie and Co., Edinburgh. In each section the varieties were as good as could be obtained from any source at this season. The Killermont Nursery Company, Bearsden, Dumbartonshire, staged a good display of border carnations, together with a few roses, the whole being set up with an airy lightness that showed the flowers to advantage. Hardy flowers, including some very choice things, were shown by Messrs. Cunningham, Fraser, and Co., Comely Bank Nurseries, Edinburgh, and Messrs. Guthrie Bros., Priory Nursery, Ladybank, also showed hardy flowers with roses and sweet peas. Messrs. Bannatyne and Jackson, Hamilton, made a fine show of cactus, show, and pompon dahlias; and Mr. Arthur Brown, Blantyre, also showed dahlias beside a selection of pansies, violas, and early chrysanthemums. Mr. John Hood, Kerse Nursery, Kilbirnie, had some very good pansies, and a new tomato called Hood's Hero. Messrs. Pringle and Alexander, 17, Waterloo Street, Glasgow, showed samples of apples, vegetables, and a few roses and other choice flowers.

Mr. Amos Perry, Hardy Plant Farm, Enfield, Middlesex, showed a striking mass of the new Achillea Perry's White, and also a new and attractive helenium named Autumnale rubrum. Delphiniums Mrs. Creighton and Mrs. Perry were in the exhibit.

Sweet peas were the main feature of the exhibit staged by Messrs. Thyne and Son, Union Street, Dundee. The firm also had hardy border plants in variety, phloxes showing up well. The sweet peas were beautiful flowers, strong in stem, and embracing the best peas of the day.

Messrs. Williamson, Gemmell, and Co., Argyle Street, Glasgow, made quite a miscellaneous exhibit, covering floral and vegetable subjects, and also ferns and foliage plants. A magnificent lot of begonias were brought all the way from Bath by Messrs. Blackmore and Langdon. There is no necessity to speak of the quality of the flowers, for it may be taken for granted the firm only shows plants or flowers beyond reproach. Messrs. Malcolm Campbell, Lim., Glasgow, exhibited a table of choice fruit of the best sorts, both hardy and exotic. Pineapples, bananas, grapes, figs, plums, peaches, and pears were all picked specimens.

Messrs. Wells and Co., Merstham, Surrey, showed a nice group of early-flowering chrysanthemums, all of which were bright, free, and useful garden sorts. The same firm showed perpetual carnations and herbaceous phloxes in variety. Mr. Wm. Leighton 36, Renfield Street, Glasgow, arranged an exhibit of crotons, palms, and ferns, and also showed a good collection of dessert and culinary apples. Messrs. Austin and McAslan, Glasgow, occupied a large space with a collection of decorative foliage plants, large hydrangeas, Lilium auratum, and choice ferns.

Messrs. Geo. Fairbairn and Sons, Botcherby, Carlisle, had a nice exhibit of sweet peas, Safrano, Rosabelle, and Lady Cynthia being attractive, even though among many other good ones. The exhibit occupied about a hundred feet of tabling. Mr. Jones, Kilkenny, showed good gladioli, Princeps, Loyal, Klondyke, and America being a few very distinct sorts.

A most interesting exhibit of grapes was sent from the Royal Horticultural Society, Wisley, comprising quite a large number of varieties, some of which are scarcely ever seen in cultivation. Of course those, for the most part, are small-berried varieties, but some of these are particularly fine in flavour.

ANDROSACE LANUGINOSA.

This is without doubt the loveliest of the androsaces when seen in large masses covered with flower. Its rosy-lavender blossoms, with yellow centres, commence to expand during the month of May, and are at their best about midsummer or a little later, but continue to bloom well into the autumn, it being no uncommon occurrence to see an example bearing a dozen or more flower-heads as late as mid-November. Between these two dates it is never entirely flowerless, but generally reaches its zenith of perfection early in July.

In their native altitudes the plants are exposed to severe frosts, and during the winter are covered with deep snow, but in our climate, with its alternations of frost and damp, muggy weather, the androsaces often succumb. The silky foliage is greyish-white in colour, and large specimens have the appearance of cascades of silver falling over the rocks. The mass here illustrated, which measures over four feet each way, is the development of two tiny plants put out from thumb pots three years ago on a sunny bank, in soil mixed with a large proportion of small stones and rough grit.

Androsace lanuginosa makes prostrate stems a foot or more in length. Cuttings may be made of these, and, if they are placed in pure silver sand, and kept close for a short time, they will soon root. Planted in the spring, a few inches apart, these will soon form an effective mass. Old stems cut back make stronger growth, and bear larger heads of bloom. The best position for this androsace is one where its growths may hang over perpendicular rocks.

The silvery, silky foliage often suffers considerably from damp in the winter, but is less subject to its effects when the growths are pendent, and are backed by rocks. Where it is grown on a flat surface, this should be covered with small, flat stones, in order to prevent contact with the soil. Fibrous loam and peat, with which a liberal allowance of rough grit and rock chippings is mixed, proves, in most cases, a satisfactory compost. Overhead moisture during the winter can, to a certain extent, be obviated by fixing a large pane of glass horizontally a few inches above the plant, or, in the case of large plants, by placing a glass light a few inches above them.

It is surprising what difference of opinion exists regarding the culture of the subject of this note. A certain writer, a very successful rock gardener, once wrote of it as "one of the easiest grown of all alpine plants," though, by the way, it is a native, not of the Alps, but of the Himalayas. Another writer, particularly well versed in the culture of alpines and such-like subjects, stated, on the other hand, that he found no plant more difficult to cultivate successfully. Between these two extremes many instances of partial success or failure are recorded. Those who experience no difficulty in growing the plant fail to understand why others are not as successful, while the unfortunates who are unable to prevail upon it to live wonder at the easily-gained triumphs of their more favoured brethren.

Even where Androsace lanuginosa has flourished for years it sometimes dies out unexpectedly. In one of the best rock gardens in Devon this androsace grew with astonishing vigour, and formed a mass six feet in length and three feet in breadth. This suddenly died, and for some years, though strong young plants have been tried again and again, and the whole of the old soil removed, and prepared compost of the best description substituted, it absolutely refused to grow.

WYNDHAM FITZHERBERT.

Kingswear.

ANDROSACE LANUGINOSA IN A DEVONSHIRE GARDEN.

The flowers are rose-lavender, and freely produced over a long period.

TRITELEIA UNIFLORA.

Commonly known as the Spring Star Flower, and passing under the name of Triteleia uniflora in gardens, this bright and interesting half-hardy, bulbous plant is now placed by botanists in the genus Brodiæa. A native of the southern part of South America, chiefly around Buenos Ayres, it has been known in gardens since the early part of last century. The colour of the flowers is reminiscent of the chionodoxas, which bloom two months in advance of the species under notice. In other respects they are quite dissimilar. In Triteleia the flowers are borne singly, or more rarely in pairs, on simple stems; the flowers are large, over two inches in diameter, and open flat; the segments are arranged in two series in the form of regular, pointed triangles, hence the popular name of Star Flower is suggested. Provided that a sunny position and moderate rich, well-drained soil can be given it, this triteleia will add distinction and interest to the garden in spring. The best results I have obtained were with bulbs planted on low, sunny banks, in company with Anemones pulsatilla and apennina, and Tiarella cordifolia. In the third year after planting the colony became so dense as to convey an impression similar to that produced by overcrowding from seed-sowing. To those who garden on limestone or chalky soils this is a bulb to naturalise freely, as under these conditions I have found it most reliable in flowering, and prolific in increase, and it is one of the least expensive to procure. It is best planted in autumn at a depth of two to three inches in the soil.

THOMAS SMITH.

LITTLE AND OFTEN.

When trying to show people the inadvisability of taking very heavy meals, it is a common thing to enforce the advice by giving as an illustration the difference between keeping up a fire with an occasional shovel of coals, and putting on a whole scuttle at intervals of four or five hours. This is an instance of the "little and often" system which is such a good one to adopt in many horticultural practices. The man to whom all gardening operations are a nuisance, and merely so much work to be done, likes to do a thing all at once and get it over, while the lover of gardening will keep his protégés under observation and attend to them according to their needs. Let us look at a few of the commonest routine operations of the garden which are best done by easy stages. The

Summer Pruning

of fruit trees is the first one that comes to mind. Every leaf removed from a tree or plant weakens it to some extent—considerably when the plant has only three or four leaves, and infinitesimally when it has hundreds. We have all seen plants and trees weakened permanently by having a large proportion of their foliage removed by slugs, caterpillars, or birds, and when we summer-prune a bush apple by removing three-parts of its summer growth at one time, or disbud a peach by rubbing off all the young shoots except the first and last on each twig, we are giving a serious check to the growth, from which it will take some time to recover, especially if the weather should turn cold shortly afterwards. If we had begun by doing a quarter or a sixth of it, choosing the strongest growths to start with, the energy of the tree would have been diverted into the remaining growth, and little, if any, check would have been given, but, on the other hand, each successive stopping or disbudding would have sent a little additional strength to the weaker growths, and thus the growth would have tended to become better balanced. This gradual stopping is specially valuable with wall plum trees which are growing vigorously above the wall, while the lower branches are becoming weaker. The strong shoots at the top of the wall should be stopped first, doing this as soon as the basal leaves are well developed, and then, after a week or so, applying the same treatment to the strongest of the breast shoots. The difference in the growth of trees which are treated in this way over a course of years, as compared with those with which no such care has been taken will be very marked. The work need not be made a labour of, for any odd five minutes can be used for the purpose.

Another practice which might be mentioned is that of

Manuring,

liquid or otherwise. All who have used nitrate of soda know that "little and often" is the rule to abide by, heavy doses sometimes injuring the roots, rendering plants unhealthy, or even killing them outright, while a slight dusting on the soil once a fortnight or three weeks, according to the weather, will work wonders. It is the same in principle with liquid manure, except that small doses are even more essential, especially for pot plants, where the soil is so likely to get sour. Heavy doses applied to the soil, besides the lessened efficiency and even injury resulting from their use, also mean greater loss from heavy rains. With mulching it is a mistake to use a large quantity at once, as it excludes air from the soil, keeps it cold, and prevents the material used becoming broken up into its simple elements, and so feeding the tree or plant as quickly as it should do. A small quantity about the end of May, when the soil is becoming warmed, followed by another layer a month or six weeks later, will conserve the moisture just as well, and by the end of August the whole mulch will be decayed and almost powdery.

Potting.

affords us another illustration. Some people, usually very inexperienced amateurs, though in some cases lazy ones, put plants into their final pots straight away. The result is that, unless watering is done very carefully indeed, the portion of the soil which the plant does not use for some time will become sour and the plant will suffer. On the other hand, when plants are moved from sixties into forty-eights, and from these into thirty-twos, and so on, each shift seems to give the plants an impetus in their growth, or a fresh start, which is especially noticeable if the plants have nearly exhausted their former confined root-run. With some plants, most noticeably with chrysanthemums, a darker colour may be noticed in the leaves within two days of the shift.

Thinning

must be mentioned in this connection. If seedlings are thinned in wholesale fashion, not only will harm probably be done by deferring the work as long as possible, so that the seedlings may be big enough to handle, but many of the best plants will be sacrificed. It is an operation that should be lightly touched, it may almost be said played with, at short intervals, in warm, growing weather every day or two, beginning with the thick clusters, which had better be pulled up entirely, as they are bound to be leggy, and then pulling them almost entirely where they are at all thick; only leaving a few of the strongest and sturdiest, at every thinning leaving the best plants, in which way we shall ultimately reduce a patch of many hundreds to a dozen or two. The same principle should be applied to the thinning of fruit, except that it is not necessary to remove completely any thick clusters, but always beginning where they are thickest and most badly placed, and leaving the best fruits. Those which are all of a size two or three weeks after setting will often vary a good deal a month afterwards.

Gathering of Apples and Pears.

Where trees are at all inaccessible it is a great mistake, at least with dessert fruit, to pick all at once, as they do not mature simultaneously. Where long ladders have to be used, it is, as a rule, scarcely advisable to adopt the practice of gradual gathering, as so much harm will be done to the trees by the ladders. But otherwise a beginning should be made on the fruits which look most mature three or four weeks before the usual season of the final picking, and this should be followed after a week or ten days by gently lifting them all, and only removing those which come off easily. It will generally be found that those which are obtained from the last gathering will compare very favourably with the earlier pickings. In this way every fruit is obtained at its best, and there is the minimum risk of loss from storms. In the case of pears, too, there is the added advantage that the season of a given variety is prolonged, in the case of some varieties doubled.

These notes must not conclude without a warning that there is one operation, and that the commonest in garden practice, which must not be done little and often, and that is watering. Water thoroughly or not at all, whether the subjects are in pots or in the open ground. In the case of pots it is better to water twice, at intervals of an hour, and then, except in hot weather, they will usually last over two days, so that it will not take much longer on the average. ALGER PETTS.

ALTHÆA FICIFOLIA.

A few days since, when passing through the highway facing the long block of ancient and picturesque houses at Horsham termed "The Normandy," formerly the residences of the Normandy Brotherhood, my attention was drawn to one or two plants of the fig-leaved hollyhock growing in the garden of what is known as the Priests' House. The plants occupy a corner of a small front garden, and had tall spikes of pale yellow or primrose-coloured flowers. The palmate leaves were not, however, large, and had only five lobes, but the small size of the leaves, and the slender flower spikes may, no doubt, be attributed to the poverty of the soil, and the crowding of the other hardy plants. I ascertained from the occupant of the house that the seed had been obtained a few years ago from a garden in Surrey.

Relative to the country of which Althæa ficifolia is a native, it may be remarked that in Nicholson's "Dictionary" it is described as a native of Siberia, whereas Paxton's "Botanical Dictionary" and Johnson's "Gardeners' Dictionary" gives the Levant as its home. All the publications agree in giving 1597 as the year of introduction. It would be interesting to learn whether the Levant or Siberia be correct.

It should be mentioned that there was no indication of the presence on the leaves of the dreaded hollyhock fungus, although plants of the hollyhock growing within a distance of three or four yards were suffering severely from the disease. This confirms the opinion generally held with regard to immunity of the species from disease, and suggests that by the hybridisation of A. ficifolia and A. rosea a disease-proof race of varieties might be obtained. WILLIAM GARDINER.

Horsham.

[Althæa ficifolia is a handsome species, and so closely resembles A. rosea, better known as the common hollyhock, that the only point of difference is the narrow lobing of the leaves, and this is variable, and sometimes the leaves are as broad and as little lobed as those of the hollyhock. It inhabits an extensive area from Persia to Siberia, South Russia, Syria, and Egypt. —ED. "G.M."]

Pink Cuttings.—These will now be well rooted, and can be planted out in their permanent quarters, or otherwise on a reserve piece of ground, for a season to develop into nice tufts for planting another autumn.—T. B. FIELD.

WORK AMONG CHRYSANTHEMUMS.

Mildew is again crippling hundreds of chrysanthemum plants, and the largest and healthiest leaves seem to be those most severely attacked. Certain varieties, however, have almost entirely escaped injury. I have often wondered why they are more immune than others, and find that the undersides of the leaves appear to be more glossy and smoother than those which fall a ready prey to mildew. Few suffer more than that old favourite, F. S. Vallis, but Reginald Vallis and Madame G. Rivol are sometimes almost denuded of all their leaves through bad attacks of mildew.

While the plants are outside I favour remedies applied in liquid form chiefly. When placed under glass fungicides in the form of either a powder or spraying solution may be used. Where the attack is confined to a few leaves on a few plants only flowers of sulphur may be put on; but when the attack extends to many plants, and is quite general, a spraying solution is the best. I have not found anything better than a solution of sulphide of potassium, prepared by dissolving one ounce in two and a-half gallons of clear water. It is, however, preferable to dissolve the rock sulphide in about one pint of water, then cork it up tightly in a glass or earthenware bottle for several days before mixing with the full quantity of water. Weak sulphide of potassium turns the water to the colour of milk, while the best sulphide makes the water resemble pale brandy, and discolours the woodwork brown when wetted with it. The undersides of the leaves of the plants should be thoroughly wetted when the solution is applied; a syringe fitted with a spraying nozzle being preferable for its application. To carry out the work as it should be place the plants on their sides on mats, or, better still, in a long wooden trough sufficiently wide to contain the plant without bruising the leaves. The surplus liquid can then be collected, and any waste avoided. Repeat the syringing just before the plants are placed in the houses. On the day they are housed dust some flowers of sulphur on the undersides of the leaves of all plants that have been treated for mildew outside. If given fairly good treatment under glass as regards ventilation, so as to avoid draughts, the plants will not suffer much from mildew before the show dates come.

Chrysanthemums always do better if kept in the open air as long as possible, but no good purpose will be served if they are kept out after the buds commence to open, but damage may be done to the blooms if they are left outside after reaching that stage. Some of the very late-flowering varieties are the best as regards bearing blooms of exhibition standard, and it is imperative that they be put under glass at a much earlier date than the others.

Last year I "timed" a number of the new varieties as a guide to their treatment this year, although they can rarely be depended on to come to time every season. I found that by housing the variety Mrs. G. Drabble the last week in September the buds showed colour on October 14, and were fully developed blooms on November 14. To have this, and several other good late varieties at their best on November 1 it is advisable to put the plants under glass on September 18. Abundance of air must be admitted to all such early-housed plants. According to my experience it is a good plan to commence on September 13, placing the plants on the floor of a suitable house every evening, or thereabouts, and taking them into the open air again every morning. By so doing they are not weakened, and the buds advance very considerably.

Instead of arranging them all in groups, and so closely packing them that the lower leaves are soon lost, stand individual specimens of the best and new varieties in odd corners of the structure, where plenty of light and air can reach them.

GEORGE GARNER.

CUNNINGHAMIA SINENSIS.

Upwards of a century has elapsed since this tree was introduced into British gardens, for it was originally sent home in 1804 by Mr. William Kerr on behalf of the East India Company. A native of Southern China, it is too tender for general cultivation in the British Isles, although it is often met with in the southern and south-west counties. The accompanying illustration depicts a specimen growing in the choice collection at Bury Hill, in Surrey, whilst other fine trees are to be found in the same county in the gardens of H.R.H. the Duchess of Albany, at Claremont, and in the gardens of H.R.H. the Duke of Connaught, at Bagshot. In Devonshire and Cornwall, however, it is met with as an even finer specimen, and examples are to be found between thirty and forty feet high, with trunks twelve to fifteen inches in diameter. As a rule, however, the older trees are less ornamental than the younger ones, for they lose their lower branches, and become very ragged without the nobility of aspect which attaches to an old battered yew or Scots pine. In many gardens it is found with several trunks springing from one rootstock, as is shown by the present illustration. This can often be traced to the tree being killed to the ground line by a severe winter, such as was experienced in 1894-1895. It is, however, one of several conifers which is able to regenerate itself by shoots springing from near the ground, and it is rarely that a severe winter kills a tree outright.

CUNNINGHAMIA SINENSIS.

A fine specimen in the gardens of Bury Hill, Dorking.

The species is araucaria-like in character, the leaves being linear-lanceolate, and two to three inches long, sharp-pointed, and thick in texture. The cones resemble miniature araucaria cones, being rounded, and one to one and a-half inches in diameter. They are borne freely on trees in the gardens of Sir Thomas Dyke-Acland near Exeter, and at several other places. Although the tree is usually grown from seeds, it may also be increased by means of cuttings, the best being those obtained from the upright shoots which spring from a trunk that has been cut back in the course of a severe winter. W. D.

NEW PLANTS, FLOWERS AND FRUIT.

SCABIOSA CAUCASICA MAGNIFICA.

An exquisitely beautiful variety of this well-known and highly-appreciated species. The flowers are larger, and of finer form than are those of the type, and the shade of lavender-blue is rather more intense. It is a valuable addition to the hardy perennials flowering at this season of the year. A.M., R.H.S., August 26. Messrs. J. Cocker and Sons.

LÆLIO CATTLEYA ETTRICK.

A bold and handsome hybrid, obtained from a cross between Lælio-cattleya Bletchleyensis and Cattleya Dowiana. In general aspect this form suggests L.-c. callistoglossa, but the flowers are larger and more richly coloured, and it is much finer than that beautiful hybrid. The flowers are of large size, the sepals and petals purple-rose, and the lip crimson, marked with gold A.M., R.H.S., August 26. Messrs. J. Veitch and Sons, Chelsea.

ODONTIODA BRUGENSIS VAR. EILEEN.

A distinct and attractive form of the fine hybrid raised some time since by Messrs. Sander and Sons in their Bruges establishment. The flowers are rose-purple, with deep purple blotch at the base of the lip, and a bright yellow crest. We illustrated this variety in our issue of August 30,

SCABIOSA CAUCASICA MAGNIFICA.

Flowers, lavender-blue. A.M., R.H.S., August 26. Messrs. J. Cocker and Sons, Aberdeen.

CATTLEYA HARDYANA MRS. WATERS BUTLER.

A distinct and attractively-coloured form F.C.C., R.H.S., August 26. J. Gurney Fowler, Esq., Glebelands, South Woodford (gardener, Mr. J. Davis).

of this fine species; the sepals and petals light rose, and the lip rich gold and deep purple. A.M., R.H.S., August 26. W. Waters Butler, Esq., Southfield, Edgbaston (gardener, Mr. R. H. Jones).

LÆLIO-CATTLEYA MARQUIS DE WAVRIN. ORCHIDHURST VARIETY.

A good variety of this well-known hybrid. The sepals and petals are deep rose, and the lip deep crimson. A.M., R.H.S., August 26. Messrs. Armstrong and Brown, Tunbridge Wells.

CHRYSANTHEMUM IMPROVED NORTHERN STAR.

A distinct and effective form of the well-known annual Chrysanthemum carinatum. The flowers are about four inches in diameter, regular in outline, the ray florets white, with yellow base, the latter colour forming a regular band round the dark coloured marbling. F.C.C., R.H.S., August 26. Baron Bruno Schroder, The Dell, Englefield Green, Surrey (gardener, Mr. E. Shill).

CHRYSANTHEMUM LILY REED.

A distinct cactus variety, with long, elegantly-arranged florets; the colour is lemon-yellow, and the flower, which is highly finished, is of large size. A.M., R.H.S., and F.C.C., N.D.S., August 26. Mr. H. Shoesmith, Woking.

Prince of Orange.—A collarette variety with rather large flowers of good form; the ray florets deep orange-salmon, and the great merits of this variety is the length and rigidity of the flower stalks. A.M., R.H.S. and F.C.C., National Dahlia Society, August 26. Mr. C. Turner, Slough.

PÆONY-FLOWERED DAHLIA APHRODITE.

Flowers large, pure white. A.M., R.H.S., August 26. Mr. C. Turner, Slough.

BRASSO-LÆLIO-CATTLEYA THE BARONESS.

A remarkably handsome hybrid, derived from a cross effected between Brasso-cattleya Mrs. J. Leeman and Lælio-cattleya Ophir. The flowers are of medium size, and good form; the broad sepals and petals are bright yellow, and the fringed lip rich yellow, marked with red lines and a rose-brown disc. A.M., R.H.S., August 26. Messrs. Dobbie and Co., Edinburgh.

DAHLIAS.

Aphrodite.—A charming variety belonging to the pæony-flowered section. The blooms are about six inches in diameter, have three rows of somewhat regularly arranged ray florets, which are pure white, and the disc bright golden-yellow. One of quill florets a lighter shade of the same hue. The blooms are lightly poised on stiff, wiry stems. A.M., R.H.S., and F.C.C., N.D.S., August 26. Messrs. Dobbie and Co.

Tusca.—A collarette variety, with medium-sized flowers of a rich crimson colour, with white quills. Dwarf in growth, and free in blooming. A.M., R.H.S., and F.C.C., N.D.S., August 26. Messrs. Dobbie and Co.

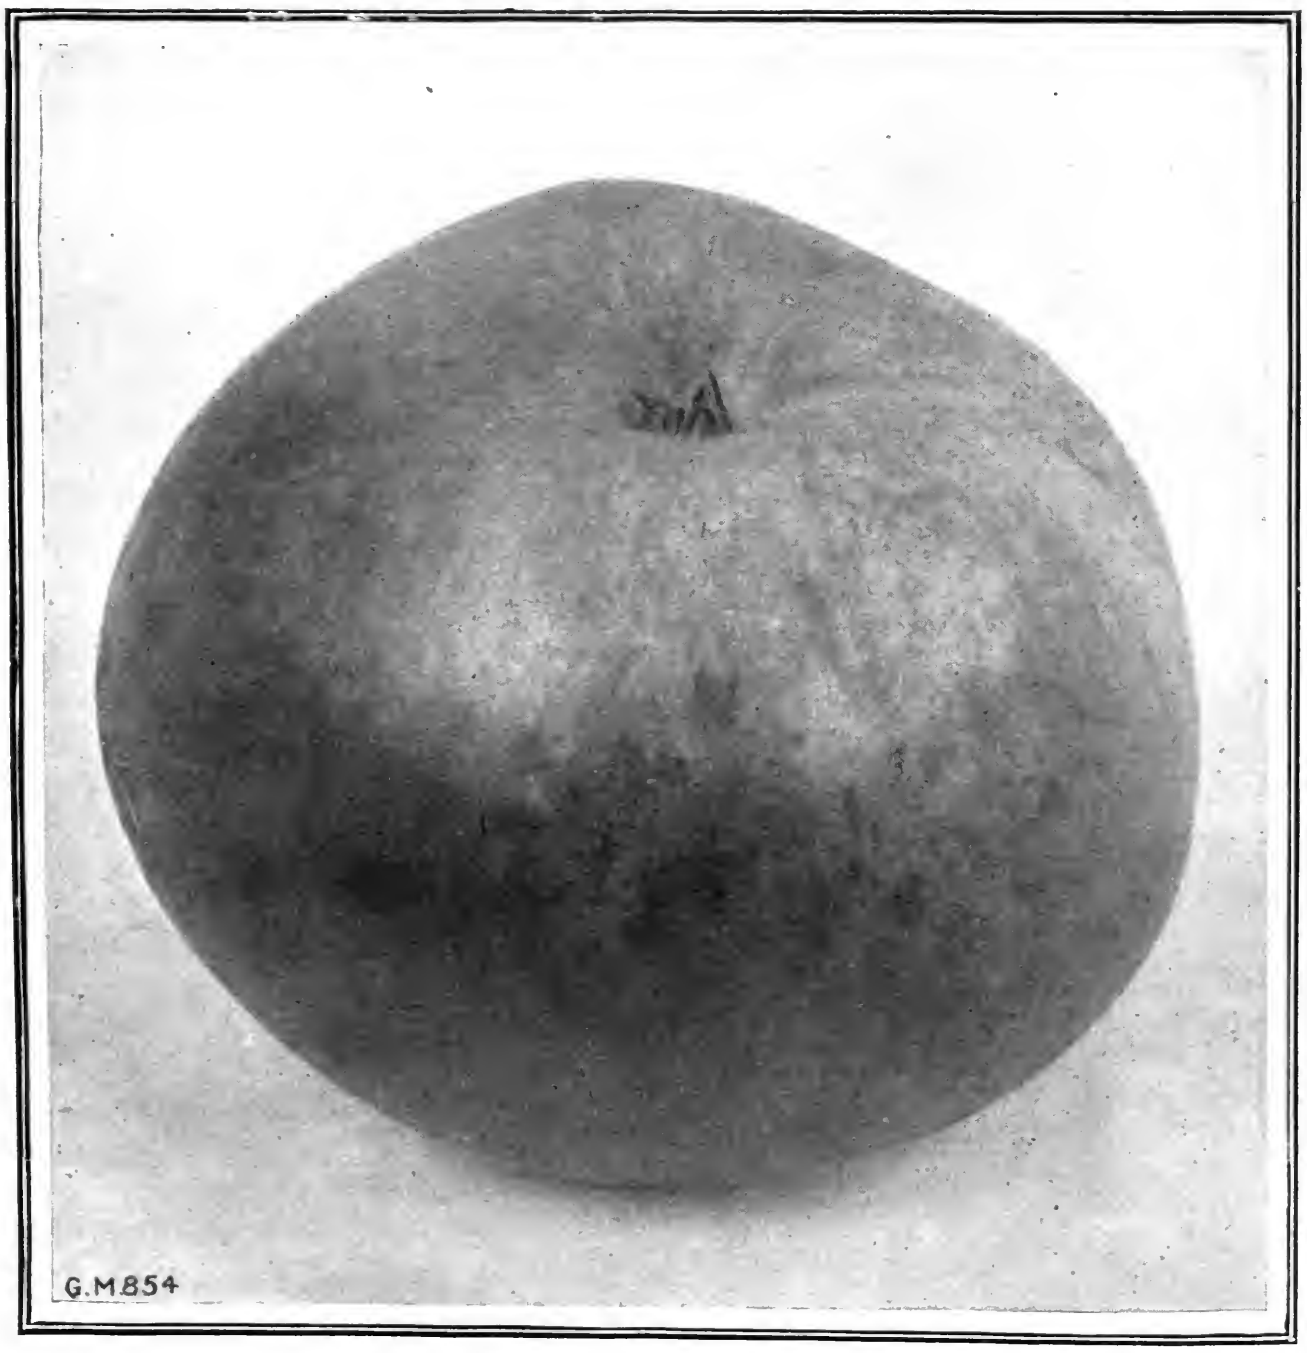
Regulus.—A distinct pompon; the blooms of exquisite form, and the colour bright ruby-purple. A.M., R.H.S., and F.C.C., N.D.S., August 26. Messrs. J. Cheal and Sons, Crawley.

GLADIOLI.

Lady Faire.—A charming variety of distinct character; the flowers large and of good form, the colour cream-white, passing to pure white, and marked with a crimson blotch on the lower segment. Messrs. Kelway and Son, Langport.

Lady Northcote.—A superb variety, the flowers of high quality, and so arranged as to form a noble spike; the colour buff-yellow, tinted pink towards the margin. A.M., R.H.S., August 26. Messrs. Kelway and Son.

Mrs. Bromet.—A remarkably beautiful variety, with flowers large in size, of superb form, and of a pleasing sulphur-yellow, marked with purple in the centre. A.M., R.H.S., August 26. Messrs. Kelway and Son.



APPLE MAIDSTONE FAVOURITE.

An early dessert variety. A.M., R.H.S., August 26. Messrs. G. Bunyard and Co., Maidstone.

MONTBRETIA QUEEN ADELAIDE.

A welcome addition to the already strong list of montbretias now in cultivation. The plant is robust, with stout, well-branched flower spikes, and the flowers are between three and four inches in diameter, and are brilliant orange, with yellow centre. A.M., R.H.S., August 26. S. Morris, Esq., Earlham Hall, Norwich (gardener, Mr. Henley).

ROSE MRS. ANDREW CARNEGIE.

An exceedingly beautiful white hybrid tea which is described as having been raised from a cross effected between Frau Karl Druschki and Niphetos, and was awarded the gold medal of the National Rose Society at the exhibition held in the Royal Botanic society's garden. 1912. At the exhibition held at the same place in July last the raisers were successful in taking the premier award for eighteen blooms, shown in a basket, of any rose other than a H.P., T., or N., with finely-developed blooms of Mrs. A. Carnegie, and this basket was illustrated in our issue of July 12. A.M., R.H.S., August 26. Messrs. J. Cocker and Sons, Aberdeen.

APPLE MAIDSTONE FAVOURITE.

An early dessert apple of quite exceptional promise, both for home use and market supplies. The fruit is of the size and shape shown in the illustration, with a rather deep eye, short stalk, and brilliantly-coloured skin, the latter being streaked red and yellow. The flesh is firm, crisp, juicy, and pleasantly flavoured. It originated as the result of a cross between Irish Peach and Beauty of Bath, and for market purposes should be of value for succeeding the second of the two varieties mentioned. The attractive colouring of the fruit, combined with high flavour, bespeak popularity in the markets. A.M., R.H.S., August 26. Messrs. G. Bunyard and Co., Maidstone.

Bouvardia Humboldti corymbiflora.—Autumn is generally regarded as the season of the bouvardias, but this is, as a rule, at its best during the summer months; indeed, so free does it then flower that it is often employed for bedding purposes. When used in this way, two-year-old plants are preferable to the young ones, as those struck in the spring have not time to attain an effective size by the bedding season. It is in many respects different from most of the bouvardias that are so much grown for greenhouse decoration; B. Humboldti corymbiflora is of upright growth, while the leaves are quite smooth. The flowers, too, are much larger, with a particularly long tube of the purest white, and deliciously scented. The cuttings of this kind take somewhat longer to root than most of the others.—K.

NOTES ON THE APPLE AND PEAR CROPS.

Of all the hardy fruit crops ripened in this country, the apple is of the greatest economic value, and ranks as a national asset of some importance. With its cultivation is bound up a wide variety of interests, and grower, distributor, and public alike stand to gain when the apple harvest is full and generous. Widely different reports are at present in circulation regarding this year's crop, but so far as our trees are concerned the quantity is quite up to the average, and I believe this fairly represents the district.

The early months of the year fostered premature swelling of the buds, but the low temperature and sunless days that prevailed throughout March and April arrested growth, so that at flowering-time the trees were quite seven to ten days later than a year ago. Blossom was abundant, the flowers perfect, and fruit was freely set. Unfortunately the season has been decidedly cool, and an interval of six weeks elapsed, from the middle of May to the end of June, during which no rain fell; consequently the fruit at present is under average size, and this is likely to continue unless rain, accompanied by greater warmth, comes within the next few days. The importance of moisture at the roots cannot be overrated, as where trees were taken in hand early, and systematically watered and mulched, the fruits are at least 25 per cent. larger than where no such assistance has been given. Early thinning tends to the same end, for even on the same tree where boughs have but a single or few fruits, these are appreciably larger than those on branches having the fruit crowded.

No recent year stands out in greater relief than the present for the infestations of insect pests, and from these the fruit trees have received every care. Aphides of various kinds have only been kept under by constant spraying and syringing. Grease-banding has been practised to some extent, and the foliage has benefited from the absence of caterpillars. Codlin moth grubs are not so prevalent as a year ago, but the ravages of American blight are still patent on some trees, Gascoigne's Scarlet being one of the earliest to succumb to this insidious pest.

Of the varieties that stand conspicuous for abundance of fruit, Stirling Castle, The Queen, Jas. Grieve, Allington, Coronation, Grenadier, Cox's Pomona, Ribston Pippin, Alfreston, Warner's King, Worcester Pearmain, Lady Sudeley, Duchess of Oldenburg, Lord Derby, Norfolk Beauty, Peasgood's Nonsuch, Tyler's Kernel, Wellington, Lord Suffield, Beauty of Kent, Tower of Glamais, and Lane's Prince Albert are all well above the average, and, with the exception of Cellini, Coronation, and Grenadier, were also up to average a year ago.

Ecklinville, Blenheim Pippin, Charles Ross, Mère de Ménage, New Hawthornden, Betty Geeson, Emperor Alexander, and Old Nonsuch carried heavy crops last season, but on these only a sprinkling of fruit is to be found this year.

Among pears there is a short crop, the one notable exception being Williams Bon Chrétien, which has here carried a full average crop of excellent fruit during the past three years.

Plums and gooseberries were practically failures, but Royal Sovereign and Giroux's Late strawberries, Superlative raspberry, and Boskoop Giant black currant have carried enormous crops of fruit of the highest quality.

THOS. SMITH.

Coombe Court Gardens.

SEASONABLE NOTES ON CLIMBING ROSES.

In almost all districts the early part of this spring was exceptionally trying to roses, and perhaps to none more than to the so-called tender climbers. A very mild and damp winter resulted in more or less continuous growth in the sheltered positions that are naturally selected for this class of rose; and when the cold, unkind spring came, we had a larger amount of young wood than was at all desirable with the almost certain prospect of spring frosts. The enormous amount of insect pests that actually seemed to revel in the unsuitable weather conditions for roses was a very great trial to them.

Positions for Climbers.

The main object of these notes is to point out what I have long thought a common error in the selection of sites for notoriously tender climbing and pillar roses. It is quite natural and right to afford these a well-sheltered position, but to have them practically shut up in a hot south-west or south-east corner is going to the extreme in the matter of shelter. Their tender and seldom well-matured wood does not become sufficiently matured to pass through the winter. In addition to this, we are encouraging early growths on what are naturally precocious varieties. It should be understood that in a sheltered position the extreme cold of an early spring morning is too great a contrast to the quite greenhouse temperature that is experienced when the sun rises.

To afford due protection from inclement weather is correct enough, but we might well try not to overdo this. I have more than once noticed how much more satisfactory many of the tender roses have been when in a colder position, so long as it was sheltered. As the majority of this class prefer a rather drier root run than colder places often afford, I would suggest a little more care in providing this, and raising the soil a little. Some of the best blooms of Rosa sinica anemone roses I saw during the past season were upon a north-west bank; and it is just such positions that are free from the sudden changes caused by a bright sun following a cold night and morning.

I have found L'Ideal, Climbing Perle des Jardins, the now too seldom seen Lamarque, Climbing Devoniensis, Fortune's Yellow, and Maréchal Niel doing better, or at any rate longer-lived, in such situations than when closed in a hot corner. Of course, one takes care that the plants are not fully exposed to keen frost-laden winds, but such protection should not be so near as to smother the roses in any way.

The Pruning of Climbers.

By the time this appears in print, all but those which are really perpetual will have done flowering. I am alluding to those varieties which seldom afford any later flowers after the first glut of summer bloom is over—such as the majority of Climbing Polyanthas, Ayrshires, and Wichuraianas. There can be little doubt that most of these produce their best crop of blossoms from growths made from now onward, which will, in all probability, flower throughout their length if properly matured. Therefore we should induce a good supply of such wood, and, in order to secure this, a certain amount of summer pruning is almost a necessity. Unless we use the knife now, the result will be a closer and more crowded growth than desired. The quantity of short lateral growths crowding the centre of the plants is comparatively useless against a smaller number of long and healthy shoots, which last are much better when secured from the base of the plants so far as possible. I do not advise the entire or complete cutting down that is sometimes practised, but would do the pruning in two or three operations, and thus avoid seriously upsetting the balance of root and wood growth.

In the case of many roses used for pegging down in beds, the removal of the long shoots as soon as they have finished flowering is very essential. This helps towards the better growth of successive shoots from the base of the plant, and also allows of the better cultivation between—work that is often difficult, if not impossible, while the whole surface of the beds is crossed and traversed by pegged-down growths. Care, and a little more consideration in thinning and pruning of climbing roses during summer, is well repaid if one bears in mind the object aimed at, and gives a little thought to the natural growth.

The prompt removal of decayed flowers or developing heps is not sufficiently attended to in the open. Unless it be desired to obtain heps or berries from such as the Rugosas and a few more, it is very important to do away with any tendency to ripen seeds, which has a serious check upon future growth and blossom. Nor do I think we give enough attention to cutting back the growths a little at this time, it being better to keep new breaks as low as possible, and so avoid the stretch of dormant buds or eyes so often met with between the new terminal shoots and the older wood. This might almost be styled another form of summer pruning, and it is surely well to cut back to the most serviceable point whenever using the knife.

Rosarian.

TURNIPS FOR WINTER USE.

Sweet, crisp roots of this vegetable are appreciated at all seasons of the year, but much more so during winter and early spring, when other kinds are less plentiful. To obtain an ample supply of fresh roots it is necessary to make two or three sowings of seed between the beginning of August and the end of the second week in September, regulating them according to the district in which the cultivator resides, the variety grown, and the fertility of the soil. It is almost impossible to produce tender roots of high quality unless the ground on which they are grown be in a high state of cultivation, and an abundance of moisture available to enable the plants to make a quick growth. When the roots are a long time in attaining their usual size they become tough and stringy, and indifferent in flavour.

A quarter from which early peas or potatoes have been taken is a suitable place for growing this crop, and in most gardens there will not be much difficulty in selecting a suitable position. The ground should be forked over, and all lumps of soil broken down as fine as possible in order to obtain a good tilth for sowing the seed. When this has been done give the plot a dressing of superphosphate or dissolved bones at the rate of about four or five pounds to the square rod, to which may be added about half that quantity of kainit. Failing these fertilisers give a liberal dressing of Peruvian guano, dried blood, or other quick-acting manure. Should the ground be very dry at the time a liberal soaking of water will be highly beneficial, and if this be given allow the soil to remain undisturbed for a time before raking it down. Should the soil be heavy and of a retentive nature, the raking of the surface may be deferred until the following day, when it will have become sufficiently dry to be trampled upon without adhering to the boots. If, on the other hand, it is light and gravelly, this operation may be performed in the course of a few hours after watering, especially in bright weather. Drills may subsequently be drawn from a foot to fifteen inches apart according to the variety intended to be sown and the quality of the soil. As some kinds make much larger foliage than others, it is obvious that the distance between the rows must be so regulated as to afford the variety room for its full development without there being any loss of space. For the strap-leaved varieties twelve inches between the rows will be sufficient, while for the other kinds from fifteen to eighteen inches will be none too much, as the plants bulb more freely and grow more sturdy if allowed ample room. The drills at this time of the year should be drawn rather deeper than in spring, so as to give more soil for covering the seeds. This will assist in retaining the moisture round them, and cause germination to take place more quickly.

When sown in very shallow drills, unless the soil is kept moist, the seeds are often subjected to dryness just as they are germinating. When this happens the young plants die off and the crop becomes irregular, therefore it is essential that the soil be kept moist. Birds are sometimes troublesome, but not so much at this time of the year as early in the spring, there being now ample food for them in the fields; but care should be taken to ward them off until the plants are large enough to need no further protection. When three or four rough leaves have formed thinning should be done, leaving the plants from six to nine inches apart according to the amount of foliage they are likely to produce.

Should the weather be dry it is essential the plants be well supplied with moisture to keep them growing. Frequently during August and September the weather is hot, and as the soil at this period has become parched, progress will be very slow unless some assistance in the shape of stimulants is given until the roots have extended to some depth in the soil.

We have usually made three sowings for the winter crop, the first about the second week in August, which consisted of such varieties as Red Globe and Green-top; while for later sowings the White Stone, All the Year Round, and Strap-leaved. We have made sowings as late as September 10 with excellent results, and when the winter has been mild these late sowings have proved invaluable in spring. Taken up in March, and removed to a cool place, such as to the foot of a north wall, they may be kept fresh until the roots from the spring sowings are of a suitable size for use.

It need scarcely be necessary to point out the advisability of keeping the plants free from weeds, especially during the early stage of their growth, for if these are allowed to make headway they are sure to retard the growth of the turnips. In very severe weather it is also advisable to take up sufficient roots for a week's supply, as it is difficult to lift them when they are frozen, especially where the soil is heavy. It is a good plan to cover a portion with litter should there be an appearance of severe frost, for the roots lose their sweet flavour when stored for any length of time. There is also another use to which this vegetable may be put, that is providing greens early in spring. It sometimes happens that the green tops are very useful, especially after a severe winter, when the broccoli and winter greens have been killed by the frost; therefore it is always advisable to sow a good breadth of late turnips, for if the roots are not wanted they will provide an abundance of valuable green food if allowed to stand until the end of March or early in April.

H. C. Prinsep.

WORK FOR THE WEEK.

CONSERVATORY AND GREENHOUSE.

CHRYSANTHEMUMS.—A house must be made ready for sheltering plants of the large-flowering kinds on which the buds are showing colour. Such buds are in danger of decaying should moisture settle on them. The flowering may be considerably retarded by placing them in a house with a northern aspect. The structures must also be prepared for housing the main batch of plants, as, although it may be too early yet to bring them indoors, it is wise to be in readiness should severe frosts be imminent. The late varieties will be the better if left outdoors as long as possible, but provision must be made to readily shelter them from early frosts. A temporary wooden structure may be erected, over which canvas blinds can be easily adjusted on cold nights. Before bringing chrysanthemums indoors it is a good plan to syringe them with a strong solution of soft soap and sulphur.

CLIMBING ROSES.—These are still in active growth, therefore they must be liberally supplied with water. Examine them periodically, and remove weak, useless growth. The flowering wood must be well exposed to light and air, so that it may become thoroughly matured. This is especially necessary in the case of those plants which are required for early blooming. Should aphis appear fumigate lightly with a nicotine compound.

HOUSING PLANTS.—It is time now that all greenhouse plants which are growing in cold frames be placed indoors. The opportunity should be taken when the houses are empty to give them a thorough cleansing. Any whiting or similar substance which has been employed for shading should now be washed off the glass, using the blinds only on bright sunny days, as it is important the plants should have all the light possible. Cyclamen, primulas, bouvardias, winter-flowering pelargoniums, etc., should be placed as near to the roof glass as possible. See that the pots are clean, and the plants are free from insect pests before bringing them indoors. They will need abundance of air for some time after they are removed to their indoor quarters.—E. HARRISS, Lockinge Park Gardens.

THE ORCHID HOUSES.

SEED SOWING.—Seed that is ripening at the present season of the year should be sown without the least delay, so that full advantage in the process of germination may be derived from the light now available and the favourable outside conditions. I consider that very little is gained by sowing seeds of epiphytal orchids after the end of September, and it is therefore better to wait until the turn of the days. Unless one has special facilities for the treatment of late autumn-sown orchid seeds, they make but little advancement, and frequently remain in a semi-dormant state. Even with every means at command to assist germination they do not make much progress until after the new year. In the case of seeds of cypripediums and other terrestrial kinds that take a long time to germinate, I do not think it matters much at what season of the year the seeds are sown, but it is preferable to sow them immediately they are ripe, rather than to keep them back, and sow them when the conditions are more favourable in the spring of the year. It is more than probable that when seeds of the large-seeded kinds are kept, after they have ripened, they will not germinate. Odontoglossum seeds are also best sown as soon as the seed pods ripen, although it is advisable to keep back a portion of the seed in cases where the maturity is reached late in the year, and make a second sowing after the days begin to lengthen. Odontoglossum seed sown now will germinate nearly as quickly as in the spring season, and the seedlings usually make considerable headway, so much so that they become far enough advanced for removal from the seed beds in the early months of the year.

PRICKING OFF SEEDLINGS.—This is a suitable time to transfer seedlings from the seed beds to the store pots. It will generally be found that where the young plants have developed their first leaf they commence to produce roots from the base of the growth. If plants are shifted in this state they soon become established in the fresh compost. The operation of transferring the small plants from the seed bed is a delicate one, and must be done with every care, due caution being necessary to avoid injury by bruising. I find a large pin with its point hammered flat as suitable as anything for the purpose, or a pointed soft stick will also answer the purpose. It is generally a question of room, where seedling raising is practised in most private gardens, and we have to overcome the difficulty of providing space by placing several seedlings in the same pots, but where there is ample room it is advisable to give them separate pots, even if they have to remain a little longer in the seed bed until they are large enough to be treated separately. There is no doubt that plants are not so liable to suffer from damping where grown separately, as when several occupy one pot. The potting compost used for all seedling orchids should not be coarse, and should be of the same nature as that found suitable for the parent plants. The pots used must be clean, and well drained. Keep all newly-potted seedlings carefully shaded from strong light until they have become well established, and maintain plenty of atmospheric moisture about them.—H. J. CHAPMAN, Oakwood Gardens.

HARDY FRUITS.

PEACHES AND NECTARINES.—Keep all sub-laterals on peach and nectarine trees removed as fast as they appear, and train the leaders straight from the base. Keep the foliage free from red spider, and the roots well supplied with water, especially in the warmer parts of the country and where the soil is light and well drained. When the fruits have been gathered the trees should be carefully attended to, and the shoots not required should be cut out, the aim being to keep the heads rather thinly trained, so that the wood may by the end of the season have thoroughly ripened. Take notes of those trees that, owing to an excess of vigour, have failed to fruit satisfactorily, and prepare for lifting the roots and pruning them at the end of October. Also make notes of trees that are of no use and grub them out as soon as time will allow. Prepare the borders for new trees, it being much easier where wheeling, etc., is to be done to push along the work in dry weather, so that, as soon as planting time arrives the trees may be put into their places before the soil becomes cold. Choose the kinds required well in advance, and when making the selection see that the varieties are of the best, and that they will maintain a long supply of good fruits. With careful attention peach and nectarine trees bear as regularly as most other kinds of fruit. After many years' experience, I should, if committed to one variety, choose Dymond. The fruit has a real Royal George flavour; the tree a strong constitution.

FIGS.—Old trees that are bearing good crops of fruits will be all the better for having the border thoroughly deluged with liquid manure; the fruits will then swell to a much larger size. Keep the shoots neatly trained and avoid overcrowding. Fig trees require ample room, and light and air, to mature the medium-sized growth, and a firm root run also. Keep the trees netted over should birds prove troublesome, and use light muslin bags to prevent destruction by wasps, these latter being very numerous this season.

VINES.—These must be attended to at intervals to keep the leading growths secured to the walls or trellises. All lateral growth should be closely pinched two or three joints above the bunches, and, in some cases, one joint will be quite enough to allow. Sub-laterals may be removed entirely, with the exception of the one at the end of the shoot, and this will need to be stopped at one joint. Should mildew put in appearance, dust all the affected leaves with sulphur, and syringe later with clean soft water to thoroughly cleanse the foliage.

STRAWBERRIES. — Autumn-fruiting kinds must not be overlooked; remove useless runners, keep the beds clear of weeds, put clean straw under the trusses of fruit, and well water the plants if the roots are in too dry a state. Should red spider prove troublesome syringe a few times with clean water.—H. MARKHAM, Wrotham Park, Barnet.

THE KITCHEN GARDEN.

MAIN CROP ONIONS.—The bulbs of spring-sown onions will, in most parts of the country, be well matured, and even those of strong growth will, if the tops were bent as advised in a previous calendar, be fit for lifting. If space is available in some sunny pits or cold frames, with their face to the south, the crop may be placed in them to dry thoroughly, the lights being put on during rainy weather. Where these conveniences do not exist the bulbs must be left on the ground, turning them over every other day. A wood trellis is useful on which to lay the bulbs. All thick-necked bulbs should be stored apart from the others, and used first.

SPRING CABBAGES.—The land should be prepared for the planting out of this most important crop. It is advisable to select two positions to ensure a plentiful supply of tender cabbages next spring. Select a warm sheltered border for the earliest varieties and an open position for the later and larger types. Land recently cleared of onions is most suitable for the later varieties; this only needs to be well hoed over and raked to be in readiness for planting. In any case the soil should be made very firm to induce sturdy growth. The very early small cabbages may be set out in rows fifteen inches apart and nine inches from plant to plant; an additional three inches may be allowed for medium-sized varieties, and large-growing cabbages should have another three inches each way. Keep a sharp look-out for grubs, which frequently attack the plants, eating them off just under the surface.

POTATOES.—As soon as the tops have decayed, no time should be lost in lifting the main and late crop potatoes. In digging, care must be taken not to damage the tubers with the fork, and to choose a dry day for the work. Damaged tubers or those having a diseased appearance should be put to one side, and those suitable for planting should be stored apart in a cool, dry place.

LETTUCE.—Plant out as soon as possible a good breadth of these plants, choosing for them a border in a sunny position. Ground that was well manured for some earlier crop will need only a moderate dressing of soot and wood ashes; to heavy soils give a liberal application of well-rotted leaf-mould and road scrapings. Some kind of protection will be needed during severe weather. More seeds may now be sown of the hardy winter kinds for planting in cold pits and frames. A suitable variety for the purpose is Hardy Hammersmith.—W. MESSENGER, Woolverstone Park Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Dundee Floral Fete.

AUGUST 28, 29, and 30.

The Dundee Horticultural Society is well over a half-century old, and for a long series of years its annual floral fete has been well organised, well patronised, and successfully carried out. The officers and committee form an ardent body of horticultural enthusiasts, and all strive hand in hand to secure success. The result is that no show beyond Edinburgh can compare with Dundee for extent, variety, and excellence.

Perhaps the most striking feature was the big display of stove and greenhouse plants shown by gentlemen's gardeners and amateurs in their respective sections. The Dundee amateurs are working men who do their gardening in their leisure hours, and many of these ardent cultivators possess small houses filled with shapely, well-grown crotons, bougainvilleas, cordylines, and caladiums, and of these their best were, as usual, exhibited in first-class style.

PLANTS—OPEN SECTION.

A class was provided for tables of stove and greenhouse plants, 12ft. by 7ft. There were three entries, but we were not greatly impressed by them, as all three exhibits were marred by overcrowding. Mr. Jas. Beats, gardener to Mrs. W. L. Rouse, Binrock, took first prize. His centre and four corners were built up with small bright crotons, and over a groundwork of nephrolepis, adiantums, and other ferns, rose the flowers of Clerodendron fallax, Schizanthus Wisetonensis, celosias, etc. The second prize went to Mr. J. Bethel, The Grange, Monifieth. Mr. Geo. Scott, Seathwood, Dundee, third.

Three flowering and three foliage plants brought good entries, the winning set being staged by Mr. Geo. Reid, who had a grand specimen of Asparagus plumosus, a nicely-flowered Statice intermedia, and anthuriums, bougainvillea, etc. Mr. Jas. Beat took second prize. Mr. Geo. Scott scored for two double begonias, followed by Mr Thos. C. Brown, Balcairn. Mr. Scott also took the lead with two zonal pelargoniums showing specimens carrying fine trusses; the second prize went to Mr. J. G. Clarke, Elmslie. Mr. Beat, Binrock, had leading honours for three crotons, Mr. Jas. Bethel following closely for second place.

Mr. Geo. Reid, Invertay, obtained premier honours for six stove and greenhouse plants in nine-inch pots, followed for second place by Mr. Jas. Beats. There were some good, well-grown specimens in this class. Mr. J. Bethel had the best three coleus plants, being closely followed by Mr. Jas. Beats. The winner for three dracænas was Mr. Wm. Grieve, Hazelwood, Broughty Ferry. Four British ferns were well shown by Mr. Jas. Bethel, who received first prize. Adiantum capillus veneris O'Brieniana was a beautiful specimen, as also was Athyrium angulare divisilobum densum Grimondi. Mr. Geo. Reid, Invertay, was second in this class; and Mr. T. Morrison, Gowrie House, Perth, came third. There was a nice display of British ferns in 6in. pots. Mr. Jas. Bethel once more obtained highest honours, with a choice set including Trichomanes radicans, Osmunda regalis cristata minor, Athyrium filix fœmina cristata Walkeri, A. f. f. congesta Edwardi, Adiantum capillus veneris magnificum, and Polystichum angulare congesta Lylei. Mr. T. Morrison came in second. The four best selaginellas came from Mr. Geo. Reid, Mr. Jas. Beats taking second prize.

The class for four exotic ferns in not less than three genera, constituted an interesting feature. Mr. Geo. Reid showed two beautiful gymnogrammas, a finely-crested nephrolepis, and a polystichum. Mr. Jas. Beats was second. Mr. Geo. Reid added to his successes by taking the highest awards for six exotic ferns in six-inch pots, and for six table plants, in both classes showing very nice plants. Some really fine cacti were exhibited by Mr. Robt. Birse, Carmichael Street, Dundee, who worthily received first prize for his finely-grown specimens. Cereus pernviana monstrosa was a capital specimen,

STOVE AND GREENHOUSE PLANTS AT DUNDEE.
Exhibited by amateurs who do not employ a gardener.

and Echinocactus Grusoni was good, while Mammillaria rubriosinia was beautifully developed and freely furnished with its crimson spines.

Although so late in the season, there was a capital display of alpine plants in pots six inches in diameter. The class for twenty plants, distinct, brought four good entries, and there was quite a nice bit of colour among the several collections. Mr. W. T. Morrison led the way, his exhibit containing, among other subjects, good examples of Arabis lucida variegata Acænaglumacea, Sedum kamschaticum variegatum, and Saxifraga longifolia. Mr. Robt. Birse, 28, Carmichael Street, Dundee, was second with beautiful examples.

PLANTS—AMATEURS ONLY.

Some capital stove and greenhouse plants were shown in the amateurs' section, and the first prize and Corporation Challenge Cup for three flowering and three foliage

plants were awarded to Mr. A. R. Easton, Lochee, who showed a well-flowered bougainvillea, rondeletia, and oleander, with a cocos, croton, and Yucca gloriosa variegata for foliage plants, all of which were of great excellence. Mr. Robertson, 6, Blyth Place, Dundee, was a good second. For two flowering and two foliage plants pride of place was given to Mr. W. Robertson, Mr. Easton being second, and Mr. R. H. Lowe, Wolseley Street, Dundee, third. Mr. Robertson scored another success with three foliage plants, staging a beautifully-grown cordyline, together with Asparagus plumosus and a fine yucca.

British ferns in threes were good, and the winning set was that shown by Mr. D. Smith, 10, Cleghorn Street, Dundee. Mr. W. Robertson, was a capital second. Mr. John Denholm showed three flowering plants in distinct varieties, for which he received first prize, the second going to Mr. John Ogilvie, 12, Rosebery Street, Dundee,

The amateurs' class for alpines was another strong one. Ten plants were required, and there were four entries. The first prize exhibit contained Nertera depressa, which, if hardy enough hereabouts for rockery work, is better behaved in Scotland than down south. The exhibitor was Mr. T. Shephard, Bridgend, Perth. The second prize was awarded Mr. Jas. G. Mathew, Inverary.

Mr. Easton had some grand cacti, taking the leading award for half a dozen. His specimen of the old man cactus was remarkably good. The class for three exotic ferns drew three entries, the best being shown by Mr. Wm. Dodds, Strathmore Road, Dundee, Mr. A. R. Easton and Mr. W. Robertson securing second and third prizes Mr. John Denholm took the lead with three good selaginellas, Mr. W. Robertson following. In the south we scarcely ever see tricolor pelargoniums exhibited, but the class for one tricolor and one bronze-leaved brought out seven entries. The plants were trained on wire frames, and the foliage was beautifully coloured. Mr. R. H. Lowe, 1, Wolseley Street, Dundee, took the leading place, Mr. Jas. Fyttes, 381, Clepington Road, and Mr. D. Craig, 21, Morgan Street, taking the other awards.

CUT FLOWERS—GARDENERS' SECTION.

The class for a table of cut flowers, excluding orchids, 10ft. long by 6ft. wide, had four good entries. Mr. Jas. Beats, Binrock, Dundee, took the coveted award. His centrepiece was a massive vase filled with Liliums speciosum roseum and album with Francoa ramosa and Humea elegans. At the corners were tall vases of carnations, chrysanthemums, roses, and liliums, and the table was filled in with smaller vases of clarkia, sweet peas, agapanthus, statice, and other suitable flowers. Mr. Geo. Scott, Seathwood, Dundee, took second prize. Third prize went to Mr. John Simpson, Panmure Gardens.

There was strong competition in the sweet pea classes, that for twelve bunches forming the opening class. In this there were nine entries. Mr. J. H. Crosby, The Ross, Comrie, took the leading position, his flowers being fresh and large in size on good, but not coarse, stems. Mr. Geo. Reid, Ruken Vale, Downfield, second; and Mr. Geo. Milne, Burnside, Dunnald, Montrose, third.

Mr. G. Reid, Invertay, West Ferry, was first for six bunches of early chrysanthemums, Mr. Geo. Scott taking second place. Flowers of hardy perennials in twelve bunches, distinct, were largely shown, but we did not consider the quality or arrangement quite up to high-water mark. Mr. Geo. Scott, Seathwood, was an easy first with nice bunches of gaillardias, pentstemons, montbrietias, statices, double gypsophila, and Aster acris. The second prize fell to Mr. J. S. Summers, Aschliff Gardens, Perth Road, Dundee.

It is often claimed that annuals are better shown at Dundee than anywhere, and this year's display was no variant to the rule. The flowers in Mr. G. Reid's first prize exhibit of eight vases were very fine, the collection including beautiful spikes of Statice Suworowi, clarkia, and godetia in double forms, together with fine Phlox Drummondi, sweet scabious, sweet sultans, and sweet peas. Mr. Thos. Butcher, Tay Lodge, West Ferry, took second honours, his flowers being good.

Some very nice border carnations were shown. In the class for twelve vases first honours were accorded to Mr. David Halley, Roycroft, Broughty Ferry. Linkman, Clement, Mandarin, Mrs. Geo. Hunter, Solfaterre, Aleppo, Mrs. Howard Green, and Crystal were all highly meritorious. Mr. J. S. Summers was second. In the gardeners' rose class Mr. John Ireland, Park Place, Brechin, staged the first prize twenty-four blooms, showing up-to-date varieties, Mr. John Simpson, Panmure Gardens, Carnoustie, taking second prize, his flowers being of good size and substance, and the third prize went to Mr. W. Lockhart, Rubie-law, Aberdeen.

Messrs. Adam and Craigmile, Ternilie, Rubieslaw, Aberdeen, received the leading prize for twenty-four H.P. or H.T. roses, showing a box of good, even flowers. Messrs. Croll came out premier with twenty-four teas and noisettes, there being nice flowers of Mrs. Foley Hobbs, Mdme. Constant Soupert, Miss Alice Rothschild, and Molly Sharman Crawford in their set; Messrs. Adam and Craigmile were second.

Mr. D. Smith, 10, Cleghorn Street, Dundee, obtained the first place in the amateurs' class for a table of cut flowers, using sweet peas, montbretia, and carnations to good effect. The second and third prizes were awarded respectively to Mr. A. R. Easton and Mr. Jas. L. Gray, Perth Road, Dundee. The numerous classes for florists' flowers, sweet peas, and border flowers in the amateurs' section were well filled, both as regards the number of entries and the quality of the exhibits.

FRUIT.

Fruits were largely shown, there being strong competition in the grape classes, and also in those for apples and soft fruits.

The chief class was for six bunches of grapes in not less than four varieties. There were four competitors, Mr. James Besiant, Castle Huntley, proving the champion. He had two splendid bunches of Muscat Hamburgh, a beautifully-finished bunch of Madresfield Court, and also Black Hamburgh and Muscat of Alexandria (two bunches). The pointing was as follows, the maximum obtainable being denoted by the bracketed figures: Black Hamburgh (9) 7½, Muscat of Alexandria (10) 7, 8, Muscat Hamburgh (9) 7½, 8, Madresfield Court (9) 8. Total points obtainable 56, points scored 46. The second prize was awarded to Mr. Geo. Mollison, gardener to J. H. Rigg, Esq., Cupar, who scored 40 out of a possible 56 points. Mr. Geo. Scott, gardener to A. S. Henderson, Esq., Seathwood, was third with 33 out of a possible 50 points. Mr. Besiant also obtained premier honours for four bunches, showing Madresfield Court, Black Hamburgh, Muscat Hamburgh, and Muscat of Alexandria, all good, well-finished bunches. Mr. Geo. Mollison was second with the same varieties. Mr. Wm. Nicholl, gardener to Wm. Henderson, Esq., West Park, was third. Mr. Besiant had the best two bunches of Black Hamburgh, and the first prize for two bunches of any other black variety went to Mr. Wm. Balfour, gardener to A. Moncur, Esq., Rockfield, who showed Lady Downes. Mr. Nicholl scored with two bunches of Muscat of Alexandria. Mr. Besiant again came foremost with two bunches of Black

A FINELY-GROWN COLLECTION OF CACTI AT DUNDEE.
For which the First Prize was awarded to Mr. Robert Birse, Carmichael Street, Dundee.

Alicante, and with a single bunch of Black Hamburgh. Mr. Wm. Balfour was first for a single bunch of Lady Downes, and the first prize for one bunch of Muscat of Alexandria was awarded to Mr. J. Bethel.

For a collection of twelve distinct kinds of apples, grown in the open, the winner was Mr. Geo. Scott, Seathwood, who had an even and otherwise excellent collection, Washington, Ecklinville, and Jas. Grieve being very good. Mr. Samuel Shields, Pitfour Castle, Glencarse, was second, his fruit being smaller, but of good quality; the third prize went to Mr. Wm. Benvie, gardener to Geo. Fairweather, Esq., Glencarse.

For three dishes of apples and three of pears, grown in an orchard house, Mr. G. Scott, Seathwood, took the lead. He had a really fine lot of fruit, his apples being of large size, as well as of good colour. Mr. Jas. Simpson, Panmuir, second. Mr. D. Milne, Linlathen, led for six dishes of hardy fruits, showing apples, plums, cherries, red currants, peaches, and nectarines. Mr. Jas. Birrell, Braid Castle, second.

VEGETABLES.

These filled a large space, and were, despite the drought that has prevailed through Scotland as well as England, of very fine quality; but then, as someone remarked as we were making our notes, Dundee show has never had poor vegetables.

The class for a collection of twelve kinds headed the section, and Mr. Wm. Harper, gardener to A. A. Allen, Esq., M.P., Tulliebelton, Perth, took the premier award with a splendid lot of produce. Mr. Jas. Kinnear, gardener to Mrs. Wienberg, Fernbrae, was second, only losing a point or two. Third prize was awarded Mr. Geo. Hendry, gardener to J. B. McNab, Esq., Keithlock. Mr. G. H. Young, Balmyle, Meigle, received first prize for a collection of twelve varieties of potatoes. It would be difficult to imagine tubers more symmetrical, smooth, and even than those shown in this collection.

In the amateurs' section, Mr. Alf. Drummond, Fowlis Wester, Crieff, showed a very good set of six kinds of vegetables, and was rewarded with first prize. Mr. John Hepburn, West Huntingtower, Perth, came second; and Mr. Wm. Goodall, Errol, third. Throughout the single dish classes the quality was high, and the competition keen.

NON-COMPETITIVE EXHIBITS.

There were numerous and attractive exhibits from the leading Scottish nurserymen, but the only English firm represented were Messrs. Sutton and Sons, Reading. It need hardly be said that their vegetables, melons, etc., were of remarkably high quality, and the tasteful manner in which the stand was decorated with flowers from their strains of seed reflected great credit upon those who arranged it.

Messrs. Dobbie and Co., Edinburgh, occupied a large space with gorgeous banks of collarette dahlias, roses, and sweet peas. Messrs. John Forbes, Lim., Hawick, were in great form with phloxes, pentstemons, carnations, and other florists' flowers. Four large tables were occupied by Messrs. Thyne and Son, 18, Union Street, Dundee, one being devoted to sweet peas, one to phloxes, and the others to choice annuals and to hardy border flowers. Messrs. Jas. Cocker and Sons, Aberdeen, put up choice roses and herbaceous flowers in variety, and Messrs. Laing and Mather, Kelso, made a good show of carnations. Gladioli were well shown by Messrs. Tillie, Whyte, and Co., Melbourne Place, Edinburgh. Roses played the leading part in Messrs. D. and W. Croll's exhibit, which contained also carnations, sweet peas, and hardy perennials. A large and elaborate exhibit was arranged by Messrs. W. P. Laird and Sinclair, Lim., Dundee. Floral designs of much artistic merit were a prominent feature, and there were also effective groups of decorative plants. A small rockery, furnished with alpines and dwarf shrubs, was built by Messrs. Jas. Laurie and Son, Blackness Nursery, Dundee, and Messrs. D. M'Omish, Crieff, put up a gay bank of phloxes. Messrs. Guthrie Bros., Priory Nursery, Ladybank, exhibited hardy border flowers and sweet peas, and Messrs. Harley and Sons, Dundee, staged some very artistic floral designs. Chrysanthemums, pentstemons, and carnations were the principal features of a very creditable exhibit from Messrs. Henderson and Sons, Dens Nurseries, Brechin.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE, August 26.

Present: Mr. E. Bowles (in the chair), Dr. Bateson, F.R.S., Messrs. Bennett-Poë, John Fraser, F.L.S., W. Hales, A.L.S., J. W. Odell, W. Cuthbertson, and A. Worsley.

Mr. Chittenden reported that the violet leaves sent by Mr. Druery were attacked by the Gall Midge, Cecidromyia violæ, and this had nothing to do with the laciniation of the leaf edges.

DOUBLE GLADOLI.—A letter from Col. Sanderman was read in connection with the alleged doubling of gladioli. As no specimen came with the letter the committee could not decide the point raised. Incidentally, Dr. Bateson remarked that if the fact were established it would be interesting as there were several families or orders, such, for example, as the labiatæ, that although having peloric forms do not show true doubling of the flower.

CAMPANULA DISEASE.—Mr. Edwards, of Sylfaen Gardens, Welshpool, sent leaves of Campanula persicifolia affected with Puccinia Campanulæ (Plowright and Berkley).

LATE BROOD OF SAWFLY.—Mr. Edwards sent a brood of the Sawfly (Gooseberry) caterpillar, Nematus ribesi. The committee thought this should be recorded owing to the very late period of hatching.

MATRICARIA SUAVEOLENS = M. DISCORDEA.—Mr. Odell showed this little composite from N.W. Middlesex. It is a recent immigrant to this country, and has been recorded by Mr. E. Bowles from Essex and Hertfordshire, and by Mr. J. Fraser from Aberdeen, and has become common in several other localities.

FASCIATED ALOYSIA CITRIODORA.—Mr. Odell showed stems of this plant fasciated, and having a very mixed phylotaxis, with the terminal parts showing the normal terete stem and normal phylotaxis. Dr. Bateson remarked that the condition was similar to that of the Crown Pea, Pisum umbellatum, where from a densely fasciated stem normal shoots were developed with flowers.

Dunfermline Flower Show.

AUGUST 29 and 30.

Dunfermline Horticultural Society is highly favoured in more ways than one. It benefits financially from the support of the Carnegie Dunfermline Trust. Its place of exhibition is the wondrously beautiful Pittencrieff Glen, which is a veritable fairyland of natural and majestic beauty, and its affairs are in the hands of a most capable and courteous secretary, Mr. John Hynd, who has the loyal support of an enthusiastic band of ready workers as members of committee.

PLANTS.

Mr. Peter Keir, Logie, received first prize for three stove and greenhouse plants, his set containing a fine dieffenbachia; second prize was awarded Mr. Robert Johnston, who had Fuchsia Corale in fine form. A fine pair of pyramid fuchsias was shown by Mr. William Taylor, Cotton, in the class for two flowering greenhouse plants, and obtained for him the first prize, the second prize going to Mr. Robert Johnston, Lassodie. Mr. Peter Laing showed two good palms, for which he received first prize, followed by Mr. James Mitchell, Broomhall. Mr. Robert Johnston led the way for four exotic ferns, the second prize going to Mr. Peter Laing. There were some grand adiantums and the finer varieties of Nephrolepis exaltata in this class. Mr. A. W. Taylor, Cotton, took first prize for two fuchsias with nicely trained and finely flowered specimens; Mr. Peter Smith, Bank View, Dunfermline, was second with well-flowered plants. Mr. Taylor also scored for a single specimen fuchsia, second prize being awarded Mr. Thomas Morrison, Grieve Street, Dunfermline. Mr. Morrison received chief award also for two zonal pelargoniums, and Mr. Robert Johnston was first with a single specimen plant.

CUT FLOWERS.

Roses were very well shown, the winning stand of twelve blooms, staged by Mr. John Bower, 59, Elgin Street, Dunfermline, containing choice blooms of some of the best exhibition varieties. Mr. F. Macrae, Fossaway, was placed second. There were eight entries in the class. Mr. Andrew Campbell, Doinbristle, had some fine spikes of gladioli in his winning six. Phloxes were another good class, the best six spikes coming from Mr. James Mitchell, Mr. Thomas Morrison being second, his flowers being very fine. Mr. H. Sharp, James Place, put up two vases of very good cactus dahlias, for which he received first prize, Mr. Robert Johnston winning for pompons.

Show pansies made a nice little class, Mr. H. Anderson, Appin Crescent, taking first prize; his flowers were shapely, clean, and the markings well defined. Mr. Charles Grey, Cowdenbeath, took the lead for fancies, Mr. Anderson taking second place. Carnations shown on boards brought Mr. J. Mitchell the first prize for a dozen blooms, some being of good size and fair quality. Sweet peas made a brave show, and some fine flowers were staged. Mr. H. Cummins, Blairhill, led the way for six vases, also taking special prize for the best vase of sweet peas in the show. Second prize went to Mr. Thomas Ritchie, Brankstan Grange. Mr. David Bayne, Middlebank, staged some grand spikes of pentstemons, winning first prize among seven strong entries. Antirrhinums, marigolds, asters, and other flowers were provided with a number of classes, in which entries were numerous, and quality good.

A great bank of herbaceous flowers along one side of the large marquee was composed of amateurs' exhibits, the prizes being offered for the best six bunches. The quality of the flowers was very high, and the exhibits were staged in capital manner. Mr. H. Cummings received first prize, showing splendid bunches of gaillardias, montbretias, Rudbeckia Golden Glow, Chrysanthemum maximum, Lilium tigrinum, and Campanula pyramidalis. Mr. James Mitchell was second prize-winner; Mr. G. Thompson received third prize. In the class for six bunches of hardy border flowers, shown with foliage or other decorations, the leading award was credited to Mr. James Mitchell. Mr. George Thomson was second.

Annuals were largely shown, and included some very effective subjects, such as godetias, clarkias, Linaria reticulata aurea purpurea, and Dimorphotheca aurantiaca. The amateurs' class for a display of sweet peas on a table 5ft. by 4ft. brought good flowers, tastefully arranged. Mr. H. Cummings, Blairhills, secured the first prize.

FRUIT.

Fruit was shown in considerable quantity, the competition, especially in the smaller classes, being very close. The leading class was for a collection of six varieties of dessert fruit, and in this the first prize was awarded to Mr. Finlay Macrae, Briglands, Fossaway. Black and white grapes were moderate-sized bunches, showing capital colour and finish. A fine dish of apples was also a strong feature of the exhibit. Mr. Hugh Cummings, Blairhill, Rumblingbridge, received second prize, showing nice peaches, grapes, plums, etc. Another class was for six dishes of outdoor fruits, and Mr. James Mitchell was the first prize-winner. He showed good plums, pears, apples, peaches, and nectarines. Mr. Hugh Cummings received second prize for a nice

lot of plums, gooseberries, cherries, etc. Mr. Peter Blair scored for two bunches of Black Hamburgh grapes, second prize going to Mr. David Howie, Dunimarle, and third to Mr. Charles Palmer, Alloa. Mr. John Waldie, Dollarbeg, received first prize for two bunches of any variety other than Black Hamburgh, showing two beautifully-finished bunches of Gros Maroc. Mr. James Mitchell won first prize for a bunch of grapes carrying the finest bloom, and for one bunch of any variety, showing Muscat of Alexandria.

VEGETABLES.

The quality in the vegetable section was very fine. The opening class was for a collection of eight varieties, and Mr. H. Cummings deserves congratulation on his success in winning the first prize with very fine products. Mr. James Mitchell, Broomhall, who was awarded the second prize, had good onions, White City potato, and excellent peas. Throughout the single dish classes the quality was high, and the competition keen.

NON-COMPETITIVE EXHIBITS.

Quite a feature of the show was a table of roses, exhibited by Mr. W. Ferguson, nurseryman, Dunfermline. He had some choice blooms in boxes, and tall bamboo stands filled with The Lyon, Lady Ashtown, and other effective and decorative varieties, the whole making a very attractive display. Mr. R. C. Ferguson, South Nurseries, Dunfermline, also showed roses of good quality arranged on tall columnar stands. The Lyon, Caroline Testout, Le Progrès, and La France were largely used, but other choice things were judiciously intermixed. Mr. J. Marshall, Brucefield Avenue, put up a table of miscellaneous plants, among which fuchsias and zonal pelargoniums played a leading part.

We cannot deal in detail with the many exhibits shown by cottagers and amateurs, but such things as begonias, foliage and flowering plants, fuchsias, petunias, etc., were splendidly exhibited, as also were bouquets and vases of cut flowers.

Dumfries and District Horticultural Society.

This society held its first annual show of flowers, fruit, and vegetables in the Drill Hall, Dumfries. The show was opened by the Duchess of Norfolk, and was highly successful, financially and from a horticultural point of view. The attendance was very large, and the classes were well filled with excellent produce. The leading honours fell to Mr. R. A. Grigor, Dalswinton Gardens, who secured the greatest number of points, and therefore won the silver challenge cup. Mr. Grigor also won the prize of a silver cup for the group of plants remarkable for taste in arrangement. Both gardeners and amateurs showed well, and sweet peas, herbaceous plants, and florist's flowers were excellent. Fruit was capital, and vegetables of high quality. In the section open to all the dinner table competition was very good, the first prize falling to W. J. Nicholson, Douievale. In the cut flower classes, Mr. J. M'Gill, Kirkconnell Gardens, won for flowers of herbaceous plants, and Mr. C. G. M. Murray, Cowhill Tower Gardens, for outdoor flowers.

In the vegetable classes Mr. R. A. Grigor led for the collection, but there was hardly anything between his exhibit and that of Mr. Murray. In the fruit classes grapes were very fine, and the collection was excellent. Mr. D. Campbell, Capenoch, led with the collection, and the winners for grapes comprised Mr. Campbell, Mr. Grigor, and Mr. J. Cluckie, Arbigland Gardens. The principal prizes in other classes were won by Mr. T. Carruthers, Cargenholm Gardens; Mr. W. Smith, Newtonairds Gardens; Mr. W. Scott, Drumpark Gardens; Mr. Grigor, Mr. Murray, Mr. D. Whitelaw, Locharbriggs; Mr. J. Henderson, Elmbank Gardens; Mr. J. Wilson, Summerville Gardens, etc., etc. Amateurs showed extensively and well, and trade exhibits were numerous and good.

Newcastle Flower Show.

The time-honoured society enjoying the title of the Durham, Northumberland, and Newcastle-on-Tyne Botanical and Horticultural Society, and the distinction of being the oldest society of its kind in the kingdom, opened its annual show in the Recreation Ground, Newcastle, on Tuesday, September 2, continuing for the two following days. It was a good show, although differing considerably from those of former years. For instance, stove and greenhouse plants were for many years a leading feature, but this year no big specimens were exhibited. On the other hand, vegetables produced a great display, and roses, sweet peas, and hardy flowers were very well shown. The new secretary, Mr. R. H. Newton, and Mr. Moffatt had the arrangements well in hand, and were both courteous and energetic in the discharge of their duties.

PLANTS.

The group class brought four entries, and very creditable they were. Mr. H. H. Hillier, Green Park Gardens, Darlington, was awarded first prize, he making good use of a number of brightly-coloured crotons, and a background of tall palms. Acalypha Sanderæ, Origanum hybridum, cattleyas, and cypripediums were among the chief flowering plants; and the groundwork of ferns and Caladium argyrites finished the group in an artistic manner. Messrs. Carnegie and Co., Lim., St. Mary's Place, Newcastle, were placed second, with an effective arrangement. Mr. J. Hetherington, gardener to C. T. Kendall, Esq., Preston House, North Shields, was awarded third prize.

Mr. J. Hetherington, Preston House, North Shields, had the best six ferns, showing three varieties of adiantums and three of crested nephrolepis. The other prizes went to Mr. T. Wilkinson, Croydon Road, Newcastle, and Mr. J. Forrester, Convalescent Home, Whitley Bay.

ROSES.

Messrs. Hugh Dickson, Lim., Royal Nurseries, Belfast, obtained premier honours for twenty-four roses, their stand containing nice blooms of Brilliant, King George V., and Hugh Dickson among crimsons; with Elsie Harkness, Reliance, Charle de Lapisse, and Lady Alice Stanley among the delicate shades. Messrs. Harkness and Sons, Bedale, came second, their blooms being of good quality, but just a trifle damaged by a violent thunderstorm. Messrs. Hugh Dickson, Lim., again led the way with twelve blooms, showing White Killarney, The Lyon, Mrs. John Laing, Coronation, Cardinal, etc. The second prize was awarded to the Rev. R. R. Hedley, Kirkwelpington Vicarage, Newcastle.

The first prize for six vases of decorative roses was awarded to Messrs. Hugh Dickson, Lim.; and the second to Messrs. G. Gibson and Co., Leeming Bar.

CUT FLOWERS.

The contributions to the class for twelve bunches of hardy herbaceous plants made a very striking display. Messrs. Harkness and Sons, Bedale, took the lead with beautiful bunches of Papaver orientalis Mrs. Perry, Gladiolus Thermidor, Lilium tigrinum splendens, Gaillardia Mrs. McKellar, Helianthus Soleil d'Or, and H. multiflorus maximus, Lupinus polyphyllus roseus, and—the best vases of all—Verbascum New Departure and V. North Riding. Messrs. G. Gibson and Co., were second, showing good gladioli, montbretias, and liliums. Mr. T. W. Daniel, Dunelm Nursery, Bedale, third. In a small amateurs' class for three vases of flowers of hardy perennials there were five entries, and Mr. Fred Finlay, Layton, Albrough, Darlington, was first with bunches of montbretia, Lilium longiflorum, and Gladiolus Brenchleyensis. Mr. J. W. Smith, Wensleydale Sanatorium, Aysgarth, Yorks, second, and Mr. Henry Cole, Guide Post, Choppington, third.

For twelve bunches of sweet peas, Mr. Joseph Shaw, gardener to O. W. Hedley, Esq., Dilston Hall, Corbridge, was first. His flowers were of good varieties, bright, and clean, and on long stems. Mr. Geo. Finlay, gardener to Mrs. Maynard Proud, East Layton Hall, Darlington, was a good second. For three bunches of this year's novelties the first prize was awarded to Mr. Shaw, who staged James Boose, Mrs. E. Cowdy, and Agricola. Mr. Edward Keith, Wallington Gardens, Cambo, was second, and Mr. Samuel Russell third.

The best six vases of sweet peas in the amateurs' section were those staged by Miss E. L. J. Humble, Ettringham House, Stocksfield-on-Tyne, Mr. J. Feuster, Greenside Ryton, being placed second. Mr. Wm. Watson, Coquet House, Blucher Colliery, put up the first prize set of three bunches.

Mr. Cecil L. Cawkell, gardener to F. Straker, Esq., Angerton Gardens, Morpeth, was the winner for a display of perpetual-flowering carnations. The flowers were shown in a bold style; Mr. Joseph Shaw was second. The prizes for six vases of border carnations brought quite good flowers for so late in the season. The Rev. W. McLean Brown, Hawthorn Road, Gosforth, Newcastle, received premier award, showing nice flowers of Daffodil, Bob Acres, Father O'Flynn, and other good varieties. Mr. Robert Elliott, gardener to J. R. Scott, Esq., Harden Benton, second.

TABLE DECORATIONS.

There were thirteen entries in the class for table decorations, which gave the judges some difficulty in assigning them their relative positions. Eventually the leading award was made in favour of the table arranged by Mr. W. H. Lambert, gardener to the Right Hon. Earl Grey, Howick Gardens, Lesbury. Mr. G. F. Hallett, gardener to Sir R. J. Graham, Bart., Netherley Gardens, Carlisle, was second. For a shower bouquet. Messrs. Reillys won first prize with a tasteful arrangement of lælias, odontoglossums, and lily of the valley. Miss E. Reilly, Clayton Park Square, received second prize.

FRUIT.

There was only one entry for six dishes of fruit, the exhibitor being Mr. J. C. McPherson, gardener to the Right Hon. Earl of Londesborough, Londesborough Park, Market Weighton, and he deservedly received the prize. He had two bunches each of Madresfield Court, and Muscat of Alexandria grapes, a dish of very highly-coloured Clapp's Favourite pear, Pineapple nectarines, Violette Hative peaches, and Jordan's Seedling melon. Mr. McPherson led for four bunches of grapes, showing excellent bunches of the same varieties as in his collection. The second prize was awarded to Mr. J. R. Gardiner, gardener to Lady Cowell, Clifton Castle, Bedale. Mr. Wm. Mark, gardener to Miss Muschamp, Farnley Hill, Corbridge, took third prize. Mr. McPherson repeated his success with two bunches of white grapes, showing Muscat of Alexandria in fine form. Second prize was awarded to Mr. Wm. Mark.

Mr. J. R. Gardiner scored for two bunches of black grapes, staging Gros Colmar with big berries, and well-finished. The second prize was won by Mr. Edward Keith, Wallington Gardens, Cambo, with Gros Maroc in fine form. Mr. T. H. Bolton, gardener to the Right Hon. the Earl of Devon, Powderham Castle, Exeter, showed six dishes of dessert apples, for which first prize was awarded. The fruits were shapely, of good size, and well coloured. Mr. Bolton also scored for six dishes of culinary apples. He had remarkably fine examples of some of the best cooking varieties. Mr. G. Shotton, gardener to Mrs. Lowe, Prudhoe Hall, Prudhoe-on-Tyne, was second, his dish of Emperor Alexander being very fine. Mr. Geo. Finlay, East Layton Hall, Darlington, was third.

VEGETABLES.

These were well shown, but mostly in single dish classes. Leeks were a notable feature, and were of a quality equalling that seen at the keenest North Country competitions. The class for three leeks had ten

entries, and Mr. John Wear, Felton Mills, Felton, took first prize, his leeks being splendid examples, measuring about fourteen inches of blanched stem, and approaching two inches in diameter. Mr. Thompson Smith, Fourstones Village, received second prize, these again being remarkably good. The third prize was taken by Mr. Jas. Fewster, Greenside, Ryton. Mr. T. H. Bolton, Powderham Castle Gardens, took first prize for parsnips, Mr. Edward Keith winning for peas, and Mr. W. Bean, Riverdale, Ebchester, for celery. Mr. T. H. Bolton showed six grand Ailsa Craig onions, with which he secured first prize, he also winning for runner beans.

The amateurs' collection of vegetables brought first prize to Mr. John Wear, Felton Mills, Felton, who showed good leeks, celery, parsnips, a pair of large cauliflowers, and excellent cabbages and onions. Mr. Robert Shield, Waterside Cottage, Swalwell, took second prize.

NON-COMPETITIVE.

The bulk of the non-competitive exhibits were staged in one large marquee, and a very bright and interesting display was the result. Across one end Messrs. Kent and Brydon, Darlington, arranged a terrace garden with retaining wall planted with rock plants. A grass plot, surrounded by a paved walk, was backed by a border of hardy flowers, and on either side were groups of bamboos, acers, and other foliage plants with beds of liliums and spiræas. Mr. C. H. Taudevin, Cheltenham, staged a capital group of perpetual carnations, embracing a number of the choicest varieties staged in a tasteful manner. Hardy flowers were put up by Messrs. Dickson's, Lim., Chester, various liliums and gladioli being bright and striking features of the exhibit.

A large stand of choice vegetables with epergnes of melons and dishes of tomatoes came from Messrs. E. Webb and Sons, Wordsley, Stourbridge. Sweet peas, godetias, asters, and other flowers were tastefully interspersed among the vegetables, and displayed on a series of arches, extending the whole length of the stand.

Ornamental shrubs, vines, and ivies were arranged in a group with Hydrangea paniculata and hardy fuchsias by Messrs. Michie and Co., Alnwick. Alpine plants of choice character were nicely arranged among stones and fibre by Mr. Wm. Lawrenson, Yarm-on-Tees, who also showed bunches of good border perennials. There were nicely-flowered plants of Stokesia cyanea, Papaver alpinum, several good campanulas, and brilliant alpine mimulus on the stand, together with androsaces, saxifrages, and a few ferns. Messrs. Stuart and Mein, Kelso, had a large mound of sweet peas, arranged on the ground with other groups of herbaceous flowers, some ferns and dwarf euonymus and golden privet.

A gorgeous bank of phloxes was staged by Messrs. Chas. Irvine and Sons, Jedburgh, Scotland, among the most telling varieties being Countess of Minto, W. S. Oliver, Snowdrift, and Mrs. Roughhead. Mr. W. Lawrenson, Yarm, had a good group of perpetual carnations, the white Snowstorm being shown in capital form.

Pentstemons were a great feature of the exhibit brought by Messrs. John Forbes, Lim., Hawick. The firm also showed a fine lot of border carnations, and a collection of phloxes and other perennials.

Messrs. Geo. Fairbairn and Sons, English Street, Carlisle, showed dahlias, embracing cactus, pompon, collarette, and pæony-flowered varieties.

Messrs. Furney and Co., Newcastle, contributed a group of gladioli, which embraced a good variety of colours, and were of pleasing form. Messrs. Harkness and Sons, Bedale, staged a collection of phloxes, verbascums (very fine), gladioli, pæony dahlias, and a variety of useful border perennials. Another good group of hardy flowers came from Messrs. G. Gibson and Co., late flowers of single pyrethrums.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of THE GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of THE GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in THE GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

DAFFODILS FOR GRASS CULTURE.—W. F. H., Surrey: I am desirous of planting daffodils in a portion of our pleasure grounds where there is no occasion for mowing the grass until the leaves of the daffodils have turned yellow or died down. Being desirous of producing a display that will possess interest as well as attractiveness, and extend over a considerable period, I should prefer to plant small breadths of a number of kinds.—Your proposal is an exceedingly good one, and in full accordance with our views on the subject. The practice of planting moderate breadths of several kinds in comparatively small gardens will give much more pleasure and interest than will huge breadths of three or four kinds. The following varieties succeed in the grass, and will afford the diversity in form and colour in the time of flowering that you desire: Albicans, Agnes Barr, Barri conspicuus, C. J. Backhouse, Emperor, Empress, Golden Spur, Grandis, Henry Irving, John Bain, Minnie Hume, Mrs. Langtry, Mrs. Walter Ware, Poeticus ornatus, P. R. Barr, Sir Watkin, Stella superba, and Victoria. The bulbs of the foregoing will range from 5s. to 7s. 6d. per 100. We suggest that you form a colony of Madame de Graaff with one or two dozen bulbs; it will afford an immense amount of pleasure, and the bulbs are decidedly cheap. The sooner the bulbs are planted the better, and, as the ground has been well moistened with the rains, we suggest that you proceed with the planting at once.

NITRIFICATION IN SOILS.—E. P., Lancashire: It has been found, as the result of careful investigation, that nitrification takes place with a greater degree of rapidity in a comparatively heavy soil than in a light one, in which sand greatly preponderates. This is attributed to the larger percentage of lime in the heavy soil, but the lack of humus in the sandy soil also greatly influences the result in favour of the more substantial medium.

THE LOGANBERRY.—T. A., Herts: For some years I have held an appointment abroad, which, from its exacting nature, gave me but little time for gardening. On retiring a short time since, I returned to England, and settled down with a comparatively large garden, in which I hope to be able to grow fruits and vegetables as well as flowers. Since my return we have bought both fresh and bottled fruit of the loganberry, which was quite unknown in English gardens previous to my going abroad. I am anxious to grow it, and shall be glad to learn something about the fruit and its cultural requirements.—The loganberry is a fruit that you should have no difficulty in cultivating successfully. It was raised in Canada by Judge Logan from a cross effected between the blackberry and the raspberry. You are acquainted with the colour and flavour of the fruits, and you will have noticed that they are rather firmer and more acid than are raspberries, and therefore preferable for culinary purposes. They are especially useful for bottling. The loganberry grows under much the same conditions as the raspberry, but, owing to the length of its wide-spreading growths, requires more room for development. Briefly stated, the soil should be prepared as for raspberries, and the plants should be put out in the autumn, one-year-old plants being the best. Where there is more than one row on the same plot the rows should be eight feet apart. For supporting the growths a trellis six feet high should be provided, and this should be formed with stout posts and strong wires stretched between them at distances of twelve inches apart, commencing from the strand of wire stretched along the top of the posts. The plants should be eight feet apart in the rows, and seven or eight shoots be allowed to each, the others being removed at a quite early stage. The canes remaining for fruiting in the following year should be loosely tied to the wires or other support as growth progresses, and immediately after the fruiting period the old canes should be cut away to ensure the full exposure of the new canes to the light and air.

SUNDIALS.—J. H., Lincolnshire: I am interested in sundials, and perhaps you can tell me when the first sundial was invented.—We have devoted considerable time to the study of the science of gnomonics, but, as in the case of others who have given attention to sundials, we have not been able to find evidence that will enable us to say when sundials were first made. In the Bible we find ample evidence of the existence of a horologe, and of its use for measuring time. The most ancient of the known sundials are of Grecian origin, and, writing in 343 B.C., Herodotus states that the Greeks obtained their knowledge of the sundials from the Babylonians. The Romans, in their turn, acquired their knowledge of sundials from the Greeks, and obtained considerable fame as makers of dials, while the wealthy citizens added them freely to their gardens for purposes of ornament and utility. The earliest of the dials known in this country were of Saxon origin.

AUBRIETIAS FOR BEDDING.—T. O., Dorset: Being very partial to aubrietias, I have endeavoured for some years past to use them rather freely for carpeting beds, in which tulips and daffodils are planted, but the results have not been satisfactory. My difficulty has been to maintain good stocks of plants owing to the losses that occur among the plants lifted from the beds in April or early in May. It will be a great help to me if you can give me such advice as will enable me to prevent the plants dying during the summer months.—We appreciate the difficulty with which you have had to contend, and we suggest that you change your practice. Instead of breaking up the plants when you remove them from the flower beds in May and then planting them in nursery beds, we advise you to commence the propagation of stock quite early in March. To enable you to do this you must devote some portion of the reserve ground or kitchen garden to them, and the best time for planting the stock plants is early in October. In March lift small portions of the aubrietias with a few roots attached and put them about eight inches apart in rows, with fifteen-inch spaces between them to allow room for the free use of the hoe. By the autumn you will have stocky

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

plants six or seven inches in diameter, that can be transferred to the beds with but little check. This method requires more space for the preparation of the stock, but it effects a considerable saving in time, and is altogether more satisfactory than the usual method of procedure.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

R. B.—1, Nepeta Mussini; 2, Kniphofia Burchelli; 3, Macowani; 4, Lythrum virgata.

S. S. (Oxford).—1, Tradescantia virginica; 2, Thalictrum minus adiantifolium; 3, Linaria repens alba.

SUBSCRIBER.—1, Pteris biaurita; 2, Trichomanes radicans Andrewsi; 3, Blechnum polypodioides; 4, Gymnogramma chrysophyllum.

H. SMITH.—1, Bignonia venusta; 2, Echites rubro-venosa; 3, Allamanda violacea; 4, Strobolanthes Dyerianus; 5, Vitis Voinieriana.

K. S.—1, Olearia Haasti; 2, Galtonia candicans; 3, specimen much shrivelled, and all that can be said with reference to it is that it is one of the herbaceous phloxes.

YOUNG GARDENER. — 1, Pentstemon Hartwegi, which is now so generally grown in gardens under the name of Newbury Gem; 2, Parnassia palustris, or the Grass of Parnassus; 3, Salvia virgata nemorosa; 4, Santolina chamæcyparissus.

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, GARDENERS' MAGAZINE, as advised in the notice at the head of "Answers to Correspondents."

H. J. B.—1, Wyedale; 2, Coe's Golden Drop; 3, Comte d'Althan's; 4, Bradley's King; 5, Monarch.

S. R. H.—1, Doyenne d'Alencon; 2, Triomphe de Vienne; 3, Ne Plus Meuris; 4, Forelle; 5, Grosse Calebasse.

W. S.—1, Allington Pippin; 2, Bielo Borodawka; 3, send after Christmas when the fruits have attained their proper colour; 4, Summer Golden Pippin.

A. B.—1, Princess of Wales; 2, Thames Bank, and 3, Lady Palmerston peaches; 4, Spenser; 5, Milton; and 6, Victoria nectarines. The crab is John Downie.

J. H.—Your apple is Byford Wonder, and you may, as you suggest, plant it in the orchard. The tree has a spreading habit, bears freely, and the fruit keeps until March.

INQUIRER.—The fruit is too much decayed to admit of identification, but it may be Clapp's Favourite. Pears for naming should always be sent before they are fully ripe, as when they have reached that stage at the time of sending they invariably decay before they reach us.

The Carter Spinach.—Where this vegetable is in demand, I can recommend the popular variety "The Carter" worthy of a trial, if it has not already been given one. I have grown it for several seasons, both for summer and winter use. So far it has not once failed. It produces very large, deep green leaves, with plenty of substance, without any trace of coarseness, and does not run to seed nearly so quickly as most varieties of spinach are apt to do during dry weather. I have grown it for three seasons side by side with a prickly spinach for winter use; and I find it gives double the return, standing wet and frost equally as well—this, too, on cold, stiff ground.—T. B. F.

GARDENING ENGAGEMENT.

Mr. James Smith, a well-known Aberdeen gardener, has been appointed to the post of superintendent of Kirkton Cemetery, Fraserburgh, Aberdeenshire. A native of Lumphanan, Mr. Smith served his apprenticeship at Brodie Castle, Forres. He was seven years head gardener to Mr. James Murray, ex-M.P. for East Aberdeenshire, Glenburnie Park, Aberdeen, and for two years with Lieut.-Colonel W. E. Gordon, V.C., Caskieben, Aberdeenshire.

A thunderstorm occurred at 10 a.m. on Friday, 29th.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

MONDAY, September 8.—United Horticultural Benefit and Provident Society, Committee Meeting.
National Chrysanthemum Society's Floral Committee Meeting at 3 p.m., Essex Hall, Strand.
TUESDAY, September 9.—Royal Horticultural Society; committees meet at 12 o'clock; lecture at 3 p.m. on "Stem Vegetables: Their Dietetic Values, and Various Ways of Cooking Them," by Mr. C. Hermann Senn; Scientific Committee at 4 o'clock.
National Dahlia Society, Crystal Palace; two days.
WEDNESDAY, September 10.—Royal Caledonian Horticultural Society; two days.
THURSDAY, September 11.—National Rose Society's Autumn Show at the Royal Horticultural Hall: two days.
Messrs. Dickson and Robinson's Vegetable Show at Manchester; two days.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Floral Transformation.

If we could possibly resuscitate a few of our garden-loving great-grandfathers and convey them to some of our up-to-date flower shows, say at Chelsea or Holland Park, we are sure that one of their greatest surprises, and even puzzles, would be the changes effected in recent times in the flowers with which they were familiar in the old days. Many of these are now so utterly transformed that they would be unrecognisable, while a good number of the exhibits are practically, so to speak, subsequent creations, and hence entire novelties. Take as a type of the latter class the tuberous begonias. In their time, if species with tuberous roots existed in this country at all, they possessed so little decorative value as to be merely found in botanical collections, the noteworthy begonias then being those possessing foliar beauty of the Rex type, whose flowers were regarded as quite secondary adjuncts of little or no value. The progenitors of the present brilliant crowd of flowering begonias, which had blossoms of quite moderate size, were not known in British gardens. They were introduced later, and when the possibility of hybridising distinct species was recognised. As a result, in course of time, larger and larger blooms, and brighter and more varied colours appeared among the hybrid offspring, until eventually we came to possess the magnificent flowers rivalling even the rose in delicacy and variety of tints, make, and, what is even more, in freedom of blooming. Again, what would they think of our roses? True, unlike the begonias we have mentioned were unknown, there were fine roses—ramblers, standard, and bush—but there were none to be compared with the latest and most brilliant and floriferous types of each kind which now decorate our gardens with such profusion and such brilliancy of colour that an exhibition of the best is positively dazzling. With the dahlia also another puzzle would present itself. This formed, it is true, a recognised and important "cult" even in the old times referred to, and had then reached practically a state of perfection in the way of regularity of form and diversity of colour. But what of the types? There was then only one, the almost spherical ball of curved and closely-packed petals which fell into two classes, the full-sized show dahlia and the more or less diminutive pompon. These two had their representative societies and their competitive exhibitions on a very large scale, but eventually, like other flowers whose capacities of variation and further development seem to have reached their climax, the dahlia fell into the background. Then, by what was practically an accident, the Mexican Juarez form found its way into this country, and at once revolutionised the dahlia cult. In lieu of the compact short-petalled form of the time of our ancestors, the long attenuate-petalled or cactus type was encouraged and developed, and in time produced as many brilliant colours as the compact form had done, and the varieties formed a great and important section. Encouraged by this capacity of transformation, raisers, instead of rejecting as ineligibles or "rogues" all seedlings of variant types, as they did in the old times, thus throwing away the chances which Nature offered them, grew them on, with the result that nowadays we have the great loose, broad-petalled flowers of the pæony type, and the new so-called collarette forms, with a circle of vari-coloured slender florets in the centre, which, though still, as a rule, in the imperfect stage, promise great things in the future. At a recent meeting of the Royal Horticultural Society a charming exhibit, showing the possibilities of the old-fashioned scabious in the shape of a large number of charming novelties, would have formed another surprise, and recently the old-fashioned snapdragon (antirrhinum) has made a marked move in the direction of increased size, which promises much to entitle it to rank, as someone recently said, as "one of the flowers of the future." Many other flowers might be cited in this same connection. The sweet pea may be cited as a special case, having been elevated from a simple ornament of a cottager's garden to be the worthy objective of many societies, and a "cult" in itself. The marvellous chrysanthemum might also be referred to, but would need much space. On the other hand, our assumed visitors would miss many of their old friends. Where now is the balsam, which seems to have been incapable of vieing with its many competitors in the varietal way, and is now rarely seen? Our old friend the fuchsia still holds its ground to a certain extent, but seems to have proved its incapacity to go beyond certain lines, the very form of its flower appearing to preclude any such new breaks as we see in the begonias, dahlias, and others flowers which have come to the fore in recent years. In addition to the class of floral development of which we have referred, there would also be the many new introductions with which our forefathers would necessarily be unacquainted, but we have already said enough to demonstrate how much more fortunate than they is the garden lover of these days as regards the immensely greater floral wealth at his disposal, due to the long-continued work of the selective cultivator, plus that of the traveller in far-distant countries, who has, in many cases, furnished him with the raw material.

Proposed Registration of Orchid Hybrids.—Now that so many orchid lovers are raising hybrids it becomes increasingly difficult to keep a clear record of the work done, so that duplication of names may be avoided. The R.H.S. Orchid Committee finds this an ever-present difficulty, and not seldom a hybrid granted an Award is found, by the next meeting, to have been wrongly named, the publication of the parentage in the Press having brought to light the fact that a hybrid of similar parentage already existed. The society's records only concern themselves with plants certificated or granted Awards of Merit. To meet the difficulty referred to the following motion was unanimously adopted by the Orchid Committee at Vincent Square, on September 9, and passed as a recommendation to the Council of the Royal Horticultural Society: "In view of the necessity of securing the earliest possible records of new hybrids, and to supplement the list of plants which have received awards, the Orchid Committee recommend that a new record, to be called the Hybrid Orchid Register, be established, and that orchid raisers and growers be asked to bring their new plants which are flowering for the first time, even although they may not be sufficiently developed to enter for awards, and to enter the name, parentage, and name of raiser (or exhibitor) of the plant on a registration form, to go before the committee. After testing to prove that the name is in order, it shall be entered on the society's Hybrid Orchid Register, and, once recorded, the name must be recognised for all crosses of similar parentage when subsequently shown, unless valid reason can be produced to prevent it."

Purchase of a Seed Business.—We are informed that Messrs. Sutton, of Reading, have purchased from Messrs. J. Veitch and Sons, Lim., the seed business carried on at Chelsea for the past sixty years, and this department, with the stocks of seeds and horticultural sundries, will be transferred to Messrs. Sutton and Sons as from October 1, 1913. Messrs. Sutton have also purchased from Messrs. Veitch and Sons, Lim., the principal portion of the seed grounds at Langley, near Slough, adjoining the Great Western Railway, but Messrs. Veitch's nursery trade will still be carried on for some time to come at Chelsea, Langley, and Feltham, until Sir Harry Veitch retires altogether from business.

Dahlia Trials at Duffryn.—The extensive dahlia trials that are being carried out by Reginald Cory, Esq., in his gardens at Duffryn are proving highly successful, and fully merit the interest they have created. The trials were instituted by Mr. Cory for the purpose of determining the merits of the several sections for garden decoration, and include nearly one thousand varieties. Mr. Cory invited the Royal Horticultural Society and the National Dahlia Society to co-operate with him in selecting the varieties of special value for the garden, and a committee, consisting of equal numbers of the members of the two societies, was appointed to visit Duffryn. The members of the committee were Messrs. J. Green, H. J. Jones, J. B. Riding, A. Turner, J. T. West, and F. G. Treseder, and they devoted the whole of two days (September 4 and 5) to the performance of their somewhat arduous but exceedingly pleasant task, in examining the 7,000 or 8,000 plants, and recording their decisions on the merits of the varieties. The majority of the plants are growing in

threes, while the others are in sixes, and the beds contain from twenty to thirty plants each. Every member of the trade in this country sent plants for the trial, and a number were contributed by Continental growers. Needless to say, that under the care of Mr. Cobb, the head gardener at Duffryn, the plants are in the best possible condition, and the result surprised not a little the members of the committee.

Gardens of the City of London. — Notwithstanding the immense value of land, and the rapidity with which every square foot is covered with bricks and mortar when the builder is allowed scope for his activity, there are many sylvan spots within the boundaries of the City of London that are equally remarkable for their interest and beauty. Hence the series of illustrated descriptions of the "Gardens of the City" that are now being given in the "City Press" will be especially welcome to those who are in any way associated with the City, or concerned with the rural aspects of large towns. The gardens that have been dealt with are those of Fen Court, off Fenchurch Street (August 23), St. Paul's Cathedral (August 30), and St. Botolph, Aldgate (September 6).

Women and Gardeners' Associations.—The question whether women should be admitted to the membership of gardeners' associations still remains unanswered to the satisfaction of all concerned. At the annual meeting of the Gardeners' Mutual Improvement Associations in affiliation with the Royal Horticultural Society, the question was discussed without any conclusion being arrived at. On the 18th inst. the Watford branch of the British Gardeners' Association will devote its meeting on that date to a consideration of the question, "Should Women Gardeners be Admitted to Membership of the British Gardeners' Association?" We should imagine that a solution might be found in five minutes if those interested would present some good arguments for or against the admission of women, instead of indulging in innumerable repetitions of "I don't think." The time and place of the Watford meeting is not stated, but the branch secretary, Mr. S. Hartley, The Lodge, Glenthorne, Harrow Weald, will afford information upon these two points to any of our readers who may desire it.

R.H.S. Bulb Show, 1914.—A special exhibition of forced spring-flowering bulbs will be held by the Royal Horticultural Society on March 10 and 11, 1914, with the object of demonstrating the varieties best suited for gentle forcing. There are six classes for hyacinths grown under the usual conditions, with liberal prizes, which have been presented by the General Bulb Growers' Society at Haarlem. Several classes have, as usual, been provided for hyacinths, tulips, and narcissi grown in moss, fibre, or similar material.

North British Railway Station Gardens.—For the best-kept stations and gardens on the system of the North British Railway, the directors arranged for four classes of prizes, i.e., £4, £3, £2, and £1. In the first class 20 are placed; these, with the names of the station masters being: Abbeytown, Mr. Douglas; Armadale, Mr. Nairn; Auchendinny, Mr. Aitken; Broomieknowe, Mr. Wright; Cairneyhill, Mr. Davidson; Cauldcots, Mr. Dickson; Cupar, Mr. Stewart; Drumchapel, Mr. Hunter; Eskbridge, Mr. Barn; Hawthornden, Mr. Murray; Helensburgh, Mr. Stevenson; Jedfoot Bridge, Mr. Grieve; Kilbagie, Mr. Purves; Melrose, Mr. Beveridge; Newcastleton, Mr. Bell; St. Monans, Mr. Swinton; Singer, Mr. Ramsay; Slamannan, Mr. Ferguson; Strathblane, Mr. Cuthbertson; Summerston, Mr. Murdoch.

The Ghent Horticultural Congress.—The International Horticultural Congress, held at Ghent from August 7 to 11, is recalled to our minds by the receipt of a substantial volume, entitled "Preliminary Reports, Vol. I." It gives a list of the various subjects dealt with, and the names of the Organising Committee. The papers are mainly in French, although a few are in English or Flemish, and the scope of them is a wide one, for the subjects are many and diverse. Among the authors we notice Messrs. F. Chittenden, Cyril Harding, Arthur de Smet, Ad. Buyssens, H. Jadin, the Abbé Torfs, Camille Vouloir, Louis Dop Curé, and Louis Lorette.

Croydon Gardeners' Excursion.—This year the members of the Croydon Gardeners' Association visited, on the occasion of their annual excursion, the gardens of Frencham Hill, near Farnham, the residence of C. Hay Walker, Esq., one of the vice-presidents of the society. The members, to the number of about sixty, found much to interest them in the extensive flower and kitchen gardens and in the well-filled glass structures, and were much impressed by the excellence of the work that is being accomplished by the joint efforts of Mr. Walker and his able gardener, Mr. Rowson.

Sale at Coombe Wood Nursery.—The first portion of the stock of trees and shrubs at Messrs. J. Veitch and Sons' Coombe Wood Nursery, Kingston, will be sold by auction by Messrs. Protheroe and Morris on October 13 and four following days. The stock includes a portion of the collection of new Chinese plants, of which some are not yet in commerce. The negotiations for the sale of Messrs. Veitch's seed business and the freehold land at Langley were carried out by Messrs. Protheroe and Morris.

State Forestry in Argyllshire.—The Inkerleven Estate, in Argyllshire, is being rapidly developed in accordance with the most approved methods of afforestation as a State forest, and the success achieved fully justify the course of procedure that has been followed. Last year 29,900 trees, chiefly the common spruce and the Sitka spruce, were planted in Compartment I., 4,300 trees in Compartment II., 6,500 trees in Compartment III. Fifty-five acres were planted with 123,400 trees, and 20,000 trees were planted to replace failures in Compartment IV., and 123 acres were planted with 261,700 trees in Compartment V. It has been difficult to keep the rabbits under owing to cairns within the enclosures, and during the heavy snowfalls in January and February hares were able to enter the enclosures and do some amount of damage.

An International Registry of New Plants.—The International Professional Horticultural Union has made arrangements for establishing a register of new plants on an international basis, which will be under the direction of Mr. Van Lennep, the general secretary. The names of the new plants will be entered on the official list with their classification, description, and origin, and it will thus be possible to maintain the right of priority of the raisers and introducers of novelties. The raisers or introducers must send a list of their novelties to Mr. Van Lennep, 15, Molenstraat, La Haye, Holland, with a fee of two francs for each variety. The names of the plants will be entered on the list in the order of their being received, and it may therefore be of importance to make the entries on as early a date as practicable. Raisers are requested to make the descriptions as exact as possible, and to take note of the fact that they are not to exceed three lines. It is suggested that descriptions be given in English, French, and German, and when this is done the description in each language may be equal to three lines.

A Productive Cherry Tree.—In several of the cantons of Switzerland cherries have been extensively planted, and in some of the orchards the trees have attained to an immense size, and bear heavy crops of fruit. In some instances the trees are planted alongside the public roads, where they bear freely, and the fruit reaches maturity without suffering from the depredation of boys, large or small. This year one of the cherry trees at Faourg, near Avenche, in the canton of Vaud, has borne two tons of fruit, which, it is stated, took three men fifteen days to gather. This particular tree bears small red fruits, which are utilised in the production of kirsch, and it is anticipated that of this liqueur 200 litres will be obtained, representing at five francs a litre a sum of about £40.

Lucknow Government Horticultural Gardens.—In the recently-issued report of a year's work in the Lucknow Gardens, Mr. H. J. Davies, the superintendent, shows how varied are the duties that fall to his lot. No fewer than 24,926 plants and cuttings, and 7,964 packets of seeds were distributed during the year to Government institutions and by sale. It is interesting to learn that Mr. Davies grows numerous varieties of peaches, strawberries, pears, grapes, oranges, figs, and roses; and to learn that strawberries are extensively cultivated in and around Lucknow; and that until lately the young plants and new varieties were supplied from the Government gardens at nominal rates. We read of a successful flower and vegetable show in February, and a chrysanthemum show in December. The education of a gardener is a difficult problem at Lucknow as at home; and Mr. Davies, who is an old Kewite, writes that "the unwillingness of young men to join the Choudhray class is to be regretted, as the inducements held out are very much better than obtain in offices and many other professions. The chief objection would-be students have to joining the class is that they have to do the actual work of a 'mali' for a portion of each day, and carry out with their own hands operations which entail a certain amount of manual exertion. Students have an idea that only class work is needed or expected of them, and often resign when they find out that such is not the case. It is the practical side of their work that they most need to fit them to teach others when they finish their course, and the gardens insist that this shall be the first consideration in their training."

Turin International Exhibition, 1911.—The Italian authorities responsible for the organisation of this exhibition have just issued a diploma, most effectively and artistically designed in colours, for presentation to those who took part in the work. In size it is twenty-four by twenty inches, and has been sent to each member of the British Royal Commission. We are sure that the members of the horticultural section of the Commission will highly appreciate such a beautiful souvenir of their connection with the Turin Exhibition. A similar presentation was made on the occasion of the Brussels Universal Exhibition of 1910.

EDINBURGH AUTUMN EXHIBITION.

Edinburgh Show, which may be said to conclude the summer shows of Britain, has for many years been an exhibition on extensive lines of all that is best in British horticulture, providing what may almost be termed a grand finale to the summer's programme of horticultural events. The exhibition, which was held in Waverley Market on Wednesday and Thursday, September 10 and 11, was no less worthy of the society's reputation than have been the best of its predecessors. Indeed, it was from end to end a magnificent show. Fruit, as usual, was a great feature, and vegetables were also splendid; while, so far as flowers were concerned, there was an abundance of all sorts, hardy, exotic, natural species, or garden varieties of choicest quality. The trade exhibits were of great extent, and of varied character, adding immensely to the interest of the show.

FIRST PRIZE TABLE OF DESSERT FRUIT AT EDINBURGH SHOW,
Exhibited by Mr. Wm. Galloway, gardener to the Earl of Wemyss, Gosford.

PLANTS.

These are not a great feature, but nevertheless those shown were of considerable merit. Mr. Jas. McNeill, gardener to Major Thorburn. Craigerne, Peebles, exhibited four stove or greenhouse plants in flower, winning first prize. A blue hydrangea, ixora, statice, and fuchsia were the subjects shown. Second prize went to Mr. Geo. McKinna, gardener to Sir Robt. Usher, Bart., Norton, Ratho, who had a big, freely flowered swainsonia, a fine zonal pelargonium, and a statice and Lilium longiflorum. Mr. A. McMillan, gardener to the Right Hon. the Earl of Home, Douglas Castle, received third prize. Mr. A. Findlay, gardener to A. Drybrough, Esq., Gogar Park, scored for three cypripediums, showing a fine C. Lord Derby carrying several blooms. Mr. A. Jeffs, gardener to R. Hindle, Esq., 17, Blacket Place, Edinburgh, scored for one orchid, showing a good example of Odontoglossum grande. Two dracænas brought first prize to Mr. John Thorn, Carlowrie, the variety Duchess of Portland carrying rich Monifieth, Dundee, taking second prize with a good plant of Phœnix Roebelini.

Ferns were beautifully shown, Mr. J. McNeill, gardener to Major Thorburn, Craigerne, Peebles, scoring for four exotic kinds, which included Asplenium nidus, Goniophlebium subauriculatum, and two other good plants. Second prize was awarded Mr. A. McMillan, Castle Douglas, who made good use of a crested nephrolepis, and a very good golden gymnogramma. Third prize went to Mr. A. Findlay. Four large British ferns formed another interesting class, the winner being Mr. Jas. Turnbull, gardener to Alex. Cowan, Esq., Penicuick. Lastrea cristata augustida was very fine indeed, and a big osmunda was good. Mr. Alex. Johnstone, Hay Lodge, Trinity, had third prize, but we could find no second prize card. Mr. Thos. Hirmston, Gogar, led the way for four adiantums, Mr. A. Findlay and Mr. A. McMillan securing the other awards.

British ferns in six-inch pots were, as usual, extremely good. Mr. J. C. Brown, 25, Waterloo Place, Edinburgh, received first prize for a capital set of nine plants. Asplenium trichomanes incisum, Athyrium f. f. acrocladon, and Lomaria alpina were very nice. Lastræa pseudo-mas crispa cristata augustata, a fine fern, was also well shown. Second prize went to Mr. J. Turnbull, Penicuick, who had Adiantum imbricatum and a nice set of other small-growing ferns. Third prize was taken by Mr. A Black, School House, East Calder. Mr. J. C. Brown, Waterloo Place, also won first for six scolopendriums, showing a set of beautifully frilled and crested forms.

FRUIT.

This section is always a very important feature of the Edinburgh show, and, although there were in some classes slightly less than the average entry, the display was grand, and some splendid fruit was staged. The opening class was for a decorated table of dessert fruit, size ten feet by four and a-half feet. Mr. Wm. Galloway, gardener to the Earl of Wemyss, Gosford, received first prize. He had four bunches of grapes, the Muscat of Alexandria being particularly fine, as also was Madresfield Court. Durondeau and Souv. du Congrès pears were good, and a large Universal melon occupied one end of the table. Other dishes were Jefferson plum, Lord Napier nectarine, and Royal George peach, besides apples and apricots. White lilies, pink carnations, and sprays of Francoa ramosa were the floral decorations used. The collection of twelve dishes of dessert fruit had four entries, and some splendid fruit was shown. Mr. Wm. Hunter, gardener to the Marquis of Tweeddale, Yester House, received first prize, and he showed both black and white grapes of good quality and some good peaches, nectarines, Brown Turkey figs, Jefferson plums, and Emperor Alexander apples. He also had large pears and a Superlative melon. The floral decorations were montbretias and francoa. Second prize went to Mr. D. Kidd, gardener to Lord

Elphinstone, Carberry Towers, whose fruit was also very good, but he could have improved his floral decorations. Mr. Jas. Small, gardener to John Graeme Thomson, Esq., Norwood, Alloa, was third, his Muscat Hamburgh and Madresfield Court grapes being supported by a pineapple, melon, and some fine pears, apples, and peaches.

GRAPES.

The fame of Edinburgh Show for the remarkable quality of its grapes has once again been well maintained. Some grand exhibits were staged, and the competition was very keen. The opening class was for six bunches, not less than four varieties, and three competitors staged in this class. Mr. Samuel Gordon, gardener to Sir H. E. Maxwell, Bart., Monreith, Wigtownshire, was declared winner. He had a long, shapely bunch of Madresfield Court, a very heavy bunch of Mrs. Pince, and another of Alnwick Seedling. Black Hamburgh was good, and so was Muscat of Alexandria, the sixth bunch being a duplicate of Black Hamburgh. Trails of ampelopsis and vases of pinks and Scabiosa caucasica set off the fruit, and the whole exhibit was a triumph of skilful cultivation. Mr. D. Halliday, gardener to W. Mackay, Esq., Ascog, Bute, received second prize, the running being very close. Mrs. Pince, although good, was slightly below the winner's magnificent bunch, Alicante was well finished, and Appley Towers, although not an over large bunch, was very fine. Mrs. Pearson was the only white bunch shown, and it was a good one. The decorations were superior to the winner's, Caladium argyrites, and small orchids being tastefully arranged. Mr. Robert Glen, gardener to R. M. Donaldson, Esq., Blairvaddick Row, Dumbarton, was awarded third prize, his grapes being big, shapely bunches, but not well finished in comparison with the other exhibitors.

Mr. J. Buchanan, gardener to the Earl of Mar and Kellie, Alloa Park, secured first prize for two bunches of Muscat of Alexandria grapes, showing medium-sized bunches, which were beautifully finished; second prize was taken by Mr. Wm. Hunter, gardener to the Marquis of Tweeddale, Yester House. Mr. John Middleton, gardener to William Forbes, Esq., Callander House, Falkirk, led for two bunches of Black Hamburgh, his bunches being broad-shouldered, and richly-coloured. His follower was Mr. John M. Stewart, gardener to J. Neilson, Esq., of Mollance, Castle Douglas; and third prize went to Mr. Samuel Gordon, gardener to Sir H. E. Maxwell, Bart., Monreith, Wigtownshire. Mr. Buchanan had a beautiful single bunch of Muscat of Alexandria, which was awarded first prize; second place being taken by Mr. Wm. Hunter; and third by Mr. G. Anderson, gardener to Right Hon. A. J. Balfour, M.P., Whittinghame. Mr. Middleton led for a bunch of Black Hamburgh in a strong class of ten entries; second prize going to Mr. Robt. Glen, gardener to R. M. Donaldson, Esq., Blairvaddick Row, Dumbarton; Mr. Samuel Gordon being third prize winner.

A bunch of Alicante won first prize for Mr. Jas. McNeill, gardener to Major Thorburn, Peebles, Mr. Samuel Gordon coming second, third prize going to Mr. D. Halliday, gardener to W. Mackay, Esq., Ascog, Bute. Mr. Samuel Gordon scored for a bunch of Alnwick Seedling, his bunch being weighty and of good quality. Second prize was awarded Mr. Jas. Duff, gardener to C. L. Gordon, Esq., Threave House, Castle Douglas; Mr. Angus Robb, gardener to M. Nairn, Esq., Dysart House, Fife, being third. For a bunch of Gros Colmar the first prize went to Mr. Jas. Wood, gardener to Claud A. Hamilton, Esq., Larbert; Mr. J. Shields, gardener to Sir John W. King, Bart., Carstairs House, Carstairs, being second. Mr. D. Kidd, gardener to Lord Elphinstone, Carberry Towers, led for a bunch of Lady Downes, Mr. Wm. Kirk taking second prize. Appley Towers was well shown by Mr. John Middleton, who led in this class, and Mr. Robt. Glen scored with Madresfield Court. Other single-bunch classes were for any other black variety, won by Mr. D. Kidd with a big bunch of Gros Maroc; and any white variety, for which the first prize was awarded Mr. Samuel Gordon, whilst for the bunch of black grapes carrying the finest bloom, Mr. Jas. Small, gardener to John Graeme Thomson, Esq., Norwood, Alloa, led with Appley Towers in perfect form and condition.

APPLES

These were shown in quantity, although, owing to most of the classes being confined to Scottish-grown fruit, they did not make so extensive a display as we have sometimes seen here. Mr. E. W. Caddick, Caradoc Fruit Farm, Hereford, brought a fine lot of fruit for his collection of eighteen varieties. Lady Sudeley was nicely coloured, Lord Derby and Stirling Castle were large, and throughout the set there were good examples of well-known varieties. Mr. R. M. Whiting, Credenhill, Hereford, was second prize-winner, showing somewhat smaller but quite good fruit. Third prize was secured by Mr. Thos. Smith, gardener to the Marquis of Ripon, Coombe Court, Surrey. Mr. Robert Currie, gardener to the Rev. G. H. Davinport, Hereford, won for twelve dishes with Worcester Pearmain, The Queen, Peasgood's Nonsuch, and others. Mr. Thos. Smith, Coombe Court, Surrey, took second prize, The Queen and Worcester Pearmain being nicely coloured. Third prize was awarded Mr. E. W. Caddick. Mr. Robt. Currie led for six dishes with some capital fruit, Mr. R. M. Whiting, Hereford, being placed second, Mr. Thos. Smith bringing up the rear.

For twelve varieties of Scottish outdoor growth, the winner was Mr. Jas. Duff, gardener to C. L. Gordon, Esq., Threave House, Castle Douglas. Duchess of Oldenburg, Gascoigne's Scarlet, Worcester Pearmain, and Lady Sudeley carried as much colour as is found in English-grown fruit. Second prize was secured by Mr. R. G. Sinclair, Congalton Gardens, Drem; and third prize went to Mr. Wm. Laing, Gateside, Fife. Four dishes of apples from under glass brought three entries, the first prize being taken by Mr. D. Nicoll, gardener to Miss Bell, Rossie, Forgandenny. He had Emperor Alexander, Wealthy, Gascoigne's Scarlet, and James Grieve, all very large, richly coloured, well-finished fruit. Mr. J. E. Hathaway, gardener to John Bremand, Esq., Baldersby Park, Thirsk, was second; and third prize went to Mr. J. M. Stewart, gardener to J. Neilson, Esq., of Mollance, Castle Douglas. Single dish classes were so numerous that we were obliged to withhold details, but we must say quality was better than we had expected to find it.

PEARS.

The principal class for pears was for twelve dishes, four on each. First prize was secured by Mr. J. E. Hathaway, Thirsk. The fruits were not exceptionally large, but they were clean, even samples of some of our best varieties. Second prize went to Mr. R. M. Whiting, Credenhill, Hereford, who also showed some very good fruit. Mr. Wm. Galloway, gardener to the Earl of Wemyss, Gosford, led for six dishes of pears grown in Scotland, and among his collection were nice fruits of Williams' Bon Chretien, Durondeau, and Clapp's Favourite. Second prize went to Mr. Ronald Johnson, gardener to H. Hope, Esq., Luffness; Mr. R. G. Sinclair, Congalton Gardens, Drem, coming third. For four dishes of orchard-house pears, Mr. Andrew Harvey, gardener to Miss Hamilton, Rozelle, took the leading prize. His fruits of Marguerite Marillat were beautiful specimens, Durondeau, Doyenne du Comice, and Pitmaston Duchess being the other dishes. Mr. J. E. Hathaway had Beurre Fouqueray in place of Marguerite Marillat, the other dishes being of the same varieties as the winner's. This exhibit secured second prize; Mr. D. Kidd, Carberry Towers, being third prize-winner.

CUT FLOWERS.

The class for cut flowers from the open brought keen competition. Mr. A. Dickson, gardener to M. G. Thorburn, Esq., Glenarmiston, Innerleithen, received first prize for a grand lot of flowers. There were montbretias, statices, lobelias, and rudbeckias, all of rich colours, and clean, well-grown flowers; in fact, the whole collection was very fine. Mr. Adam Brydon, Tweedmouth, Innerleithen, took second prize, also showing excellent gladioli, charming montbretias, and good liliums, with a choice variety of other subjects. Mr. Wm. Young, gardener to Mrs. Fleming Hamilton, Kirkcowan, was placed third out of six excellent exhibits. Mr. Wm. Young took leading place for six bunches of herbaceous flowers. He had Lilium auratum, Lobelia Firefly, Anemone japonica alba, and some good montbretias and helianthus. Second prize went to Mr. J. Bertram, Peebles. His Dracocephalum speciosum, Veronica subsessilis, lobelia, and Echinops ritro were grand bunches. Mr. W. G. Pirie, Dalhousie Castle, received third prize, his set including an attractive bicoloured lupin.

Annuals were charming. Mr. J. Cochrane, Langlee Gardens, Galashiels, showed twelve beautiful vases of good things, including tall scabious, salmon-coloured Phlox Drummondi, Arctotis grandis, rich purple and gold salpiglossis, and other pretty flowers. Second prize was awarded Mr. R. McAndie, Musselburgh, whose Cosmos, Shirley poppies, and larkspurs were fine. Mr. J. Sword took third prize. Mr. Jas. Paul, Drumbeg, Killearn, received first prize for a good exhibit of cactus dahlias in six bunches. Mary Purrier was brilliant, with Comedy and Jupiter, striped, and Snowdon, pure white. Second prize was won by Mr. Hugh Rutherford, gardener to W. Duncan, Esq., Brechin. For twelve cactus dahlias on boards, the leading award went in favour of Mr. Hugh Rutherford, whose flowers were of good size and very finely twisted petals. Harold Peerman, a clear yellow, was a very useful flower on the stand. Mr. Jas. Paul, Drumbeg, Killearn, took second prize, the third going to Mr. David Barbour, Johnshill, Lochwinnoch.

Mr. John Bertram, Peebles, had the lead for six hollyhocks, being followed by Mr. W. Brow, Gogar Burn. Mr. J. Stewart, jun., showed splendid spikes of gladioli, winning first prize for twelve spikes. Carmelite, Dryade, Aristophane, and Corsaire were the names of some useful things on the stand. Second prize was awarded Mr. J. C. Fordy, Castleford Castle, Warkworth, Newcastle, whose spikes were not so well furnished as the winner's. Mr. Adam Brydon, Innerleithen, was placed third. Mr. W. T. Landreth, Coldstream, was first for six spikes, second prize going to Mr. J. Stewart, jun., Whins, Alloa, Mr. A. Brydon again receiving third prize.

In the open class for twenty-four spikes of gladioli, Messrs. G. Mair and Sons, Prestwick, led the way with some capital flowers, perfect in form, and of considerable length. Second prize was secured by Messrs. Alex. Campbell and Sons, Cove Gardens, Gourock, who also showed very fine flowers.

ROSES.

In a special open class for thirty-six roses, Messrs. Adam and Craigmile, Fernielea Nurseries, Aberdeen, took first prize. Marquise de Sinety, Gloire de Chedane, Guinoisseau, Lieutenant Chaure, and Jonkheer J. L. Mock were good. Mr. W. Ferguson, Dunfermline, took second prize in this class. He had a richly-coloured Lyon, a brilliant G. C. Waud, and a good Mrs. Theodore Roosevelt. Twelve vases of roses, open to nurserymen, also brought some fine flowers, the winning lot being staged by Mr. W. Ferguson. La Tosca was good, and Edu Meyer and General McArthur were very pretty. Second prize was awarded Messrs. J. Fairley and Co., Cairneyhill, Fife. Messrs. D. and W. Croll, Dundee, received first prize for eighteen tea roses, their stand containing shapely blooms of Mrs. Edward Mawley, Georges Nabonnand, Mamas Cochet, and other good varieties. Mr. R. C. Ferguson led the way for twelve red roses, showing Hugh Dickson, second prize going to Messrs. D. and W. Croll, who used John Stuart Mill, and third prize to Mr. W. Ferguson, Hugh Dickson again being the variety. Mr. R. C. Ferguson's dozen blooms

(Continued on page 700.)

SWEET CHERRIES IN SCOTTISH GARDENS.

Of the various kinds of hardy fruits so successfully cultivated in northern parts, it is probably correct to assume that the cherries, more particularly the sweet or dessert varieties thereof, give greater trouble, and cause more anxiety as the ripening stage approaches, than is the case with any other purely outside-grown fruit. It is very seldom that one meets with a fruitful standard tree, one that, except for its blossom in spring, would be useless owing to the almost impossible task of preserving the ripening fruit from the attention of birds, which generally make an attack thereon at the first slight sign of colouring. With trees trained against a wall the matter complained of is considerably simplified, but protection is necessary, and in heavily-wooded districts the greatest care is essential, by way of affixing the protecting nets, to prevent access of the depredators, which during the fruit season seem to visit most gardens in great numbers, though at other times they may not appear unduly numerous or aggressive.

Position or Aspect.

One important feature relative to the cherry is that it will thrive as a wall-trained tree on any aspect except that of due north, and even that may with advantage be utilised for the culture of such hardy and free-bearing varieties as Bigarreau Napoleon, Black Tartarian, and May Duke, which thus form a successional supply to others having warmer and more favoured positions. A wall facing the south-east is, however, the best for the great majority of the varieties included in the genus, where they succeed in growth, fruitfulness, and longevity better than when a due south aspect is made use of. In planting it is advisable to confine the cherries to one quarter of the garden, which, if walled around, presents at least three different aspects, and a longer succession of ripe fruit may accordingly be obtained than would be possible from one only. By concentration, as far as this is possible, more effective protection, both from frosts when the bloom is expanding, or later from birds, is more easily carried out.

Suitable Soils.

The cherry will grow in most fairly rich and well-worked garden soils, but prefers one that is inclined to be of brittle or sandy nature, resting upon a substratum of chalk or gravel. It is abundantly proved that a soil highly impregnated with lime in some form is necessary, a fact borne out by the successful results attending the culture of the trees in some parts of Kent, where but a thin layer of soil overlies the chalk beds, into which the roots very soon penetrate, and luxuriant growth, lasting health, and fruitfulness ensues. It is at once obvious that in many parts of the country the cost of chalk is so great as to render its use on a large scale prohibitive. Lime, either in a fresh state, or as obtained in the abolition process of old buildings, is often used as a substitute for mixing with the soil in which the trees are to be planted. With the former a considerable time should be allowed to elapse between the application of lime and the planting of the trees, or injury may possibly accrue to the tender rootlets. Lime rubbish as cast aside by builders' workmen requires careful inspection to rid it of all fragments of wood and stone, and should also be reduced to the requisite degree of fineness.

Providing the natural soil of the place is of fair quality, the excavation of a space from two to four feet in diameter, circular or half-circular in form, according to position and the style of tree favoured—standard or trained for wall—and nearly fill this with prepared soil, which may consist of the most suitable loam obtainable, to which is added sufficient coarse sand, road grit, and lime to render it porous. J. DAY.

(To be continued.)

BASKETS OF ROSES.

Two descriptions of baskets are now in vogue for presenting roses to public notice at exhibitions, and both are so admirably adapted to the special purposes for which they are required as to fully merit the most liberal encouragement being given them, whether the shows be wholly devoted to roses or to cut flowers of various kinds. The basket best known, and the most generally used, is that which is included in schedules for the purpose of giving exhibitors an opportunity of displaying their taste and skill in the arrangement of cut flowers. This basket is usually characterised by lightness, and is more or less fanciful in design, and when there is a keen competition, as so frequently happens, the basket class is one of the most attractive in the section devoted to the decorative use of roses and other cut flowers. All such baskets are not tastefully filled, but at the majority of exhibitions the average is high, and when one or two arrangements are distinctly poor they serve to bring into greater prominence the distinctive characteristics of those which represent taste of a high order.

A TASTEFUL ARRANGEMENT OF IRISH ELEGANCE ROSE
In a plain, round basket at the National Rose Society's Exhibition.

The other basket is quite different in design to that with which visitors to exhibitions have been so long accustomed. It has no handle or ornamentation, is made of brown wickerwork, and is inexpensive. It is simply a shallow skep, with, in the case of the baskets used at the exhibitions of the National Rose Society, a diameter of 14in. Those who have not seen such baskets at exhibitions filled with fragrant and attractively coloured flowers might be excused were they, on first seeing the empty baskets, declare them to be wholly unfit for staging roses. The baskets are not of themselves objects of great beauty, but they are neat and quiet in colouring, and in no way come into competition with the flowers arranged in them.

The advantages of these baskets, which were first introduced by the National Rose Society, include their suitability for both exhibition and decorative roses, their lightness, and small cost. They can be the most strongly recommended for blooms of the varieties grown for decorations, but at the smaller shows, where the exhibitors do not devote special attention to roses, they may be adapted for the display of the exhibition varieties also. We, however, suggest that baskets of roses should be included in schedules as supplementary to, rather than instead of, boxes of roses, and that they be fully utilised for blooms of one variety. The basket with a diameter of fourteen inches will accommodate eighteen blooms without overcrowding, and, according to our experience, the best results are obtained when the number of flowers to be arranged in a basket is stated in the schedule. When no limit is placed upon the number it often happens that there is much overcrowding, and a consequent denudation of the garden of flowers. For the arrangement of the blooms tubes filled with water are used, and made secure with a packing of light material, which is all the better with a surfacing of green moss. The tops of the tubes should not be more than two inches above the level of the basket.

The arrangement of Irish Elegance herewith illustrated was shown by Mr. J. Mattock at the metropolitan exhibition of the National Rose Society, and is a good example of exhibiting roses in plain round baskets. G.

THE GARDEN OF WESTERN CHINA.

It is probably possible to obtain more lasting enjoyment from a love of beautiful flowers than from anything else in this world. The coming of summer, which brings so much joy to us, really centres round the renewal of life, the unfolding of buds, and opening of flowers; without this summer would, indeed, be barren. Wander through any first-rate garden, however, particularly some of the older gardens of England, and you will notice that many, perhaps most, of the plants are not natives of the country; they have been introduced from abroad—lilies from South Africa, calceolarias from South America, magnolias from Japan, and a host of others—and have now found a permanent place amongst lovers of gardens. But a very great number have been only quite recently introduced, and are as yet altogether unknown to the public. It is the profession of a few men, a very few amongst whom I number myself, to collect new and striking plants which will prove hardy in England; the collection of hothouse orchids, for many years an extremely profitable undertaking, is being, to some extent, eclipsed by this new departure, the introduction of hardy novelties as a business undertaking.

The European Alps were the earliest hunting ground, and English rockeries have long been enriched by gentians, saxifrages, primulas, and so on from those regions.

Then followed plants from the Himalaya, Kashmir, Sikkim, and other parts, the last chiefly associated with the name of the late Sir Joseph Hooker; the name of Fortune will always be remembered in connection with Chinese plants, and the Rockies and Andes have also contributed their share.

However, it soon became evident that the vast mountainous region of Western China and Tibet, so long closed to travellers, and not by any means widely open to-day, was the real garden of the world for hardy plants, and the immense undertaking of systematically exploring these grim mountains has started. Already rich finds have been made, though only the fringe of the country has been touched, and years of work lie ahead. But a start has been made, Tibet has been put under tribute. The greatest finds are at present known only to a few, but we may look forward to the day when, thoroughly acclimatised and improved by cultivation, they will adorn many a famous garden. The hardy plant hunter in Tibet leads an active, adventurous life, full of incident, and sometimes of danger.

He is away from the company of his fellow white men for months at a time, climbing mountains in all weathers; wild tribes are his constant companions, wild animals cross his path, storms and floods and avalanches are his daily portion. But he would not exchange places with an Emperor when he returns to civilisation and sees the wonderful flowers he has risked so much to obtain flourishing in the beautiful surroundings of an old English garden.

I am going to tell of some of the plants I brought back from Tibet in 1911, and particularly of the blue poppies—meconopsis—prince of hardy plants.

We are now up on the great Mekong-Yangtze watershed, a terrific range of bare rocky peaks, rising, in some instances, over 20,000 feet above sea level, though the rivers are here barely thirty miles apart as the crow flies.

The forest has long since died away, and the last straggling dwarf trees lie 1,000 feet below us. Soon the shrub belt, too, is passed, the scrub rhododendron dwindles to dwarf species, rising only a few inches above the grund, and finally dies out; now there is only a short tuft, starred with purple Primula bella, a lovely dwarf species, and brilliant yellow tufts of Saxifraga negroglandulosa amongst the rocks.

Bleak and bare the precipices tower above us, and vast screes, with huge angular lumps of rock, litter the slopes; a biting wind comes screaming over the passes; wraiths of cloud form out of nothing, disappear, and reform around the limestone towers, and still we climb on.

Now we are over 17,000 feet above sea level, but, save in the deep sheltered corries, there is no snow here from June to September. Grim and forbidding, the grey masses of rock lie in confusion, silent memorials of the glaciers which long ago moulded these valleys.

And among these boulders, scattered here and there, we shall find the Cambridge-blue Poppy (Meconopsis speciosa), remote, unfriendly, alone. Well do I remember the first plant I saw—it was a poor specimen, for it had opened early; it was only the end of June, a bitter grey day, with scudding clouds which obscured the sun and toned down the overwhelming brilliance of the light.

But in July I returned, and found scores of these wonderful blue poppies peeping up from the dark cavities of the scree or sheltering beneath scattered rocks. Each flower was an inch or an inch and a-half across, of a bright Cambridge blue, with a mass of golden stamens in the centre. The plant rarely exceeded eighteen inches in height, but eight or ten flowers, borne singly on short pedicels, springing up parallel to the main axis, was no uncommon sight. Imagine these glowing gems in that cold, grey desert of rock up at the extreme limit of flowering plants towards the everlasting snows of Tibet.

In autumn, when the wind was ripping to ribbons the blasted vegetation, and the snow was creeping down, I returned to the haunt of the blue poppy, and harvested seed.

But there are many other plants on this range which are worthy of the collector's notice. At 16,000 feet we shall find the blue Primula brevifolia, and dwarf Monkshood, Aconitum Hookeri, and on limestone rocks there are sure to be masses of the brilliant crimson Primula dryadifolia, all three recently introduced into England.

On the alpine grassland, at about 15,000 feet, is the dwarf poppy, Meconopsis rudis, of a purplish colour, and still lower down in the alpine meadow region, the pink Androsace spinulifera, with dense heads of flowers.

Then there are the gentians, most wonderful of all Gentiana ornata, with its long trumpet-shaped corollas of deep blue, and saxifrages too numerous to recount; the yellow Lilium lophophorum, with its single nodding flowers, and the quaint Labiate, Phlomis rotata, an excellent ornamental plant for rock gardens.

On the limestone cliffs again we shall find masses of the delicate Isopyrum grandiflorum, covered with pale violet flowers, though this has proved singularly difficult to grow in England, and is not likely to be on the market for some time. It comes from 13,000 feet, so should be quite hardy, but the seeds do not readily germinate. In the forests, at 12,000 feet, we shall find numerous shade-loving primulas, such as the blue-flowered P. sonchifolia, and the pink P. septemloba, Pyrola atropurpurea, and other plants.

But we must not fail to explore the mountains further west, where the rainfall is much greater, and quite a different set of flowers occurs. In the dense forests of fir and rhododendron trees occurs the magnificent Lilium giganteum, each plant 8ft. or 10ft. high, bearing aloft a dozen or more large white trumpet flowers. Higher up, in the rain-drenched alpine meadows at 13,000ft., we shall find sheets of the sulphur-yellow poppy, Meconopsis pseudo-integrifolia, and the yellow Primula sikkimensis; and in marshy places the still more remarkable P. Franchetti, with its single large and irregular flowers of a rich purple. In other places the meadows are pink with a very striking lily, Fritillaria Soulei, or white with Anemone japonica.

Finally, out on the rain-swept grassland plateau itself, we may come across the Oxford-blue poppy, a new species of Meconopsis which has been named M. Wardi, after the writer. In this article I have mentioned but a few of the most recently introduced and most handsome hardy alpines from the garden of Asia. Hundreds of others, many of them new to science, and the vast majority new to horticulture, have been brought back during the last few years, though it will be some time before the great gardening public can get hold of them, so great is the demand and so small the supply. But those who are keen on hardy plants and rock gardens cannot do better than turn their attention to these new plants, which are being secured from the remote mountain ranges of Asia.

F. KINGDON WARD, B.A., F.R.G.S.

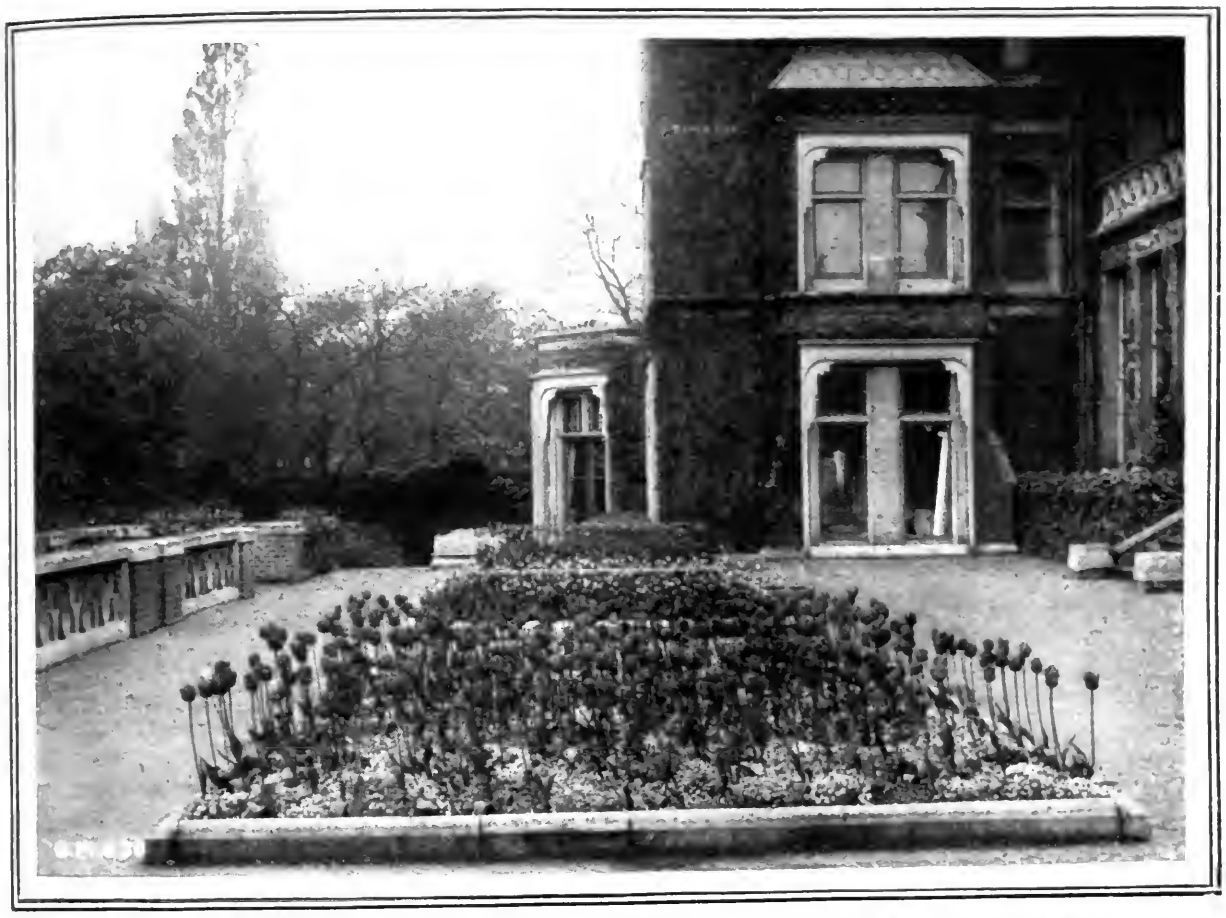
SCILLA BIFOLIA.

Scilla bifolia is not so frequently met with in gardens as Scilla sibirica, and although it does not rival the latter in the intense blue of its flowers, it is nevertheless a most welcome and pretty subject in the spring season. It is chiefly valuable on account of its early flowering, and from the general resemblance the blooms bear to some forms of Chionodóxa Lucilæ. The flowers are of a rich dark purple-blue, carried on short slender stalks, some eight or more individual flowers being loosely arranged on the slender spikes, which attain a height of six to eight inches, and are in flower at practically the same time as the snowdrops. Scilla bifolia is a pretty subject to naturalise in short grass, at the edge of woodlands or in the less formal-kept parts of the garden, while it also forms a welcome addition to the rock garden, especially when grouped so that when in flower it appears as a cataract of blue spreading itself over some gentle slope. Scilla bifolia præcox is a stronger, earlier-flowering form than the type, and the variety taurica is a larger edition. The individual flowers are about an inch across, while each spike carries double as many flowers as the type.

THOMAS SMITH.

DARWIN TULIPS.

Tulips are the most brilliant of spring-flowering bulbs; they are also moderate in price, and their popularity is probably as much attributed to the latter fact as to the intrinsic merit of the flowers. While the single and double Dutch tulips are pre-eminently adapted for pot culture, and to supply cut flowers and material for indoor decoration during early spring, the Darwin tulip is the kind par excellence for outdoor decoration; its flowering season marks, as it were, the dawn of summer. When the harsh winds and uncertain weather that usually characterise our winters and springs become abated, it is then that the Darwin tulip brings its wealth of colour, with the promise of the year full upon us.



DARWIN TULIPS ON THE TERRACE AT COOMBE COURT.
The beautiful Pride of Haarlem in the foreground.

There is scarcely another spring-flowering bulb to rival it in parterre planting, for it is there that the stately, noble, and dignified character of the plants gain fullest expression. It is also vigorous enough to combat with the greedy roots of shrubs, and no more pleasing picture can be conceived than by employing Darwin tulips—either mixed or to colour—as a groundwork among the shrubs. Again, in many gardens it is the custom to devote certain borders exclusively to the display of spring flowers, and for such an arrangement the Darwin tulip is indispensable, both on account of its height and colour; and when accompanied by a groundwork of some close-growing plant, the combinations into which it is capable of entering are practically inexhaustible.

The character of the Darwin tulips may be described as cosmopolitan, for it appeals to persons of widely different tastes and without distinction. In its season it can be fully enjoyed by the million, for every public garden and park of repute grows Darwin tulips in ever-increasing quantity. Their cultural requirements are simple and well defined. Fully-matured and ripened bulbs are the best to start with, and in order to produce the highest quality of flowers the ground should be deeply trenched before planting, adding a liberal dressing of old decayed farm manure. Planting is carried out from the end of August till November, early planting being advisable with these as with other bulbs, for after the latter date they begin to lose in vigour from undue exposure to the air.

When bulbs can be allowed to mature and ripen naturally, Darwin tulips will increase and give a display indefinitely. The best natural soil to produce this result is a calcareous loam, or limestone and chalky soils. Darwin tulips give excellent results, and they are practically immune from disease, this being always most noticeable where little or no manure was given at the time of planting. When these tulips are extensively employed in bedding arrangements, it is usually necessary to remove them when partly ripened, in order to make way for the summer-flowering subjects. In these circumstances the bulbs naturally suffer, for, even if the work is expedited, some considerable drying up of the roots follows, and the bulbs do not attain the degree of perfection they otherwise would. In this case the bulbs should be heeled in until the foliage is quite ripe, then lifted and sorted towards the end of July, replanting almost immediately in the reserve garden, when, if unmolested for a season, good average bulbs will be produced the following year. Even supposing these bulbs are not required for the parterre again, they are invaluable for supplying cut flowers.

Varieties of Darwin tulips are exceedingly numerous, and the gradation of colour fairly wide. There are, of course, no yellows such as occur among the Single Dutch and Cottage tulips. The lightest tints are found in La Candeur, Painted Lady, and Margaret, these being almost white or a faint blush only when fully expanded. The darkest shades, in some instances almost black, are represented by The Sultan, Faust, and La Tulipe Noire, the former being the dwarfest, and the last-named the tallest grower. Light chocolate or heliotrope shade is represented by Dream and Rev. Ewbank; while the glowing crimson-scarlet of the pelargonium is reflected in Mr. Farncombe Sanders, Minister Tak van Poortvliet, Glow, Europe, Ariadne, William Pitt, and Isis.

Clara Butt is a perfect flower of a matchless shade of salmon-pink. Rose colours are faultlessly represented in Psyche and Queen Wilhelmina; while an attractive combination of rose, with the edges of the segments feathered pale blush, is found in Mdme. Krelage and Baronne de la Tonnaye, both varieties being faultless in flower and habit. Salmon King is one of the brightest shades of all; the stems are stiff and erect, while the price places it within easy reach of all. Pride of Haarlem is always a satisfactory and reliable tulip; the flowers are of the largest size, rich carmine in colour, and the stems about thirty inches in height, while it flowers seven days in advance of Mr. Farncombe Sanders. Queen of Roses is the only variety I have found unsatisfactory, and this because the stems do not appear able to carry the flowers, which bend over, and form a blemish in a concerted bedding scheme.

AN EFFECTIVE BED OF TULIP MADAME KRELAGE.
One of the most beautiful of the Darwin varieties.

THOS. SMITH.

OLEARIA NITIDA.

This promises to be one of the best of the New Zealand daisy-bushes, and to rival the most attractive species when it attains a large size. Olearia nitida was introduced into this country from New Zealand in 1886. Though an extremely handsome shrub, it is, curiously enough, but rarely met with in gardens at the present time, although such species as O. Haasti, O. stellulata (often misnamed O. Gunni, which is quite a distinct species), and O. macrodonta, are fairly common. In its native country Olearia nitida is said to reach the size of a small tree, and to grow at an elevation of about 4,000 feet. It is, therefore, probably as hardy as O. Haasti, which is found at the same altitude, and hardier than O. stellulata, which is a tender shrub, but as the number of plants of this species grown in the open in this country is decidedly limited, this is, at the present, rather a matter of conjecture.

OLEARIA NITIDA.

One of the finest of this useful group of New Zealand shrubs.

The specimen portrayed in the accompanying illustration is seven feet in height, with a rather greater branch-spread, and it has been exposed to ten degrees of frost, but, although entirely unprotected, not a leaf or shoot has been injured. It is the largest example known to me in the south-west. As will be seen, it is a very attractive object when in full bloom. The small, white, hawthorn-like blossoms are about half an inch in diameter, and are borne so profusely on loose, branching racemes that, as shown in the illustration, they entirely hide the foliage. The leaves are leathery in texture, three inches in length and two inches in breadth, deep green on the upper surface and silvery-white on the underside. The flowers were borne in such abundance that when the withered bloom-clusters were cut off they filled three bushel baskets, showing the enormous number of blossoms that the shrub carried. It blooms in a small state, the plant illustrated when only a foot high carrying three flower racemes.

WYNDHAM FITZHERBERT.

Kingswear.

Hypericum calycinum. — This the St. John's Wort or Rose of Sharon, is one of the commonest yet at the same time one of the very finest of all the hypericums. It is of dense growth, and forms a mass of handsome leafage, while the comparatively large golden-yellow blossoms are borne in great profusion. Another point in its favour is that it will grow on dry banks under the shade of trees.—W. T.

A NOBLE TULIP TREE.

Of the several charming approaches to the ancient and highly picturesque market town of Horsham, pride of place may well be given to that portion of North Street leading from the railway station for about one-sixth part of a mile, in close proximity to the eastern side of Horsham Park, and ending in the spacious Carfax. This portion of the highway, excepting at its two ends, is immune from the proximity of dwelling houses, with the exception of the mansion of Horsham Park, the ancient seat of the Hurst family, the present owner being R. H. Hurst, Esq., whose property comprises some hundreds of acres in the parish of Horsham.

Leaving the railway station, and proceeding towards the town by way of North Street, the visitor is immediately, on the right, confronted by a group of ancient detached cottages, with spacious front gardens, backed by tall old English elms, principally the abode of rooks; and these cottages might well belong to some old-world village. Additional evidence of the antiquity of Horsham is furnished by the irregular lines and picturesque chimneys of an old and commodious house on the left, which is now arranged in three tenements, but still affords an interesting example of sixteenth-century architecture. The road skirts the ivy-capped wall of Horsham Park, and between the road and the six-feet flagged footway there is a broad stretch of turf, which in its widest part has a breadth of twenty yards.

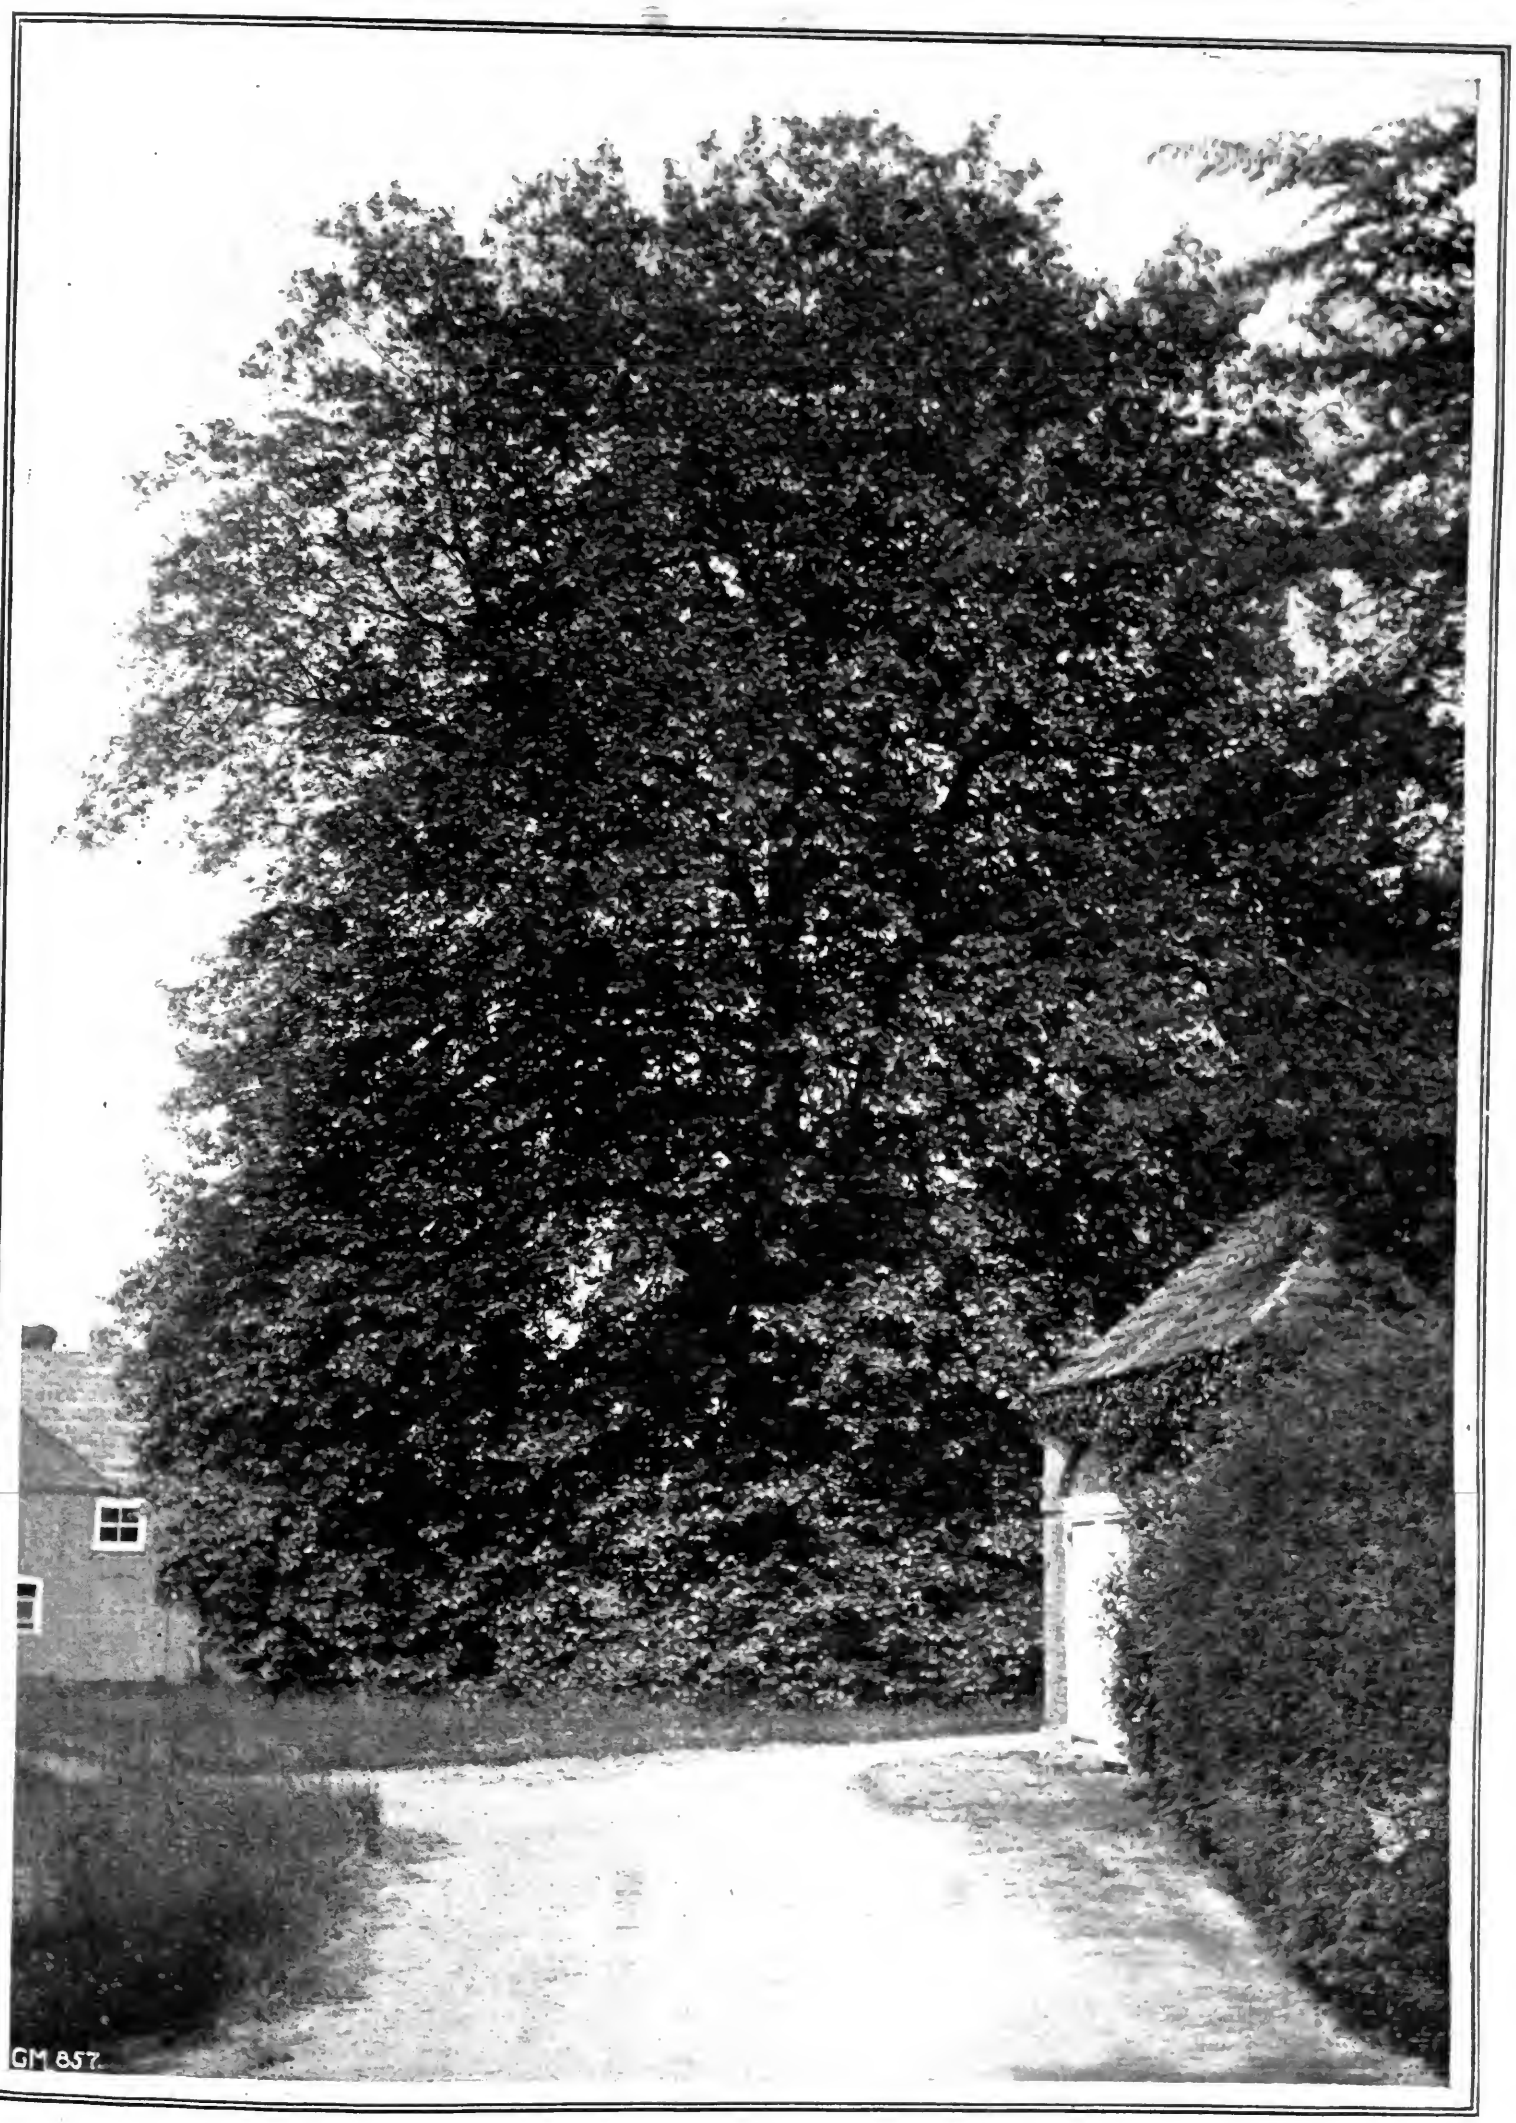
The mansion of Horsham Park is passed on the way, and the magnificent tulip tree (Liriodendron tulipifera), which forms one of the most noteworthy of the arboreal features of the park, is seen in close proximity to the long carriage drive, and immediately opposite to the east facade of the sixteenth-century stone-built mansion. Here its enormous proportions at once arrest the attention of even the most unobservant of the passers-by, and especially is it attractive when its myriads of flowers crowd its branches. There appears to be no record of this magnificent veteran, but it is assumed that it was planted when the mansion was built. If planted thus early, it is one of the oldest specimens in England. It is a matter of interest that in the famous gardens of Leonardslee, the residence of Sir Edmund Loder, there is a specimen which also ranks high among the more remarkable examples of the tulip tree in this country.

The Horsham Park specimen has attained a height exceeding 100ft., and the trunk at 4ft. from the ground has a circumference of 16ft. Not only has the trunk reached a great height and attained to a large diameter, but the branches are remarkable for their splendid development. It will be seen from the illustration which accompanies these notes that the wide-spreading branches extend from the top to within a short distance of the ground, the great masses of rich, glossy green foliage producing a glorious effect. The deeply corrugated bark is not the least attractive feature of this stately native of North America. Another feature of interest has been the annual seeding of the specimen for many years past, and the persistency with which the seed-vessels are retained during the winter months. Taking into consideration the noble proportions to which, under favourable conditions, as in this case, the tree attains, the amplitude of the curiously-cut leaves and the charm of the quietly-coloured flowers, it may be averred that no other deciduous timber tree that has found its home in England can compare with the tulip tree.

By the courtesy of the present life-occupier of Horsham, I have been able to send you the photograph of the tree taken by Mr. W. E. Mitchell, Horsham.

It may be added that growing in the courtyard of the mansion is an equally fine specimen of the London plane, one of the most noble of the many forms of arborescent vegetation. It is of great height, and the drooping, stalwart branches spread over the lawn, and occupy an area fully 300ft. in circumference. Thus, as will be readily conceded, this richly-timbered demesne has among its features two distinct exotic deciduous trees, hardly to be exceeded for age and size in England.

Horsham. William Gardiner.



A REMARKABLY FINE SPECIMEN OF THE TULIP TREE

In the grounds of Horsham Park, the residence of R. H. Hurst, Esq.

IXIAS.

There is a wide range of very beautiful, distinct colours and shades of various colours among the ixias. Many very dry borders are not occupied by flowering plants simply because they may be raised and considered too dry. If ixias are planted very little sand will be needed for the strong-growing varieties, but the smaller ones will be much benefited by having some sand added. After growth is active the soil should be watered in much the same as when ixias are grown in pots. There will not be any difficulty in cultivating them in such borders if the general watering be attended to and the growing plants lightly protected from severe frosts; indeed, a little protection from all frosts, light though they may be, will prove beneficial. As the stems of the flowers are long and wiry, they are splendid for cutting and placing in vases, and, of course, the bulbs may be grown in pots, flowered, and used in this form in the dwelling-house. The following are a few of the best varieties to plant for general effect: Prestios, white, with dark red eye; Azurea, azure-blue, maroon eye; Excelsior, bronzy-scarlet, black eye; Sarnia's Glory, yellow, black eye; Vulcan, crimson, shaded orange; White Swan, white, with blue eye; Lady Slade, pink, white eye; Duchess of Edinburgh, white and rose; and Sunbeam, orange, striped crimson.

M. L.

SUMMER FLOWERS IN BATTERSEA PARK.

Much interest is centred around the old English garden, the opening of which was recently referred to in THE GARDENERS' MAGAZINE. It forms a quiet retreat from the bustle that prevails, especially during the holiday period, in the other parts of the park, for Battersea is a populous neighbourhood, and the park is much favoured by the rising generation. In the old English garden, however, children are not admitted unless in charge of a responsible person, while dogs are also excluded. Owing to this, it is much appreciated by the more staid portions of the community as a spot where they can enjoy their book, and, in some cases, pipe, in peace. Their pleasure is further enhanced by the fact that comfortable seats are plentiful.

The garden itself is cut up into beds by paths radiating from a central pond or basin of water. These beds are planted with a great variety of subjects, mainly of the better class of hardy herbaceous plants, such as pentstemons, antirrhinums, hollyhocks, the dwarfer sunflowers, Chrysanthemum maximum, salvias—particularly striking being Salvia nemorosa virgata—and many others. Dahlias and sweet peas are also there, while some beds of roses have many admirers.

A notable feature is the fact that most of the beds are broadly edged with, for the most part, subjects of a cool restful character, such as Cerastium tomentosum, pinks, and especially Nepeta Mussini, whose greyish-green foliage and lavender-blue flowers impart just that feeling of quietude that one might associate with an old English garden. A pergola, of course, is there, to be in time furnished with the better sorts of climbers, such as roses, clematis, etc. To obtain an immediate effect this season some of the quicker-growing kinds, such as strong-growing tropæolums and Cobæa scandens, have been utilised, but they will in time give way to the others.

The bedding arrangements in various parts of the park are particularly good, though, in some cases, the effects of the drought are visible. In the sub-tropical portion, where watering can be freely carried out, the plants are in splendid condition.

Fuchsias have been well suited by the rather dull summer we have experienced, and are, at Battersea, as well as in the other public parks and gardens, in very fine condition. At Battersea they are freely used as a foreground to borders of shrubs, and, in this way, are seen to very great advantage. They are also employed for beds, but scarcely to the same extent as they have been in some previous years. One striking thing in connection with the summer bedding is the number of uncommon, yet pleasing, combinations that are to be seen, a few of which can for a brief description.

One bed occupying rather a commanding position contains a mixture of tall plants of Veronica Andersoni variegata, and the deep scarlet-coloured Lobelia cardinalis Queen Victoria, with a few plants of Salvia patens, the whole being edged with blue lobelia. On paper this does not seem much, but in itself it is really effective.

Another pretty bed has a groundwork of a viola with mauve flowers, edged with the yellow-leaved Fuchsia Golden Treasure, while dotted over the bed (which is a large one) are good examples of Veronica Andersoni variegata, heliotropiums, Gnaphalium microphyllum, and Fuchsia Henrich Henkel, this last being in exceptionally fine condition.

A bed of salmon-coloured clarkia, overtopped by the large pinnate-leaved Melianthus major, is also very pleasing. An arrangement that, as seen from a short distance, appears somewhat puzzling is a bed carpeted with blue lobelia, thickly dotted with young vigorous plants of Fuchsia gracilis variegata, these latter being about two feet high. Towards the outside are some good cockscombs, and the edging is formed with Gnaphalium lanatum.

Good examples of the uncommon Sutherlandia frutescens form the most prominent feature of another bed, the plants being plentifully furnished with their bright red clianthus-like blossoms. These sutherlandias spring from a groundwork of variegated holcus and Begonia semperflorens Ruby, the whole being bordered with a broad band of Koniga maritima.

A strange mixture, yet, at the same time, a very pleasing one, is a bed furnished with coloured-leaved fuchsias, among which the variety Sunray is very conspicuous. Alternated with the fuchsias are good examples of Celosia pyramidalis, while there is a thick undergrowth of Primula malacoides, Koniga maritima, and blue lobelia.

The strange, yet, at the same time, pretty pink-flowered Statice Suworowi, associated with Begonia Corbeille de Feu, and edged with koniga, is admired by many. Some particularly large examples of the bright red form of Celosia pyramidalis, springing from a dense mass of Chlorophytum elatum variegatum, and bordered with Koniga maritima, form a very noteworthy bed.

Though many other uncommon, yet, at the same time, effective, combinations may be seen, I will limit myself to but one more, namely, a bed of Fuchsia Golden Treasure and Browallia speciosa major, interspersed with well-furnished examples of Abutilon Thomsoni.

It must not be thought that the whole of the beds are furnished with such a varied collection of plants, as a large one consists solely of the double-flowered Ivy-leaved Pelargonium Galilee, both dwarf and standard plants being used. Although this pelargonium was sent out twenty-six years ago, it still remains the most popular of all varieties. Another bed, which is simply a large mass of tall, well-flowered Plumbago capensis, forms also a delightful feature.

Battersea Park possesses a fair collection of succulents, and this year the major portion of them are effectively grouped on a couple of mounds near the lake. Among the different subjects may be noted agaves, aloes, opuntias, echeverias, of which E. metallica is particularly fine, and yuccas in variety. The background is carpeted with Mesembryanthemum cordifolium variegatum, and the forefront with the golden-leaved form of Sagina procumbens. One succulent is very prettily in bloom, namely, Rochea falcata, and the closely-packed heads of bright red flowers, with conspicuous yellow anthers, are very telling.

While the summer bedding forms such an admirable feature, the naming of the different subjects with which the beds are planted might certainly be much improved, for even where there is a label it is often a difficult matter to find it. With regard to the tree and shrub life, it may be planted out that Battersea Park was planted many years ago, so that the majority of the trees have now had time to acquire their matured character. W. T.

THE SNAPDRAGON AND ITS RELATIVES.

No one who is at all observant, and has opportunities for visiting gardens in various parts of the country, can have failed to note that recently the antirrhinum, or snapdragon, has come to the front in a very remarkable fashion. Its peculiar flowers, shaped like a dragon's head, and capable under lateral pressure, of opening and closing its jaws in a very dragon-like way, have been so developed in colour and size as to render it a worthy competitor for preference even in gardens of the highest class, instead of, as in the old days, being mainly an ornament of the cottage garden. It has assumed the most brilliant and varied tints in most charming combinations, and the plant itself has, by selection, been greatly increased, or reduced, in size, so that now we have dwarf, medium, and giant varieties to suit very varied tastes.

The flower of the snapdragon, as indicated above, is very remarkable in form, and presents one of the most striking examples of modification of shape in response to the selective action of the fertilising insects who visit it. Without any such useful object to the flower, man has, however, independently of such subtle influence, materially increased this faculty of development, and, in a comparatively infinitely shorter period modified, as already said, shape, colour, and size to an enormous extent, so as to transform merely pretty flowers into really splendid ones. This being so, a little knowledge, not only of the antirrhinum itself, but of its probably unsuspected relatives, may not be out of place.

The antirrhinum then is one of a very large family, viz., the scrophulariaceæ, or figworts, comprising nearly two hundred genera, made up of about two thousand species. Among these are the familiar flowers, the schizanthus, salpiglossis, calceolaria, verbascum (mullein), pentstemon, mimulus (musk), digitalis (foxglove), veronica, and linaria, in which last Linaria cymballaria, which covers old walls in many places, shows clearly the relationship by its tiny blue snapdragon flowers on a smaller scale. To those who know the flowers of these several genera the great difference between themselves, and, as a rule, that between them and our particular theme, the antirrhinum, will raise the question as to what really constitutes a true plant family. But the botanist will tell us that one and all, despite the difference in the make, etc., of the flower, are linked together by a similarity in the organs of reproduction which persists recognisable to botanical eyes, throughout all the members of the family or order, which, as herbs or shrubs, are generally distributed over the globe, both in temperate and tropical regions. C. T. D.

Azaleas.—To assist these to form their flower buds perfectly stimulants must still be applied. They must also be vigorously syringed twice daily to keep them free from insect life. Liquid manure and soot water, with an occasional sprinkling with an approved fertiliser, will meet their requirements.—E. HARRISS.

FLORAL TABLE DECORATIONS.

The article in your issue of August 30 raises an oft-debated question regarding the present style of dinner table decoration as seen at our horticultural exhibitions. It does not seem fair, or advisable, to condemn entirely the "rustic" stand, as it has done good work in promoting that delicate lightness which is so essential to success in the art of table decoration.

The point your correspondent emphasises, on the difference in table decorations one sees at an exhibition, and that which a gardener would arrange for his employer, is fully admitted; and I think the only real solution is to divide the classes, eliminating the rustic stand and restricting the height to eighteen inches in the one, and in the other leaving the choice of stand to the exhibitor. The greatest percentage of what may be described as "simple" tables is usually seen at the National Rose Society's exhibition at the Royal Botanic Society's Gardens, where table decorations are a great feature.

This year saw about forty exhibitors in these classes, but even here the rustic stand was very popular, and secured several premier awards.

It would appear that the choice of stand should depend entirely upon the class of flower to be used, the rustic epergne being particularly suitable for small light blooms and dainty trailing foliage, whilst for roses the bowl is "par excellence."

It is most desirable that a young gardener should be able to see at an exhibition every variety and style of floral decoration; he could then select the best features of each, and adapt the same according to his individual taste; therefore, if for this reason only, every style should be permissible, even if classes are allotted for one particular type of stand only.

I do not agree with your correspondent's statement that he has not seen at the principal shows a half-dozen table decorations he would dare place on a gentleman's dinner table; this is a very sweeping assertion, but, of course, these things are seen according to one's individual taste and opinion.

As the holder of over 400 prizes won in the decorative section at various shows, and having the honour of judging at Shrewsbury, Wolverhampton, Taunton, and other places, the subject is of the greatest interest to me, and I welcome your correspondent's invitation to a discussion of the question.

(MRS.) L. COLSTON HALE.

Virginia Lodge, Warminster.

I sympathise with Mr. Wise in his endeavour to improve the floral table decorations at flower shows, and agree with him in his objection to the tall rustic stands, having had considerable experience of these and other forms in arranging flowers for table decoration for competitive purposes. The executive of the Bishop's Waltham Horticultural Society, of which I am secretary, offer £10 in three prizes for a decorated table, in addition to other classes in which the prizes are of a less value. Therefore, I have an excellent opportunity for seeing the various forms of flower arrangement. We have these rustic stands in quantity, but seldom does an exhibitor who uses one win a leading position, not because the form is objected to entirely, but because there are superior exhibits arranged in bowls and vases or some other receptacle in which the flowers form a low arrangement. As a rule, when sitting at a table decorated with flowers arranged in these rustic stands, you have a mass of silvered wire and often dingy tubes to look at because the latter especially are difficult to cover with flowers or greenery for fear of making the whole too heavy; moreover, the tubes, too, are not large enough to produce an effective floral display.

Many exhibitors nowadays seem to regard this method of arranging their flowers for exhibition as the best that could be devised, but it is doubtful whether any of them use the same stands at home. It is most difficult to convince users of these stands that they are not really desirable to produce a good effect. I will say, in justice to some of these rustic receptacles, that, when they are not more than nine inches high, they can be used most effectively. I am seriously thinking of asking my committee to limit the height of the floral decorations on the tables at our show in the future. In this way we can check the employment of the present-day stand, which all too often reaches quite a yard high, or nearly so, in the centre of the table.

If the conditions are clearly stated in the schedule, exhibitors will quickly conform to the rule rather than miss the £5 cash prize. If other societies will do likewise, there will quickly be an alteration in the style of table decoration at shows. If fifteen inches was the limit allowed for the decorations, the receptacles would be chosen accordingly. My daughter, who has been fairly successful, employs low silver bowls and trumpet-shaped vases, and it is difficult to see what can be more suitable than these; they are even more effective than glass or china. Another difficulty I find exhibitors and judges labour under when express conditions are not laid down—whether the table is intended for daylight or artificial light. In other words a luncheon or dinner table. As is well known, some flowers are excellent in daylight, but quite useless at night. This is a condition that will appear in our next season's schedule, and thus relieve the judges of that irksome duty of determining what the intentions of the committee were when the decorative classes were entered in the schedule.

Swanmore Park. E. MOLYNEUX.

The remarks made by Mr. E. B. Wise, of Swinfen Hall, on the above subject, are of much interest. In many instances ladies are specially told off to judge the floral decorations at flower shows, they being considered to possess a more refined taste and superior judgment than the usual judges. But in how many large establishments, may one ask, does the lady of the house arrange the flowers? As your correspondent points out, it is generally the foreman or decorator who has charge of the decorations, and, as these in course of time become head gardeners, one fails to see where the superiority of taste and knowledge of the lady judge comes in. Many of them, in all probability, never saw a dinner table in a large establishment after it had been decorated by a competent person. It has not fallen to my lot to see any of those rustic adornments one is accustomed to see at a flower show placed on a private dinner table, as they would, in most cases, be out of place.

In compiling schedules for shows, it would save both judges and exhibitors much trouble and annoyance if those responsible for their preparation would take more pains to define what is meant by certain terms used. As, for instance, "Dinner table decorations on a table 4ft. by 3ft." How is it possible to make a proper display on a table of this size? To place as many flowers on a table of such dimensions as would be required for one to seat eighteen or twenty persons would be absurd. A full-sized dining table is nearly double the width with length in proportion to the number of guests. It would be far nearer the point, when a table of this size is given, to express the decorations as for the centre of a dinner table. One usually sees at flower shows a large rustic ornament placed in the centre from two to three feet high, with four small ones placed at the corners; such would be lost on a table twenty feet long, while the centrepiece would be too tall, and would hide from view those sitting on the opposite side. There would be far more satisfaction in competing were tables provided of suitable sizes to seat ten or a dozen persons. Visitors would then have some idea what a dinner table is like when properly decorated, and those competing would have a far better chance of displaying their taste and skill. As a rule, the floral decorations are not brought nearer the table's edge than fifteen inches, therefore tables four feet wide would be ample to show them, though a full width table would be better.

No decorations should be so high as to prevent the guests seeing each other, unless it be an odd bit or two of light grasses. Guests usually like to be able to see their vis-a-vis, and anything that obstructs the view is objectionable. True, we sometimes see massive silver ornaments employed, but when these are used the seats are usually so arranged that they do not come directly opposite the persons seated at the table. Where vases over fifteen inches high are used, these ought to be of a slender character, and only flowers of a light, graceful nature used in them, those of a heavier type being kept for those that are shorter. Too many colours should be avoided, an arrangement where not more than two are employed usually produces the best effect. There is not now the same difficulty in using certain colours as there was before the introduction of electric light, many being now employed that were formally useless. Flowers always show to advantage in clear glass vases, therefore such should be used when possible.

H. C. P.

GERMAN AND FRENCH POTATO CROPS.

His Majesty's Consul at Stettin (August 19) states that, owing to the cold and wet weather experienced during the last few weeks, the prospects of the potato crop in Pomerania have become less favourable. The yield is, however, officially estimated at from average to good, and should the weather improve a good crop is generally expected.

Present wholesale prices per cwt. in Stettin are as follows: Early red potatoes, 2s. to 2s. 6d.; early white, 2s. 6d. to 3s.; oval blue, 3s. to 3s. 6d.; and kidney, 2s. 6d. to 3s. Exports from this port in 1912 amounted to 139,934 cwt., of which 3,857 cwt. were exported to the United Kingdom. The corresponding figures in 1911 were 390,639 and 104,218 cwt., and in 1910 625,542 and 2,274 cwt.

His Majesty's Consul at Danzig, under date August 20, states that definite estimates of the yield of potatoes in West Prussia this year are not yet available, but if fine weather continues and disease does not set in good crops are expected. Current wholesale prices range from about 2s. to 2s. 6d. per cwt.

The Board of Agriculture has received a report, dated August 23, from His Majesty's Consul-General at Berlin, stating that the almost incessant rain which has fallen during the month has caused deterioration of the potato crop, and it is questionable whether a fine spell of weather coming now would be sufficient to repair the damage. Complaints of disease are general, but principally among the early potatoes, the yield of which will be unsatisfactory. Late potatoes are also suffering to some extent from disease, but should weather conditions improve in the immediate future an average crop may be expected. It is probable that, even under the most favourable conditions that may now ensue, the crop in the whole of Germany will fall below that of 1912—namely, 49 million tons—and it may even not exceed that of 1911—namely, 34 million tons. Germany will probably have to import potatoes to a greater extent than formerly, and prices will probably rise.

His Majesty's Consul-General at Paris (August 25) states that forecasts point to an average crop of potatoes being obtained in France. Most varieties are not dug before September. The principal varieties on the market at present are the Early Rose and L'Institut de Beauvais, prices for which range from about £3 13s. to £3 17s. and £3 6s. to £3 14s. respectively per ton f.o.b., to French Channel ports, and in bags of about 200 lbs.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

MILTONIAS.—Some of the early-flowering varieties are now commencing to make new growths, and plants that may require repotting, should receive the necessary shift. With reference to M. vexillaria, I wrote at some length in the spring of the year, pointing out the different methods adopted by various growers, and advocated repotting just before the plants showed their flower spikes, in localities where the fogs cause so much loss of foliage during the late autumn and winter months. When the plants are grown where the atmosphere is free from impurities, it is advisable to attend to the repotting that is required at the present time. It is not necessary to annually repot large specimens if the potting compost is in a good state of preservation, but should they become hollow in the middle, through loss of leaves, they should be repotted at the present time. Turn them out of their pots, and cut away unnecessary leafless pseudo-bulbs. The old bulbs thus severed may be placed in small pots, and as they usually produce new growths readily, the stock of any desirable kind can be thus increased. Miltonia vexillaria is usually considered surface rooting, and therefore does not require a great depth of compost. The pots or pans should be filled to about half their depth with clean drainage materials. The compost should be graded according to the size of the specimen, using the finer compost for the smaller plants. Good fibrous peat and chopped sphagnum moss, with sufficient sand, broken crocks, and charcoal to render it porous, form an excellent compost. This should be pressed moderately firm about the roots, and finish potting by mounding slightly in the centre. Water as soon as potting is completed, wetting the compost through, soft water being preferable. The plants should be carefully shaded after repotting, and a humid condition maintained about them by syringing between the pots, and spraying overhead whenever the outside conditions permit. Thrips are a great hindrance to the successful cultivation of M. vexillaria. It is well to have the plants carefully dipped in some safe insecticide before repotting. They must be kept under close observation at all seasons of the year, spraying and vapourising at regular intervals being the best means of keeping these pests in check.

MILTONIA ROEZLI and its variety alba, also M. phalænopsis, are best grown under stove conditions, a humid position, where there is an abundance of condensation at all seasons of the year, suiting them admirably. Especially is this the case where the position is within close proximity to the glass. In such a position the pots may be plunged to their rims in growing sphagnum moss. The repotting necessary should be attended to at the present season. Provide ample drainage and a compost as advised above. — H. J. CHAPMAN, Oakwood Gardens.

STOVE PLANTS.

STOVE CLIMBERS.—Whether planted out or grown as trained specimens in pots, these should for some time hence be kept rather drier at the roots, and, if necessary, be subjected to a final thinning of the growths to ensure thorough ripening of those remaining, and also to give as much light as possible to plants growing beneath them, this applying especially to such climbers as Clerodendron Thomsonæ, dipladenias, and Hexacentris mysorensis.

GLORIOSA SUPERBA.—When this beautiful flowering plant has passed its best, water should be gradually withheld. Allow the growths to remain until the tubers are well ripened, when the pots may be placed in a dry position until the tubers are required to be restarted in spring.

STEPHANOTIS FLORIBUNDA. — This lovely fragrant climber requires rather less water from now until the end of the winter, but, being quite evergreen, it must not be allowed to remain in so dry a condition as to cause the slightest shrivelling of the wood.

ALLAMANDAS will continue to bloom for a time, and, unless required for flowering early, should not be unduly hastened to a condition of comparative rest.

BEGONIA GLOIRE DE LORRAINE.—Discontinue the removal of the flower buds of those required to bloom from mid-October onward, and to maintain a succession allow batches to commence flowering at intervals of about three weeks. As the flowers open remove the plants if possible to a rather drier atmosphere that the flowering season may be prolonged.

GENERAL REMARKS.—Shading will be necessary only during the very warmest part of the day, and may shortly be entirely dispensed with. All permanent shading should be washed from roof and house sides. Syringings must be less frequent, generally speaking, once daily in bright weather in the middle of the morning being sufficient; morning and afternoon damping between the plants will yet be necessary. To have the heating arrangements in good condition it is advisable to flush out the boilers. Flues and chimneys should be cleaned and necessary repairs attended to as early as possible. In the stove the temperature should not exceed 70 degrees at night, or the night temperature of the intermediate house 65.—H. PRIME, Hatfield Gardens.

FRUITS UNDER GLASS.

EARLY VINES.—Root-lifting, top-dressing, and any other details should receive attention at the first opportunity. This should be practised when the vines have become weak owing to the compost being exhausted, and needs being replaced with soil of better quality. Sufficient compost must be prepared in quantity equal to the probable demand, using a fair addition of lime rubble, charcoal, bone-meal, and also a moderate sprinkling of some approved vine manure. Commence at the extreme front of the border, and gradually work out the old compost with forks, taking care of all the roots as the work proceeds. The best course is to tie them up in moist bundles until the drainage is rendered efficient, and the border made ready for the new compost. New turf grass, side downwards, forms an excellent base for the compost, which is wheeled in and made thoroughly firm by treading until high enough for the first layer of roots emanating from the lowest part of the undisturbed border. Spread the roots out evenly, removing all faulty or injured parts with a sharp knife, place a little soil over them, and make firm, following this with another layer until all is finished. Keep the vines close during the progress of the work, and in a moist condition; and in severe cases shade, especially if the roots are wholly inside or outside, as the case may be.

TOP-DRESSING VINE BORDERS.—This being an annual operation, the best time to perform the work is as soon as the leaves fall, and pruning can take place, or even before on outside borders. Prick over the borders carefully, remove all old mulchings, and remove the soil carefully, when the surface rootlets will be laid bare. After this has been done apply a dressing of fresh compost similar to the above to the depth of about two inches, making all firm as the work proceeds.

LATE GRAPES. — These must now be pushed forward to have them thoroughly ripe by the end of the month, or they will not keep well during the winter. Pinch all laterals, and allow all light possible to play amongst the fruit.

POT VINES intended for starting in November should now be ripe and resting with their pots covered with some non-conducting material to prevent injury from drought. They will not require much water after the foliage is ripe, but the ball of soil must not be allowed to shrink from the sides of the pots, as soon happens if neglected. As the canes cannot be too well ripened, this point should have proper attention before the leaves fall, after which all excitement must cease, and the vines given perfect rest. A wall facing west is a good place for them, provided the roots are well covered. Young vines, which are grown as cut-backs, will soon be ripe and fit for removal to a high, airy house, or they will do equally well against a sheltered wall. Like the preceding, they must not be allowed to suffer from dryness at the roots. The young canes should be securely fastened to the wall to prevent injury by winds, and also to give the buds the fullest benefit of sunheat. Where it is intended to make fresh borders for the coming winter, the sooner the materials for their composition are prepared the better. — F. JORDAN, Warter Priory, York.

THE FLOWER GARDEN.

ROSE CUTTINGS.—There are many advocates for growing roses on their own roots, and whenever the constitution of a variety is such as to enable it to flourish without having to derive support from a vigorous stock, it has much to commend it. The nuisance of suckers springing up from the stock is overcome, and also the development of the root and stem is more in agreement, thus reducing to a minimum the liability of plants growing as dwarfs being broken off by rough winds immediately under the surface of the soil. The present time is a suitable one for inserting cuttings, which should be selected from young, matured growths, and taken off with a sharp knife at the heel. Shorten back the tip of the growth, so as to leave the cutting about 12in. in length. In favourable districts most varieties will root if inserted in rows in the open ground, but in others they require the protection of hand-lights or cloches, and in such cases the cuttings must be inserted in groups, over which the covers will fit when it becomes necessary late in the autumn to use them.

LAVENDER, ROSEMARY, AND SANTOLINAS.—It is a sound practice of always having a stock of young plants of these old garden shrubs in hand, as they are very susceptible to dying off in an unaccountable manner, especially on cold, wet soils. Cuttings inserted at this season under hand lights in an open border will strike readily.

BULBS.—At this period, just previous to the time when the general run of autumn planting comes on, every opportunity should be taken advantage of to forward as far as possible all work that will relieve the pressure later on. The good results following on the early planting of bulbs is generally recognised, and where any naturalising is contemplated, there is no time better than the present for carrying it out. In many gardens the cultivation of Darwin and May-flowering tulips and special varieties of narcissi form an important feature, and quarters are allotted to them. In such cases planting the bulbs can be proceeded with after the ground has been well dug and enriched.

HARDY CLIMBERS.—These have nearly completed their season's growth, and all young shoots should be made secure against rough winds, either by tying in or nailing. While this work proceeds, thin out any superfluous and undeveloped growths. By judicious thinning those remaining are given the conditions most favourable for becoming well ripened. It need hardly be said that the maturity of the growths will greatly increase flower production.—T. B. FIELD, Wych Cross Place Gardens.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

There was a fair-sized exhibition at Vincent Square, Westminster, on Tuesday, September 9, but the attendance was small, and everyone seemed to be more interested in discussing holiday matters than in the plants and flowers on view. Enthusiasm arose, however, over one display, i.e., that of grapes and orchard-house fruits from Warter Priory; it is doubtful whether a finer lot of dessert fruit has ever been set up at one time from one private garden. Border flowers, dahlias, and orchids were shown freely, but novelties were few.

HARDY FLOWERS.

Phloxes provided the bulk of the large exhibit of hardy flowers shown by Mr. Jas. Box, Lindfield. Very effective were the violet-purple Gloire de Marc; Duguesclin, lavender; Toreador, pink, with very dark buds; the fine white Frau von Lassberg, and the deep pink Meteore. With the phloxes were associated groupings of Gladiolus America, the graceful Watsonia rosea, and W. Ardernei, Lilium sulphureum, and L. nepalense. Mr. A. L. Gwillim, Cambria Nursery, Sidcup, does not confine his attention to tuberous begonias, for on this occasion he set up a bank of hardy flowers wherein Campanula Burghalti, with its long-lobed bells, Aster Sidcup White, Helianthus sparsifolius, one of the best of perennial sunflowers, and Senecio tanguticus were notable kinds.

Messrs. Wells and Co., Merstham, grouped phloxes effectively in large stands, and set up about thirty varieties of these popular and fragrant flowers; King Edward, crimson lake; Iris, violet; Gloire de Marc, violet-purple; Selma, pink; Elizabeth Campbell, pale soft pink; and the brilliant carmine Gen. von Hentz, were all capital varieties well displayed.

Messrs. Rich and Co., Bath, contributed small bunches of a large number of varieties of phloxes, and the Guildford Hardy Plant Company sent hardy flowers. Messrs. Whitelegg and Page, Chislehurst, contributed pentstemons, liliums, delphiniums, phloxes, and big baskets of blooms of Colchicum autumnale. Mr. G. W. Miller, Wisbech, set up a very bright exhibit of hardy flowers, his Kniphofia Nelsoni major being particularly fine and showy.

Messrs. T. S. Ware, Feltham, were represented by a large exhibit of phloxes, pentstemons, Michaelmas daisies, and delphiniums. Phlox Countess de Jarnac, with creamy-white variegated leaves and small pink-centred flowers. Aster Feltham Blue shown by this firm gained an A.M., and is soft blue, with flowers of fair size carried lightly on wiry, blackish stems. Salvia uliginosa, a fragrant-leaved, blue-flowered, hardy perennial, gained an A.M., and was shown by Mr. C. Turner, Slough. Enchantress Supreme, a lovely fragrant pale pink perpetual carnation, was shown by Messrs. Allwood Brothers, Haywards Heath; it is of fine form and size, and promises to be a first-rate variety.

The quaint little Mazus pumilio was shown by the Wargrave Plant Farm, Lim., The Arcade, Liverpool Street; this firm had a selection of Michaelmas daisies, phloxes, and other autumn flowers.

A very interesting exhibit was the one of grasses set up by Mr. Jas. Macdonald, Harpenden, who had about half a dozen pots each of a large number of species suitable for lawns or pastures, or of purely decorative character, all margined around by the lovely velvety grass grown on prepared material, and used like green velvet. Very pretty were Lagurus ovatus, Poa amabilis, Briza minima, Anthoxanthum gracilis, Hordeum jubatum, Festuca stipoides, Eragrostis abyssinica, E. elegans, and Bromus macrostachys, all of decorative value, and conspicuous among the fifty or sixty species staged.

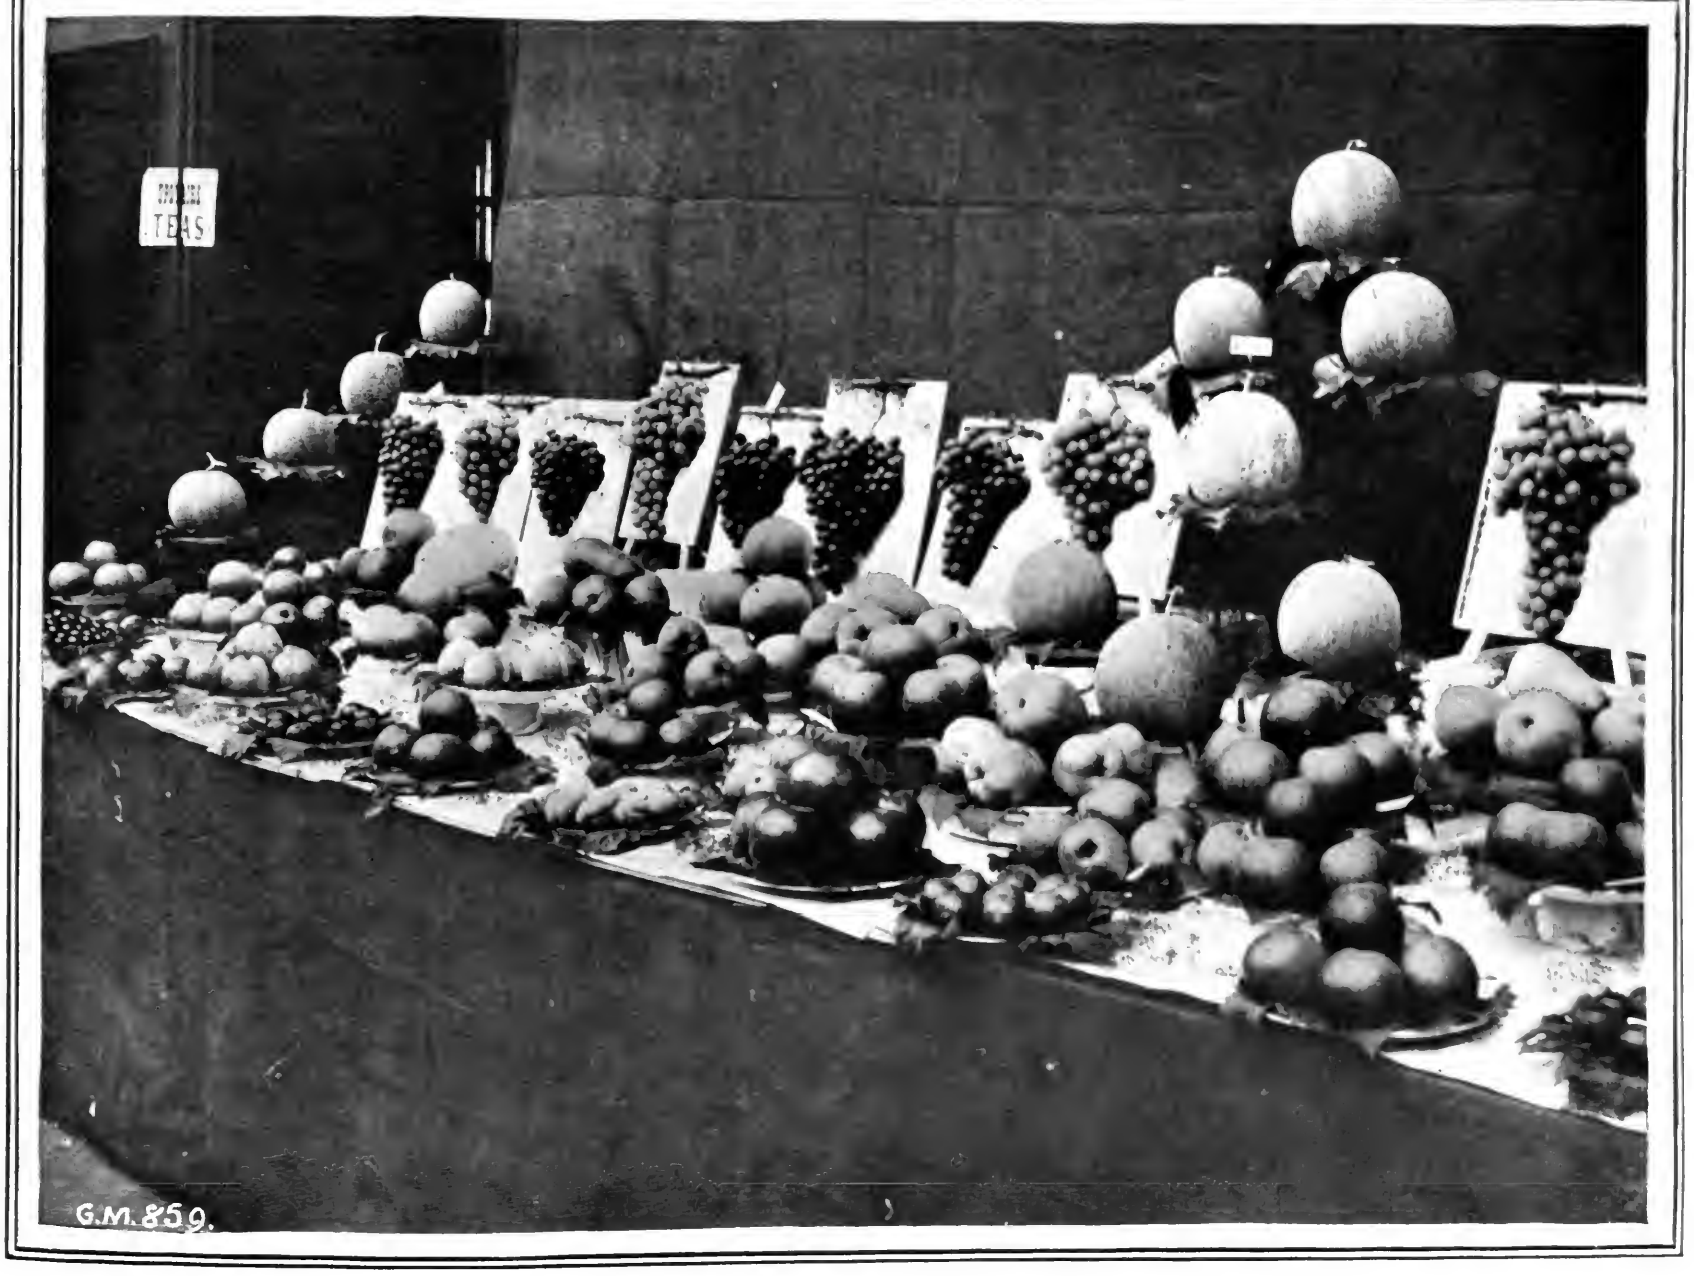
DAHLIAS, CARNATIONS, ETC.

An extensive display of dahlias right across the end of the hall, arranged boldly by Messrs. Carter Page and Co., London Wall, attracted a great deal of attention.

Messrs. Dobbie and Co. confined their attention to collarette dahlias, and made up a brilliant exhibit, their Queen Anne, Diadem, Queen Bess, and Princess Louise being quite dazzling, while Inchmarnock (A.M.), soft salmon scarlet, with yellow collar, was not less effective. Conspicuous in the exhibit of dahlias from Messrs. J. Cheal and Sons, Crawley, was the variety named Crawley Star; in outline this suggests a cosmea with two rows of deep pink petals, with a crimson zone around the yellow disk; a very pretty and free variety.

A deep cerise-pink perpetual carnation, named Pioneer, a variety of good size and substance, was well shown by Mr. C. Englemann, Saffron Walden, and is a novelty for 1914. Messrs. Stuart Low and Co., Enfield, exhibited the beautiful carnation Baroness de Brienen, and the useful Chironia ixifera. The rare and extraordinary Brunsvigea Josephinæ was shown by Mr. Sherlock, gardener to G. W. Tyser, Esq., J.P., Oakfield, Mortimer; this has reddish flowers in a big umbel, and on long footstalks.

A selection of autumn-flowering veronicas, in pots, a collection of maidenhair ferns, with nephrolepis and the tall Selaginella cæsia arborea, made up a large exhibit from Messrs. H. B. May and Son, Edmonton. Messrs. Wm. Cutbush and Son, Highgate, brought up good batches of the bright fuchsias Coralle, Gottengen, and Thalia. A



PART OF THE GOLD MEDAL EXHIBIT OF DESSERT FRUITS.
Exhibited before the Royal Horticultural Society at Westminster, on Tuesday, September 9, by Mr. F. Jordan, gardener to Lady Nunburnholme, Warter Priory, Pocklington, Yorks.

THE NATIONAL CHRYSANTHEMUM SOCIETY'S
EXHIBITION OF EARLY-FLOWERING

CHRYSANTHEMUMS

Will be held at the

CRYSTAL PALACE,

On OCTOBER 1st and 2nd, 1913.

Write for Schedule (post free) to the Secretary,
Mr. RICHARD A. WITTY,
72, Savernake Road, Gospel Oak, S.W.

ADMISSION TO PALACE (including Show), 1s.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

beautiful salmon-coloured nerine named Rotherside was exhibited by Messrs. Herbert Chapman, Lim., Rotherside, Rye; it has a fine truss, good flowers, and pleasing colour.

ORCHIDS.

The boldest exhibit of orchids on this occasion was to the credit of Messrs. Armstrong and Brown, Tunbridge Wells. This firm chiefly set up well-grown lælio-cattleyas, such as L.-c. Bletchleyensis, L.-c. George Woodhams (A.M.), very handsome in mauve and purple; L.-c. Aphro-Nysa, L.-c. Armstrongæ Orchidhurst var., the pretty little L.-c. Rainbow, with Cattleya Iris in fine form, and the exquisite Brasso-cattleya Maronæ, and a few odontiodas, including O. Seymouræ (A.M.). Messrs. Sander and Sons, St. Albans, showed L.-c. Phœnix, and such interesting orchids as Catasetum macrocarpum, and unnamed species of Warrea and Angræcum. Cypripedium Swani, with a bold, rounded, claret-veined, dorsal sepal, was conspicuous in the little group of orchids from Messrs. Swan and Price, St. Albans.

The yellow and soft mauve Lælio-cattleya Anchela was shown by Pantia Ralli, Esq., Ashtead Park, Leatherhead. Mr. W. H. White, grower to Sir Trevor Lawrence, Bart., Dorking, staged fine specimens of Zygopetalum maxillare and Z. m. Sanderianum, and a smaller plant of Angræcum cundatum. Lælio-cattleya Mrs. D. Macmaster (L.-c. Luminosa crossed with C. aurea), shown by Mr. Hopkins, gardener to Francis Wellesley, Esq., Westfield, Woking, was very bright in old gold, yellow and pale crimson. L.-c. Lustre, Holford's var., from Sir George Holford's collection at Westonbirt, was remarkable for the deep purple stripe on the light mauve petals. Brasso-cattleya Pittiana, Cattleya Warscewiczi Countess of Derby, with white sepals and petals, and C. Thayeriana alba were all shown by Mr. Thurgood, gardener to H. T. Pitt, Esq., Stamford Hill.

Messrs. Charlesworth and Co., Haywards Heath, had a small but pretty exhibit of Dendrobium Phalænopsis Schroderianum, miltonias, the elegant Oncidium incurvum, Calanthe violacea, Sophro-lælia Heatonensis, Lælia monophylla, and the very quaint Bulbophyllum grandiflorum. Messrs. Hassall and Co., Southgate, had Cattleya Iris in good form, and Brasso-cattleya Queen Alexandra, white, and beautifully fringed, Cœlogyne pandurata, and Cattleya iridescens. Messrs. J. and A. McBean, Cooksbridge, showed some finely-coloured odontiodas, good forms of Odontoglossum crispum, and other good things. M. Maurice Mertens, Ghent, brought over a little set of handsome unnamed hybrid orchids.

A good specimen of Cirrhopetalum Medusæ, with sixteen heads of its slender, hair-petalled flowers, was shown by Mr. J. Lees, gardener to C. de Quincey, Esq., Oakwood, Chislehurst. A large basket of flowering plants of Spathoglottis zebrina, a variable hybrid between S. Fortunei and S. plicata, was brought by Mr. Collier, gardener to Sir J. Colman, Bart., Gatton Park, Reigate.

FRUITS.

A superb collection of fruit, set up by Mr. Jordan, gardener to Lady Nunburnholme, Warter Priory, was the finest exhibit in the show. It consisted of grandly-grown fruit, with never a flaw or weak point in any dish. There were about a dozen and a-half melons, and sixteen bunches of grapes, the latter consisting of Muscat of Alexandria, Madresfield Court, Gros Maroc, Black Hamburgh, Barbarosa, and Alicante. The apples, orchard house fruit, were magnificent, the leading varieties being Peasgood's Nonsuch, Gascoigne's Scarlet, The Queen, Washington, Cox's Orange Pippin, Rival, Allington Pippin, Chas. Ross, and Wealthy. The pears were also grand, notably Triomphe de Vienne, Conference, Souv. du Congrès, Marguerite Marillat, Doyenne du Comice, and Emile d'Heyst. Besides these there were Grosse Mignonne, and Nectarine peaches, Pineapple nectarines, and Old Gage, Jefferson, and Golden Drop plums, Brown Turkey figs, and cherries. It was a glorious display, and a triumph of cultivation.

A large and effectively arranged display of choice fruit from Mr. Grubb, gardener to Cecil F. Raphael, Esq., Porter's Park, Shenley, also gained a gold medal. There were good clusters of Madresfield Court, Lady Downes, Muscat of Alexandria, and Canon Hall grapes, excellent melons, peaches, plums, nectarines, and a large collection of apples and pears. The best dishes of the latter were Pitmaston Duchess, Williams' Bon Chretien, Doyenne du Comice, Durondeau, Souv. du Congrès, and Beurre Diel. The apples were not highly coloured, but clean and solid fruits, especially Blenheim Orange, Yorkshire Beauty, Lord Suffield, New Hawthornden, Emperor Alexander, Chas. Ross, Peasgood's Nonsuch, and The Queen. It must be remembered that all the apples and pears shown in this collection were from outdoor trees.

Messrs. Laxton Brothers, Bedford, exhibited some new apples, and the Laxtonberry; The Cropper (Lady Sudeley x Potts' Seedling), and Premier (Mr. Gladstone x Worcester Pearmain), were two of the most interesting of the new apples. Pot-grown figs, and a number of pot grown vines carrying fairly heavy crops of fruit, were shown in some quantity by Messrs. Stuart Low and Co., Enfield.

AWARDS.

No First-class Certificate was granted on this date.

Award of Merit.—To Aster Feltham Blue, from Messrs. T. S. Ware, Feltham; to Dahlia Inchmarnock, from Messrs. Dobbie and Co., Edinburgh; to Salvia uliginosa, from Mr. C. Turner, Slough; to Lælio-cattleya George Woodhams and to Odontioda Seymouræ, from Messrs. Armstrong and Brown, Tunbridge Wells.

MEDALS.

Gold.—To Mr. F. Jordan, gardener to Lady Nunburnholme, Warter Priory, Yorks, for choice fruits; and to Mr. Grubb, gardener to C. F. Raphael, Esq., Porter's Park, Shenley, for fruits.

Silver-gilt Flora.—To Messrs. Armstrong and Brown, Tunbridge Wells, for orchids; to Mr. Jas. Box, Lindfield, for hardy flowers; to Messrs. Carter Page and Co., London Wall, for dahlias.

Silver-gilt Banksian.—To Messrs. Dobbie and Co., Edinburgh, for dahlias; to Messrs. Stuart Low and Co., Enfield, for fruits in pots.

Silver Flora.—To Mr. L. R. Russell, Richmond, for clematis, etc.; to Messrs. W. Wells and Co., Merstham, for phloxes; to Messrs. Charlesworth and Co., Haywards Heath, for orchids.

Silver Banksian.—To Messrs. Hassall and Co., Southgate, for orchids; to Messrs. W. Cutbush and Son, Highgate, for greenhouse plants; to Mr. C. Engelmann, Saffron Walden, for ferns; to Mr. Gwillim, Sidcup, for hardy flowers and begonias; to Mr. Jas. Macdonald, Harpenden, for grasses; to Mr. G. W. Miller, Wisbech, for hardy flowers; to Messrs. H. B. May and Sons, Edmonton, for ferns; to Messrs. T. S. Ware, Lim., Feltham, for hardy flowers.

Bronze Flora.—To Messrs. Whitelegg and Page, Chislehurst, for hardy flowers.

Bronze Banksian.—To The Guildford Hardy Plant Co., Guildford, for hardy plants and flowers; to Wargrave Plant Farm, Lim., The Arcade, Liverpool Street, London, for hardy flowers.

National Dahlia Society.

SEPTEMBER 9 and 10.

The annual exhibition of this society was held at the Crystal Palace, and was arranged in the central transept, where the fine display of flowers produced a very bright effect. The entries were more numerous than last year, in spite of the wet weather experienced during the past fortnight.

NURSERYMEN'S CLASSES.

The premier class for show dahlias, forty-eight blooms, distinct, was only represented by one exhibitor, Mr. S. Mortimer, Rowledge, Farnham, who well maintained the dignity of the show flowers by staging in fine form, W. Powell, Crimson Globe, Standard, Buttercup, H. Walton, Lord Salisbury, Pandora, Jas. Vick, Mrs. Langtry, and Colonist; the flowers were level throughout and beautifully fresh. The competition for twenty-four blooms, distinct, brought out a keen contest, Messrs. Keynes, Williams, and Co., Salisbury, proving the victors with a very fine set in which the following varieties were the most striking: Souvenir, Autocrat, Daniel Cornish (very fine), Emin Pasha (self), Maud Fellowes, Colonist, Gracchus, Chieftain, Florence Franks, and Arthur Rawlings. Mr. Chas. Turner, Slough, followed with some wonderfully bright examples, his best varieties being Arthur Ocock, Gracchus, Colonist, Mrs. D. Saunders, Tom Jones, John Walker, and Seraph; the third prize falling to Mr. M. V. Seale, Sevenoaks. The class for twelve fancy varieties, distinct, found Mr. Chas. Turner leading the way with bright, fresh flowers of W. Pemberton, Mrs. Saunders, Roy Seale, Dandy, Dorothy, and the Rev. J. B. M. Camm. Mr. M. V. Seale was second, having good typical examples of Professor Fawcett, S. Mortimer, Duchess of Albany, Hercules, and Mrs. Saunders; while Mr. S. Mortimer was third.

The premier class for eighteen bunches of cactus varieties, of six blooms each, is always keenly contested. On this occasion the Gold Medal was awarded Messrs. J. Burrell and Co., Howe House Nurseries, Cambridge, who were in fine form, for the flowers were not only large, but of excellent quality as well. The varieties employed were Olympic, J. Woolman, New York, Miss Stredwick, Mrs. Stephens, Red Admiral, Lurid, Indomitable (fine), Tokio, Fred. Wenham, Albatross, Elfrida, Empire, H. H. Thomas, Prima Donna, Mamie, Cygnet, and Flamingo. It must have seemed somewhat strange for Messrs. Jas. Stredwick and Son, St. Leonards-on-Sea, to occupy second place, after holding an unbroken record in this class for about the last dozen years. However, the weather has much to explain to exhibitors; their best flowers were Miss Stredwick, Starlight, Magic, Gigantic (very fine), F. W. Fellowes, and Dorothy Hawes. Messrs. J. Cheal and Sons, Lim., Crawley, were a fine third—in fact, they must have been very close for second place. Here the best bunches were H. L. Brousson, Wild Rose, H. H. Thomas, New York, Rev. T. W. Jamieson, and Lustre.

Mr. M. V. Seale was the only exhibitor for twelve bunches of cactus, and was deservedly awarded first prize; the most striking varieties were Miss Hills, Sultan, H. L. Brousson, Fulgent, Crystal, Snowstorm, Pride of Essex, and Brigadier.

For forty-eight blooms, distinct, on boards, Messrs. Burrell and Co. led off with a grand exhibit, the best examples being Olympic, New York, Herod, Mary Purrier, Prima Donna, Golden Crown, F. W. Fellowes, Geo. Schofield, and the Rev. A. H. Lowe. For twenty-four blooms, distinct,

Messrs. C. Carrington and Sons, The Nurseries, Vicarage Avenue, Derby, won first prize with large examples of New York, Glory of Wilts, F. W. Fellowes, Kingfisher, Mrs. D. Fleming, H. H. Thomas, and Mary Purrier. Mr. H. Woolman, Sandy Hill Nursery, Shirley, Birmingham, was second with flowers of greater refinement. His best examples were America, Mary Purrier, F. Ridout, New York, and Miss Stredwick; Mr. M. V. Seale taking third prize.

The garden cactus class for twelve varieties only secured two entries, but both were excellent, Messrs. J. Cheal and Sons, Lim., winning first prize with good erect bunches of the Hon. Mrs. Greville, Mrs. Landale, Snowdon, Mrs. Freeman Thomas, Mrs. Chas. Foster, Rose Queen, and Sweet Briar. The vases were embellished with berberis, Prunus Pissardi, acers, and grasses most effectively arranged. Mr. M. V. Seale followed with a table sweetly arranged with foliage and berries; the best bunches were Fred Warham, Arthur Pickard, Coral, Light-Lady Bountiful, Brilliant, and Rosemary Bridge. Mr. M. V. Seale was second with good typical bunches of Maud Nicholson, General Kuroki, Owen Thomas, Dream, Mark Twain, and Nymph.

There was a strong entry for six varieties of pæony-flowered dahlias, though all did not stage. Mr. Chas. Turner was well to the fore with tastefully arranged vases of Salome, Aphrodite, Bertha von Suttner, Bayard, Liberty, and Turner. Messrs. J. Cheal and Sons, Lim., were second, having fine vases of Bayard, Fulgens, Melampas, and Liberty; while Mr. J. Emberson, Grove Road Nursery, Walthamstow, was third.

The collarette classes were in fine condition, and stood out conspicuously, for artificial supports are not allowed. Mr. Chas. Turner was first for twelve varieties with good typical bunches of Prince de Venosa, Diamant, Gallia, Albert Maumene, Henri Farman, Abbe Hugonard, and Maurice Rivoire. Mr. J. Emberson was a capital second, staging Lotus, Diadem, Mad. Poirier, Regularity, and Queen Bess in good form. Messrs. J. Cheal and Sons, Lim., were third.

FIRST PRIZE COLLECTION OF TWELVE VARIETIES OF COLLARETTE DAHLIAS,
Exhibited by Mr. C. Turner at the exhibition of the National Dahlia Society.

ship, Sweet Briar, and Mary Purrier. The pompon classes were excellent; Mr. Chas. Turner proved the victor for twenty-four varieties, and it is doubtful if the firm has ever staged these charming flowers in better form. Some of the most conspicuous were Adelaide, Douglas, Silvia, Ideal, Little Beeswings, Ganymede, Nellie Broomhead, Jessica, Cyril, Adela, and Mignon. Messrs. J. Cheal and Sons, Lim., followed with a capital collection, in which were noted Pauline, Madeline, Ganymede, Phyllis, Nerissa, and Norah; while Mr. M. V. Seale was third with a pretty set which were well staged. Messrs. J. Burrell and Co. were the only exhibitors for twelve distinct varieties, and they were awarded first prize. The best examples in this case were Marietta, Bacchus, Ganymede, Nellie Frazer, Girlie, and Eros.

The single dahlia classes do not appear to grow, although they are so much admired by the visitors. For twenty-four varieties, Messrs. J. Cheal and Sons, Lim., led off with some charming examples of Mrs. Joynson Hicks, Bridesmaid, Owen Thomas, Betty, Leander, Glencoe, Princess of Wales, Winona,

AMATEURS' CLASSES.

The amateur challenge cup for twenty-four show varieties was captured by Mr. S. Cooper, Chippenham, who was the only entrant; but he made sure of his position by staging excellent examples of Rev. J. Gooday, Shirley Hibberd, T. W. Girdlestone, Mabel, Prince of Denmark, Henry Clark, Chieftain, Mrs. Saunders, Florence Tranter, Shottesham Hero, and Lottie Eckford. In the class for twelve blooms, distinct, Mr. Cooper again led off with a good level board. His most conspicuous blooms were Chieftain, Frank Pearce, R. T. Rawlings, Tom Jones, and Buffalo Bill; Mr. G. Densley, Nag's Head Hill, Bristol, was placed second; and Mr. H. Tysoe, The Lodge Gardens, Bedford, was third. The silver challenge cup for six vases of garden cactus dahlias was secured by the Rev. A. Bridge, Worth Rectory, Sussex, who staged in excellent style the Hon. Mrs. Greville, Sweet Briar, Snowdon, Mrs. Landale, and Mary Purrier; Mr. M. Howard, Wood View, Moor Road, Chesham, was second; and Mr. W. Passey was placed third.

The silver challenge cup for nine cactus varieties, three blooms each, was won by Mr. F. W. Fellowes, King's Walden, Hitchin, for the second time; his flowers were beautifully bright and fresh, especially Golden Crown, Miss Stredwick, Uranus, Mrs. Stephens, John Riding, Mrs. D. Fleming, and Golden Wave. The Rev. A. Bridge won second prize with Miss Stredwick, Golden Wave, H. H. Thomas, W. Marshall, and Snowdon as his best bunches. Mr. A. H. Farmer, Kitchener Road, Walthamstow, was a capital third. For twenty-four cactus varieties, Mr. H. Peerman, Nantwich, was placed first with a beautiful exhibit, the finest blooms being F. W. Fellowes, Nantwich, Richard Box, Empress, Conquest, H. Peerman, New York, and Golden Wave; Mr. A. H. Farmer was close up for the second prize with fresh, well-coloured flowers; and Mr. G. Densley brought up the rear.

There was a keen contest for twelve cactus blooms, distinct, but Mr. H. Peerman led with splendid specimens of H. H. Thomas, Golden Wave, John Riding, F. W. Fellowes, R. Box, and Mrs. Stephens. Mr. R. C. Unwin, The Green, Histon, Cambs, proved the second prize-winner, having good blooms of Olympic, New York, and Miss Stredwick. Mr. H. Brown, Luton, Beds, was third. This exhibitor, however, secured the premier position for twelve bunches of pompons; some of his best varieties were Censor, Donald, Emily Hopper, Darkest of All, Violet, Bacchus, and Jessica. Mr. A. R. Ironside, The Hamlet, Chippenham, was second with an exhibit that must have run the first prize stand very closely.

The silver challenge bowl for twelve bunches of singles was well won by the Rev. A. Bridge, who staged in capital style Mrs. J. Hicks, Betty, Winona, The Mahdi, Rosemary Bridge, and Brilliant. Mr. A. Brown won second position with a good collection. There was a capital entry for twelve blooms, in four varieties. Here Mr. A. H. Farmer was placed first with a splendid board; the

varieties were Golden Wave, Mary Purrier, New York, and Glory of Wilts. The Rev. A. Bridge was second, and Mr. H. Brown third.

The class for six cactus varieties, three blooms each, found Mr. C. Luckin, Apsley, Thakeham, to the fore, with F. W. Fellowes, Golden Wave, Fred Wenham, and Miss Stredwick; Mr. A. Langridge, Brownlow Road, Dalston, was second; while the third prize fell to Mr. A. T. Tofield, Chandlers Ford, Hants. For the garden cactus class Mr. A. T. Tofield led off with good typical bunches of Mary Purrier and Sweet Briar; Mr. C. Luckin was second.

The remaining amateur classes were mostly well filled by the exhibitors already mentioned. In the open class for twelve bunches of pompon cactus, Messrs. J. Cheal and Sons, Lim., won first prize with good typical bunches of Little Dolly, Wm. Marshall, Firefly, Molly, Goldfinch, The Bride, and Rubin. Mr. M. V. Seale was second, and Messrs. Burrell and Co. third.

There was a splendid entry for six blooms, one variety, but Mr. H. Peerman secured first honours with fine flowers of Fred Wenham; Messrs. Keynes, Williams, and Co. were second with Celestial; and Mr. H. Woolman third with H. H. Thomas.

NON-COMPETITIVE.

The trade displays were quite a feature of the show. Messrs. Hobbies, Lim., occupied a large space with pæony and collarette varieties, arranged in tall stands, while in front the cactus section was well represented with blocks of each variety. Mr. J. T. West staged a fine collection, his cactus and pompon varieties forming his chief feature. The exhibit was relieved with vases of grasses, reeds, and other foliage. Messrs. A. H. Cole, Lim., Swanley, Kent, made a bright and attractive display of collarette, cactus, and decorative varieties in all the best-known kinds. Mr. J. Emberson, Grove Road Nursery, Walthamstow, had a large exhibit embracing all sections; these were well arranged in tall stands and vases, the whole producing a fine effect.

Mr. H. Woolman, Shirley, Birmingham, displayed a good collection, in most sections. His cactus varieties, however, were the chief feature; these were all up to show standard, and produced a pleasing effect.

Messrs. T. S. Ware, Lim., Feltham, had a long run of tabling which they filled with a good collection. The pæony and cactus varieties were nicely arranged with some good foliage. Groups of Germania and The Geisha were very striking, as were also the cactus vadieties, The Imp, Nellie Riding, H. L. Brousson, and Florrie Wells. Mr. J. B. Riding, Nurseries, Chingford, had a large exhibit arranged in stands and vases; the pæony and collarette varieties predominated, while several of the new decorative varieties were used effectively.

AWARDS.

Large Gold Medal.—To Messrs. Hobbies, Lim.

Gold Medals.—To Messrs. T. S. Ware, Mr. J. T. West, and Mr. J. B. Riding.

Silver-gilt Medal.—To Mr. J. Emberson.

Silver Medals.—To Messrs. A. H. Cole, Lim., and Mr. H. Woolman.

First-class Certificates.—To pompon Rosa, from Messrs. Keynes, Williams, and Co.; to Wee Gracie, from Mr. J. T. West; to cactus Dorothy Hawes, also the Gold Medal for the best seedling cactus in the show, to cactus Pierrot, to garden cactus E. F. Hawes, to pæony-flowered John Green, all from Messrs. J. Stredwick and Son.

Duns, Berwickshire.

Although but a small town of little over two thousand inhabitants, there are in the ancient and picturesque borough of Duns quite a host of ardent amateur horticulturists who support their annual flower show in a spirit of zealous enthusiasm that results in an exhibition of garden products, both decorative and utilitarian, deserving of high compliment. The show held on Saturday, September 6, was in all respects a good one, the spacious hall being well filled with exhibits, scarcely, indeed, leaving sufficient room for the accommodation of the interested throng of exhibitors and spectators who gathered together to inspect and discuss the merits of the flowers, fruits, and vegetables staged. Hardy flowers were particularly well shown, and the first prize exhibit of six bunches of herbaceous flowers was of a high standard. Mr. J. A. Taylor may be congratulated upon his skill as a cultivator, and his tasteful arrangement, as well as for his judgment in selecting as subjects Veronica subsessilis, Lobelia cardinalis Firefly, Anemone japonica alba, Helianthus maximus, a very good form of Gaillardia grandiflora, and the bright Monarda didyma Cambridge Scarlet. Mr. Jas. Cockburn showed a creditable set of six show and fancy dahlias, for which first prize was awarded; and other exhibitors competed keenly for the prizes offered for carnations, marigolds, annuals, and sweet peas, the latter, as behoves a town renowned as the home of the Scottish sweet pea champion, being quite a feature. Some useful window plants were exhibited, and a plant of Campanula isophylla alba shown by Mr. Peter Lugton was exceptionally fine. Indeed, it is a long time since we saw a more floriferous specimen of this charming basket plant at any show. Turning from the purely decorative to the utilitarian section, we found a fine array of well-grown tomatoes, potatoes, leeks (some capital examples being staged of this favourite exhibition vegetable), and, in fact, it may be said all seasonable vegetables were plentiful and good.

Fruit, too, was shown, some of the apples being of good size, clear, and bright in colour, and in the case of the earlier dessert varieties well ripened for Scottish-grown fruit. Altogether we were well pleased with Duns Horticultural Show, and gladly record the fact that the committee and exhibitors exerted themselves to good purpose, well deserving the success their venture apparently enjoyed.

Royal Caledonian Horticultural Society.

(Continued from page 688.)

of Mrs. John Laing won in the pink class, and Messrs. Croll's Frau Karl Druschkis were adjudged the best whites.

Twenty-four blooms of roses formed the leading class for the Queen of Flowers, in the gardeners and amateurs' section, and some good blooms were staged. Mr. J. Simpson, gardener to the Earl of Dalhousie, Panmure Gardens, Carnoustie, was first prize-winner, and his exhibit was very creditable. Mdme. Melanie Soupert, Ethel Malcolm, Mildred Grant, and Avoca were a few names of varieties shown. Mrs. Russell, Rosegarth, Newton Mearns, was awarded second prize. Suzanne, Marie Rodocanachie, and Caroline Testout being among the best blooms. Mr. Lawrence Black, Kingslassie, Fife, was third. Mr. Simpson scored another success for twelve blooms, Mr. W. Lockhart, Rubislaw, Aberdeen, taking second prize, whilst for twelve teas the chief winner was Mr. W. Young, Kirkcowan.

A great deal of interest was taken in the class for a decorative display of roses, occupying 15ft. by 5ft. of staging. Three entries were staged, Messrs. J. Fairley and Co., Cairney Hill, Fifeshire, taking premier award. They had Rayon d'Or, good in colour; Lady Alice Stanley, Earl of Warwick, Duchess of Wellington, Mrs. A. Munt, Pharisaer, and a host of other good autumnal roses. Mr. R. C. Ferguson, Dunfermline, was awarded second prize for a bold display, in which Frau Karl Druschki was prominent, with Mrs. J. Laing, and such things as La Tosca, Duchess of Wellington, and Chas. J. Graham. Mr. W. Ferguson, Dunfermline, received third prize, his also being a very pleasing exhibit for September. Mr. J. Wilson, gardener to Sir John Gilmour, Bart., Montrave, Leven, put up six good bunches of rambler roses, winning first prize; White Dorothy was well shown. Mrs. Russell came second. Single vases of roses in separate colours made a big show, but limits of space forbid details.

SWEET PEAS.

These made a wonderful show, and there was much enthusiasm in evidence on account of the competition for the National Sweet Pea Society's Scottish Challenge Cup for twelve vases. Some splendid exhibits were staged in this class, and the fortunate winner of first prize and cup was Mr. John Petrie, gardener to Sir Thos. Burnett, Bart., Crathes Castle, Aberdeen. He showed Agricola, Edrom Beauty, Nubian, Clara Curtis, Mrs. C. W. Breadmore, Thos. Stevenson, Lavender Geo. Herbert, Melba, Rosabelle, Lady Miller, Etta Dyke, and Sunproof Crimson. All the flowers were good, and stood on Ross, Comrie, took second prize with quite a good lot of flowers, the third prize going to Mr. Thos. M. Kirkwood, Crieff. There were five competitors. Another class for twelve vases found Mr. John Petrie again to the fore. Dobbie's Cream, Inspector, Elsie Herbert, and Rosabelle were good, R. F. Felton also being very attractive. Second prize went to Mr. John R. Paterson, Beild Farm, Gargunnock, Stirlingshire, who had lost a little in the matter of staging. Third prize went to Mr. John Loan, Boughtrig, Coldstream.

VEGETABLES.

The collections of eighteen dishes of vegetables were a grand lot. There were three entries, and there was really but little between them, although we quite agreed with the judges' award, which gave first prize to Mr. Robert Stuart, gardener to Viscount Maitland, Thirlestane Castle Gardens. Mr. Stuart had some very fine onions, beautifully blanched leeks, Cramond Blossom potatoes as fine and even as could be, Golden Ball turnips, excellent cucumbers, and long, clean parsnips. He also had peas, dwarf beans, tomatoes, beetroot, and celery. All the vegetables were of good types, and the staging was well done. Mr. Wm. Young, Kirkcowan, was awarded second prize, his onions and carrots being very good models. Snowball potato and The Provost were good dishes, and cauliflowers and celery were fine. Third prize was awarded Mr. Wm. G. Wadde, gardener to Lord O'Neill, Thanes Castle, Antrim, whom we may certainly congratulate upon an excellent exhibit, although placed last on the list.

In another class for twelve dishes, we found some extremely good produce, especially in the first-prize exhibit staged by Mr. Chas. Shaw, gardener to S. Mitchell, Esq., Kippen. Ailsa Craig onions were perfect specimens; Tender and True parsnips, New Intermediate carrots, and Perfection tomatoes were all grand, and the celery was splendidly grown. Mr. John Miller, The Reformatory, Stranraer, was second with another excellent exhibit, the weakest point, we thought, being some rather coarse cauliflowers. Mr. Samuel Gordon, Monreith, Wigtownshire, was third-prize winner, there being seven entries. Onions were extensively shown, some of the bulbs being of great size. Mr. Robert Watson, Thorncombe Park, Surrey, was first-prize winner for twelve bulbs. Mr. Robert Stuart, Thirlestane Castle Gardens, showed six remarkably fine leeks, for which he received first prize against severe competition, and in the potato classes also there were some splendid tubers. The twelve varieties shown by Mr. J. M. Stewart, Castle Douglas, were really splendid, and the second prize lot, shown by Mr. J. Kidd, almost equalled them.

[We regret that limits of space compel us to hold over our report of the non-competitive exhibits until the next issue.]

Eucalyptus cordata. — Small seedlings of this Australian Gum Tree form very pleasing dot plants in some of the arrangements of summer bedding. Secured to an upright stick, from 3ft. to 4ft. high, they branch out freely and regularly, and the heart-shaped leaves of a markedly glaucous tint are very attractive.—W.

THE 1913 BULB BOOK

A descriptive List of every hardy Bulb worth growing.

LILIES,

PRACTICAL GUIDANCE IN GARDENING.—Complete catalogue of Books on all Phases of Horticulture will be sent POST FREE upon application to the Publisher of THE GARDENERS' MAGAZINE, 148-9, Aldersgate Street, London, E.C.

ANSWERS TO CORRESPONDENTS.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of THE GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in THE GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

SEEDLING CARNATION. — T. H., Surrey: I am sending herewith flowers of a seedling border carnation, and I should like to have your opinion as to whether it is worth propagating. It was given to me by a friend, who raised it from seed, and has propagated a good stock of it.—The carnation possesses merit, but basing our opinion on the flower before us, it is not sufficiently meritorious to receive a distinctive name and be introduced into commerce. It may, of course, possess the attributes of great freedom of flowering, fine habit, and calyces that do not split; but without some knowledge of these important characteristics it is not possible to formulate a definite opinion of the value of the variety. You would certainly not err greatly in raising a stock and growing it next year under conditions that will enable the variety to attain full development.

DIPLOMA OF GARDENING.—A Young Gardener: Being in agreement with those who consider that gardeners should have an opportunity of obtaining a diploma showing that they possess a knowledge of both the practical and scientific sides of gardening, I was much interested in the particulars you recently gave of the scheme that has been prepared by the Royal Horticultural Society for granting the National Diploma in Gardening. The scheme is doubtless a good one, but it appears to me that the fees for examination are unnecessarily high. Is that not your opinion?—There is no doubt that the payment of £1 for the preliminary examination and £3 for the final will be a tax upon the resources of some of those who may wish to take part in the two examinations, but the tax will not be so heavy as to prevent those who are in earnest doing so. It should be remembered that the examinations will be conducted in the interest of those who are anxious to obtain the diploma rather than in that of the Royal Horticultural Society, and that examinations, more particularly those of a high class, cost money. We would strongly advise you not to allow the fees to prevent your entering the examinations, but to set vigorously to work to so thoroughly prepare yourself as to be able to pass them.

THE TIGER FLOWER.—J. H., Caerphilly: Could you kindly identify the enclosed plant for me? It is difficult for me to send you a flower, as it only lasts a day. It opens in the morning, and towards evening fades away. But I am sending you a flower-stalk showing you its habit. The petals of the flower will have faded before it reaches you, unfortunately. There are three large petals and three smaller ones occupying the spaces between the larger ones. When open the flower is like a gorgeous orchid—of a beautiful orange suffused crimson tint with irregular rich crimson blotches. I enclose sketches of the petals nearly exact size. You will notice three or four flowers issue from the same sheath. They appear in rotation—one one day and the other the next, and so on. It is a bulbous plant, with bulbs a little smaller than Mrs. Langtry narcissus. They were given me by a friend last winter. I planted them in April. He tells me to lift them when thoroughly ripe, about Christmas time, and store them, as they are liable to rot away if left in the ground. The only name he knew for them was the Welsh name, Glaswellyn or grass flower—the plant referred to in the Psalms in the verse, "Like as grass are men's days." Is he correct, and if so, what is the botanical name? I have just spent a fortnight at Kew, but I failed to see the plant there. Trusting you will be able to find its name, or suggest what it might be.—After a careful examination of the rough sketches you have sent us, we have no doubt that your plant is Tigridia pavonia conchiflora, commonly known as the Peacock Tiger Flower. As you have been advised, it is necessary to lift the bulbs in the autumn, store them for the winter in some place where they will be safe from the frost, and replant in the spring. We do not know the tigridia under the name of Glaswellyn or Grass Flower, and, as the whole of the species are natives of South America, one of them could hardly have been used in the Psalms as illustrative of the duration of the life of man.

REPLANTING SEEDLING ROSES. — E. G., Crewe: I am writing to ask you to tell me, through THE GARDENERS' MAGAZINE, when would be the best time to remove seedling roses. I have some in the open ground, and some are in a box among other plants. When do you think would be the most desirable time to pot them? They are this year's seedlings.—The seedling plants in the box might with advantage be potted off singly at once. By putting them into pots now they will have time to become nicely rooted by the winter, and will be in a better condition to make a strong growth in the spring than would be the case were they to remain undisturbed until a later period. When repotted they should for a time be kept rather close and moist to assist them to make new roots quickly. The seedlings in the open are, we assume, growing more freely than are those in the box, and it might be well to leave them undisturbed until the end of October or early in November, and then lift and put into pots.

FRUITING OF DOUBLE-FLOWERED PEACHES.—"X.": Can anyone tell me why the double peaches in my garden—not of an edible variety—produce fruit each year, whereas the single-flowered varieties never show a fruit?—As a rule the ornamental peaches with double flowers produce fruit much less freely than do those with flowers that are single, and your experience is quite exceptional. In the case of these peaches the doubling is not carried so far as to practically suppress the organs of fructification, and it is not difficult to assume that the central florets protect both anthers and stigma from the injurious effects of frosts and cold winds. In the single flowers the petals, when the flowers have expanded, are arranged somewhat horizontally, and leave the central organs fully exposed to the effects of unfavourable weather. Possibly some of our readers may be in a position to throw further light upon what is really a question of considerable practical importance.

NAMES OF PLANTS.

W. R., Cheshire.—Ulmus campestris stricta.

A. WILSON, Norton.—1, Vitis hetrophylla; 2, Polygonum baldschuanicum; 3, Sedum kamschaticum.

J. F. C.—1, Chelone obliqua; 2, Sedum Ewersi; 3, not recognised from the specimen; 4, Sempervivum hirtum, hardy on dry, sunny nooks of the rockery:

D. B. W., Wellingborough.—The cattleya appears to differ but little, if at all, from C. guttata, but the flowers had necessarily lost some of their freshness in passing through the post. We should very much doubt Odontoglossum crispum being one of the parents, and we do not recognise it as one of the hybrids of O. Edwardsi with which we are acquainted.

F. K., Beds.—As we have frequently stated, we cannot undertake to name florists' flowers. The flowers invariably lose much of their colour in the course of transit through the post, and frequently they fall to pieces on the way. In the case of the phloxes you have sent, many of the flowers had fallen, and the other had so changed in colour as to render recognition impossible.

OBITUARY.

MR. WILLIAM BULL.

We much regret to learn of the death of Mr. William Bull, elder son of the late Mr. William Bull, of Chelsea. Mr. W. Bull was forty-six years of age, and was associated with the business now carried on by his brother, until four years ago, when ill-health compelled him to retire. Mr. W. Bull was well known to a wide circle of horticultural friends, who will mourn their loss.

MR. ROBERT MACK.

Mr. Robt. Mack, J.P., of Messrs. Mack and Miln, Darlington, died at Catterick Bridge on September 1, at the age of 57. He entered the nursery business at a fairly early age, and in 1897 was joined by Mr. T. E. Miln, and founded the present firm. He was a well-known rose grower and judge of florists' flowers. He was a musician of exceptional ability, and for many years acted as organist at Catterick Church.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

The Planting Season of Bulbs.

Although the cultivation of the various classes of bulbous plants suitable for beautifying the flower garden, more especially during the spring season, has undergone a remarkable development within recent years, it cannot be said that their utilisation has been carried to an excess in either private or public gardens. Rather might it be suggested that, considering the wondrously beautiful effects which can with their aid be produced at a comparatively small cost, they should in many gardens be planted more freely than has yet been the case. By means of a comprehensive selection from the many kinds that have a place in trade catalogues, the flower garden might have its interest and attractions greatly enhanced throughout the whole year with the flowers of bulbous plants. The winter has not proceeded far on its course before the surface of shrubbery borders, and other spaces might be carpeted with the bright green leaves of the winter aconite, and these, in their turn, bespangled with the glistening yellow flowers. This firstling of the year is followed by the snowdrop, of which there are several fine forms, springing, it may be, from the green turf, or nestling in sheltered borders, the chionodoxas and the scillas in their various shades of blue, and very charming is the effect produced by them, whatever may be the position occupied. Not until the Scotch crocus yields of its richly-coloured flowers, and converts lawn or border into a veritable field of the cloth of gold, are the colour effects derived from the flowers of bulbous plants otherwise than quiet and pleasing. Then as the last of the golden flowers of the crocus pass away, worsted, as it were, in a competition for ascendancy with the rapidly-increasing sunlight, there is a great outburst of rich colouring produced by the flowers of the many fine crocuses that we owe to the Dutch florists. These, in their turn, are succeeded by the early-flowering tulips that also had their origin in the Netherlands, and for fully two months the owners of gardens will enjoy a series of glorious effects produced by these bulbs, provided he is careful to include in his selection some of the best of the Darwins, and of the varieties that found shelter in English cottage gardens during the period when they were banished from great gardens to make way for tender summer bedders. During a similar period, also, the attractions of the garden may be maintained with the aid of narcissi alone, for there are more than sufficient among the inexpensive varieties to render this easy of accomplishment. But the production of spring displays with either class is not advisable, for not only is it possible to produce more tasteful effects by a combination of both daffodils and tulips in a colour scheme, but the interest of the flower garden which contributes so greatly to its enjoyment is materially enhanced thereby. Concurrently with the flowering of the narcissi and tulips, hyacinths in a great diversity of colouring yield of their floral wealth, and contribute freely to the charm of both bed and border. During the summer months the lilies are in the ascendent, and will, with judicious selection and careful cultivation, give a succession of flowers from quite early in the summer until the autumn, when they will be supplemented by the gladioli, montbretias, and other classes of bulbs that bloom from the closing days of summer onwards. To refer otherwise than in this brief manner to the aid the bulbous plants are able to render in maintaining the attractiveness of the flower garden during the greater part of the year would require much space, and for the present it will suffice to suggest that they should, as a class, be carefully studied by those concerned with flower garden management, with a view to their fuller and more effective use. The matter of the greatest interest at the present time is the selection and planting of the various kinds that bloom during the spring months, and the key-note to success is, perhaps, the purchase of bulbs and planting them at the earliest moment. None of the early-flowering bulbs are improved by being kept out of the ground after this date, but they may rapidly deteriorate, and fail to produce flowers of high quality. Some of the daffodils will bloom satisfactorily planted at Christmas, while others will fail to do so, or produce flowers of very poor quality, when the planting is deferred until after November. Such early-flowering subjects as the crocuses, chionodoxas, scillas, and snowdrops, fail to bloom satisfactorily when the planting is delayed until quite late in the autumn. Another point of importance is to recognise the fact that, while the embryo flowers were formed before the bulbs were lifted in the summer, a rather liberal amount of nutrient matter in the soil is essential to their full development. Heavy manuring is in no case essential, or even desirable, but the soil should be moderately rich, and a light dressing of superphosphate of lime or bone meal applied previous to digging will be of immense value if the ground is impoverished. The flowers of daffodils and tulips are invariably in much request for the embellishment of indoor apartments, and we would strongly advise that, instead of depending for supplies upon the plants forming part of colour schemes in the

MR. J. JEFFREY.

flower garden, a breadth consisting of the most useful varieties be planted in the kitchen garden for the purpose of furnishing cut flowers. A convenient border devoted to the choice May-flowering tulips would afford much interest. It would be of great educational value, and the institution of comparisons between the shape and colouring of the flowers of the varieties included in the selection would be found very pleasant entertainment to those owners of gardens who appreciate the charms of individuality in the flowers that have a place in their gardens. With the bulbs should invariably be associated dwarf-growing, fibrous-rooted plants that bloom in spring. The effect is greatly enhanced by the combination, and the latter serve the purpose of carpeting the surface with green or grey foliage during the winter months, and by maintaining a display of flowers after the bulbs have passed out of bloom they render it unnecessary to clear the beds until the growth of the latter has made sufficient progress to admit of their being lifted with safety. In small gardens it will be advisable not to trouble much about the preservation of the bulbs, but to plant inexpensive varieties, and clear the bulbs away immediately preparation has to be made for the summer flowers. When fibrous-rooted plants are used it is necessary to select them with due regard to harmony of colours, and to allow rather more space between the bulbs than when the latter are the sole occupants of the area.

Mr. J. Jeffrey is, perhaps, best known to our readers in connection with his association for many years in the conduct of the gardens at Harewood House, the residence of the Earl and Countess of Harewood. At Harewood Mr. Jeffrey had charge of about 150 acres of garden, pleasure grounds, and ornamental plantataions, and was very successful in flower gardening and fruit culture, his skill and judgment enabling him to maintain the position of the place among the great gardens of the country. Several years ago Mr. Jeffrey took charge of the gardens at St. Mary's Isle, Kirkcudbrightshire, where he still acts as head gardener to Captain J. Hope. Here, in an unusually favoured spot, many of the choicest trees and shrubs flourish in a manner that suggests the climate of Cornwall, South Wales, or some parts of Ireland, rather than Scotland. Close to the Solway, and in a position where the influence of the Gulf Stream is felt in a remarkable manner, St. Mary's Isle enjoys a mild climate. Here Mr. Jeffrey finds ample scope for his skill and wide knowledge, and has under his charge a splendid collection of rare and interesting plants, which make St. Mary's Isle one of the most attractive places in the South-west of Scotland.

Destruction of White Butterflies.—In an interesting note referring to the endeavour that is being made in Surrey to reduce the numbers of the white cabbage butterfly, whose caterpillars are so destructive to green vegetables, the "Pall Mall Gazette" observes: "Allotment holders at Farncombe, Surrey, are destroying white butterflies by the thousand on the ground that they injure vegetables and greenstuffs. Of course, their caterpillars do. And butterflies do something worse than devastate allotments—they are capable of conveying diseases. At Quetta it was found that they were as effective as any rat in spreading plague. On the other hand, it is always dangerous to go to extremes in slaughtering a particular animal, because of that wonderful law of balance in Nature, by which each animal does some work at any rate in keeping down the undue increase of another. Exterminate the owls and you bring upon your fields a plague of mice. Exterminate the birds and your fields and orchards are visited with pernicious insects. Sweep every locust off the Argentine plains and the alfalfa or lucerne rapidly deteriorates. It is rather dangerous, then, to make a too complete holocaust even of the white butterfly. They have their appointed work, which doesn't get done if their numbers are too cruelly thinned." We appreciate what our contemporary says with regard to the destruction of owls and other birds, and are in agreement with what is said with reference to their utility in assisting to maintain a balance in nature. We should have been glad had the writer gone a little farther, and stated what the "appointed work" of the white cabbage butterfly is under the existing conditions that obtain in this country.

Althorp Park, Northampton, the beautiful Midland seat of Earl Spencer, is of special interest for the moment because his Majesty King George is staying there for the Army manœuvres. For over three centuries the Spencer family have planted new trees and cared for the old ones in their fine estate, and many members of the family have been keen gardeners. A fine Wellingtonia, planted in 1863 by King Edward VII., when Prince of Wales, was 40ft. high ten years ago. We have on several occasions referred to the work done at Althorp Park, and in our issue of July 25, 1903, we published an illustrated descriptive account of the beautiful gardens there.

Attractions at Kew. —Although autumn weather is with us, the floral attractions at Kew are very considerable just now. Besides the summer bedding display along the Broad Walk and in front of the Palm House, there are the hardy hibiscus in the Berberis Dell, water lilies in several parts of the garden, Hydrangea paniculata massed in the pleasure grounds, tritomas near the Orchid Houses, heaths near the Succulent House and in the Arboretum, hardy cyclamen near the Cumberland Gate, helianthuses and Michaelmas daisies in many places, and a brave display of flowers in the herbaceous border of the T-range. Here and there among the trees there are early signs of autumn colouring, and under the glass there are many interesting and showy subjects in flower.

Scientific Investigation of the Soil.—Professor Wood, in his presidential address at the opening meeting of the Agricultural Section of the British Association, gave a general survey of the progress of agricultural research, and, with reference to the scientific investigation of the soil to which we have directed special attention, said that during the last twenty years there had been a wonderful advance in soil science. Our knowledge of nitrification and ammoniacal fermentation had been much extended. The part played by the nodule organisms of the leguminosæ had been well worked out, but the greatest advance had been the discovery of the part played by protozoa in the inhibition of fertility. Russell and Hutchinson, at Rothamsted, observed that the fertility of certain soils which had become sterile was at once restored by partial sterilisation, either by heating to a temperature below 100 degrees C., or by the use of volatile antiseptics, such as toluene. This observation suggested that the factor causing sterility in these cases was biological in nature, that it consisted, in fact, of some kind of organism inimical to the useful fermentation bacteria, and more easily killed than they are by heat or antiseptics. After a long series of admirable scientific investigations these workers and their colleagues had shown that soils contained many species of protozoa, which preyed upon the soil bacteria, whose numbers they kept within definite limits. Under certain circumstances, such, for instance, as those existing in the soil of sewage farms, and in the artificial soils used for the cultivation of cucumbers, tomatoes, etc., under glass, the protozoa increased so that the bacteria were reduced below the numbers requisite to decompose the organic matter in the soil into substances suitable for absorption by the roots of the crop. Practical trials of heating such soils, or subjecting them to the action of toluene, or other volatile antiseptics, had shown that their lost efficiency could thus be easily restored, and the method was now rapidly spreading among the market gardeners of the Lea Valley. The constant renewal of expensively-prepared soil which becomes "sick" in the course of a year or so was a serious item in the cost of growing cucumbers and tomatoes. It could now be restored to fertility by partial sterilisation at a fraction of the cost of renewal, and considerable sums were thus saved by the Lea Valley growers.

Sweet Pea Annual Meeting and Conference. — The National Sweet Pea Society will hold its annual general meeting at the Hotel Windsor, Victoria Street, Westminster, at 2.30 p.m., on Monday, October 20, 1913. At 7 p.m. a conference will be held at the Hotel Windsor, when Mr. J. S. Brunton will lecture on "The Sweet Pea Industry." For the convenience of members attending these meetings a dinner has been arranged for 6 p.m. Applications for dinner tickets (5s. each, exclusive of wines) must be made to the Hon. Secretary, Mr. Charles H. Curtis, Adelaide Road, Brentford, on or before October 18.

Prize Potato Crops.—In the spring 28lbs. of seed potatoes were distributed amongst members of the Horsmonden (Kent) Gardeners' Society, and prizes were offered for the gardeners who grew the greatest weight of potatoes from a pound of seed. The first prize winner produced 50lbs. 13ozs. from his pound, the second having 43lbs. 7ozs., the third 39lbs. The average was 22lbs. yield per lb. The results are interesting, but the crops are very small as compared with those previously obtained in competitions for prizes for the heaviest crops from 1lb. of seed tubers.

Presentations to Mr. J. Harrison Dick.—Mr. J. Harrison Dick, who has for several years past been Editor of the "Journal of Horticulture," and was formerly on the staff of the "Gardening World," is shortly leaving England to try his luck in the United States, where already a number of British horticultural journalists have made a home for themselves. In view of his departure, the members of the horticultural press invited Mr. J. Harrison Dick to meet them at the Horticultural Club on Thursday evening, September 11, when, on their behalf, Mr. George Gordon, V.M.H., presented Mr. Dick with a handsome gold watch and address, subscribed for by themselves, and wished him good health and prosperity in his new venture. On the previous Monday evening the officers and committee of the United Horticultural Benefit and Provident Society presented Mr. J. H. Dick, their vice-chairman, with a gold-mounted fountain-pen and a morocco-bound address as a token of their esteem, coupling these with all good wishes

Mr. Dick leaves for the United States at the end of the month, and is at present enjoying a short Continental trip. He is succeeded in the editorial chair of the "Journal of Horticulture," by Mr. Horace J. Wright, who, under a previous proprietor, occupied a similar position.

Suggested Scottish Garden of Hardy Plants.—Speaking the other day at Glasgow, Sir John Stirling Maxwell urged that in the West of Scotland they should have a garden of hardy trees, plants, and shrubs worthy of their unrivalled soil and climate. Such a garden would be better than anything which now existed in the world; far better than the botanical gardens in this country, which, unfortunately, did not always lie in good situations for the cultivation of many kinds of hardy plants. Glasgow possessed an unequalled site for such a garden in the Highland property which the generosity and foresight of Lord Rowallan had given to the city.

Window Plants at Preston.—Early in the summer we made reference to the strenuous endeavour that was then being made by the Preston Horticultural Society for the purpose of encouraging window gardening in the town. We have now much satisfaction in recording the fact that the efforts made have been highly successful. This was, in some measure, indicated by the number of entries in the window-box competition provided at the society's recent autumn show, but the best proof has, of course, been the increased floral attractions of the dwellings, more especially of those of the middle and working classes. There were 158 entries in the classes for window boxes, and 368 window plants were staged, as compared with eighty at the corresponding exhibition held last year. The children also exhibited more largely than in previous years, the plants contributed by them numbering 2,000. These, it should be mentioned, were distributed among the children in the spring by the Corporation of the town.

Winter Garden and Estate for Worthing.—We understand that after a long sitting a few days ago, the Worthing Town Council decided, by twenty-one votes to five, to purchase the Beach House Estate for the site of a winter garden and other purposes. The estate was the property of the late Dowager Lady Loder, and the purchase price is £20,000.

Sweet Pea Trials for 1914.—The committee of the National Sweet Pea Society will hold trials of sweet peas at the Burbage Experiment Station, Leicestershire, conducted by Major C. C. Hurst, F.L.S., in 1914. No certificates or awards will be granted to novelties unless they are sent for trial. For the novelty trials a charge of 2s. 6d. per variety will be made, and novelties will be accepted only from the raiser or introducer. As all the trials will be sown this autumn, thirty seeds of each novelty must reach the Hon. Secretary, Mr. C. H. Curtis, Adelaide Road, Brentford, Middlesex, not later than Saturday, October 4, 1913. The seeds must be placed in plain packets, but each packet must bear a number or letter for purposes of identification. With the seeds there must be a letter bearing the sender's name at the top, the number or letter of each novelty sent, and opposite such letter or number the name of the variety (if any), the colour section to which it belongs, and, if orange or salmon, whether it should be shaded. Sweet peas will also be tested for purity at a charge of 10s. per stock, or variety, sent. Not fewer than two dozen seeds should be sent. In every case the amount due for trials charges must accompany the seeds. Every sender will receive the report of the Floral Committee in the autumn of 1914.

Alpine Plants in Town Gardens.—In the course of an interesting lecture on plant hunting in the Swiss Alps, given before the Royal Photographic Society, Mr. R. A. Malby stated that half the alpine plants he collected grew admirably in his suburban garden, one quarter just existed, and the other quarter were unable to live under the conditions that obtained. Mr. Malby referred to the wealth of flowers that may be found just below the snow line, and suggested that the best time to visit Switzerland for the purpose of finding the plants growing at high altitudes is at the end of June and early in July.

Gardens of the City of London.—The City garden described and illustrated in the "City Press" of the 13th inst., is that of St. Botolph's Churchyard, Aldersgate, which skirts Little Britain, and forms so delightful a setting to the northern facade of the Post Office buildings in St. Martins-le-Grand. This garden is described as one of the most beautiful, as well as being the largest, garden within the City boundary, and the account of its characteristic features, and the steps that were taken to secure the fine old churchyard for public use as a restful resort is highly interesting. The illustration shows the eastern end, and includes the fountain and fishpond, not the least delightful of the features of this restful beauty spot.

Scholarships in Gardening.—Through the Worshipful Company of Gardeners Mr. Blades, the ex-Master, has placed a substantial sum at the disposal of the Board of Agriculture for the establishment of scholarships in gardening, or the promotion of technical training in horticulture.

Registration of Orchid Hybrids. — The recommendation of the Orchid Committee of the Royal Horticultural Society that a new record, to be called the Hybrid Orchid Register, be established, has been adopted by the Council. The recommendation of the committee was published in our issue of the 13th inst.

EXPORTATION OF PLANTS.

Issue of Certificates.

With a view to assist nurserymen in England and Wales to develop their export trade, the Board of Agriculture and Fisheries are prepared to issue the Certificates required by the Governments of the countries and colonies to which plants are to be exported, under the following conditions:

1. In cases in which consignments of plants or bulbs are only admitted on production of a Certificate by the Board, or by one of their Inspectors, that the contents have been examined and declared to be healthy or free from certain specified pests, application should be made to the Board a few days before the consignment is to be dispatched. If it is desired that the plants should be sent by parcel post they should be sent ready packed in a box, with the lid not nailed down, to the Secretary, Board of Agriculture and Fisheries, Craven House, Northumberland Avenue, London, W.C., marked on the outside, "Plants (or bulbs) for export." A prepaid adhesive label addressed to the consignee should be enclosed, and the Customs declaration form required by the Postal Regulations (Post Office Guide, p. 772) should be filled up and affixed to the box. The box will be dispatched by the Board and a receipt of posting obtained.

The necessary sum must also be enclosed if it is desired that the parcel should be insured, but it must be understood that the Board cannot, in any case, accept any responsibility for any loss or damage which may arise during the examination or transit of the goods.

No charge will be made for the examination of a consignment which is contained in one box and weighs when packed not more than 11lbs. For the examination of any consignment exceeding that weight, whether packed in two or more boxes, the following charge will be made: Packages not exceeding 56lbs. in weight, 2s. 6d. Packages weighing between 56lbs. and 1cwt., 5s. Packages weighing over 1cwt. cannot be examined at the Board's office, and a special fee will be charged for examining them. If the Inspector is required for any reason to travel more than 20 miles to the place where the consignment is to be examined, a fee of £2 2s. will be charged. The fee must in every case be paid before the Certificate can be issued.

2. The Board have made special arrangements to meet the requirements of the Regulations issued by the Government of the United States of America under the Plant Quarantine Act of 1912. These Regulations require, among other things, that nursery stock shipped between October 1 and May 31 shall be inspected on or after October 1, and that such stock, if shipped during the growing season, shall be examined at the time of packing. The inspection is required to be carried out under the direction of a duly authorised official of the board, and the plants must be accompanied by a Certificate of that official as to their freedom from injurious plant diseases and insect pests.

An original Certificate must accompany the invoice of each consignment, and a signed copy must be attached to each "container." Exporters when applying for the Certificate should therefore state how many copies will be required by them.

Growers who propose to export plants to the United States should inform the Board of their intention as early in the year as possible. Preliminary inspections will be made from time to time during the summer months, and a final examination will be made as early as possible in October.

Applicants must furnish the Board with a written undertaking that no plants will be shipped under their Certificate except those actually grown on the premises referred to in the Certificate.

After the final examination has been made and if the nursery is found to be free from injurious plant disease and insect pests, the Board will be prepared to issue such Certificates and copies as may be required up to May 31 in the following year.

The fee charged by the Board for these Certificates will in most cases be £2 2s. a year for each nursery, for which sum an unlimited number of Certificates and copies can be obtained.

The Board reserve the right of refusing to consider applications for inspection unless they are received before November 1, 1913.

Any stock shipped between May 31 and October 1 will be examined under the conditions explained in section 1 of this Memorandum.

N.B.—Nursery stock cannot be admitted into the United States unless a permit for the entry has been obtained from the Department of Agriculture, Washington. Shippers on this side, therefore, would be well advised to see that the necessary permit has been obtained by their customer before the goods are shipped. Entry will not be allowed, moreover, unless the case, box, or other container or covering is plainly and correctly marked to show the number of the permit, the general nature and quantity of the contents, the district or locality and country where grown, the name and address of the exporter, and the name and address of the consignee.

3. The Board are prepared to issue Phylloxera Certificates, when such certificates are required by the Government of the importing country, in the case of stock exported from nurseries which have been examined by their Inspectors. The fee for such examination will be £2 2s. per annum, but a separate fee will not be charged in this connection if the nursery has been inspected in accordance with the arrangement outlined in section 2.

4. In cases in which a Certificate of the Board is required stating that no disease of a certain kind has been reported from the neighbourhood in which the plants were grown a declaration signed (and in some cases sworn) by the grower must be sent, stating that the plants (in most cases potatoes) were grown on a particular farm.

In cases in which the Certificates required do not fall within any of the foregoing categories, nurserymen who wish to export plants should apply to the Board for further particulars. SYDNEY OLIVIER, Secretary.

Board of Agriculture and Fisheries,
4, Whitehall Place, London, S.W.

NATIONAL SWEET PEA SOCIETY.

I venture to address you to ask your support for the new constitution of the National Sweet Pea Society, which will shortly be submitted to your vote by that Society as having been put forward by me.

The chief objects of the proposed changes are to place the government of the society in the hands of independent amateurs, to reduce the number of "varieties" to a trustworthy and comparatively short list, and to control the introduction of alleged new varieties.

I need not enter into the past unhappy history of the society, or support my scheme by recrimination, because I claim that the proposed new constitution will benefit immensely both the public and the trade. The former will benefit because they will be protected against being asked to buy as novelties things that are not novelties, while the trader will be secured against the appropriation and re-naming in the future of anything good that he may have produced.

On the other hand, control, unless it is carefully considered, is apt to hinder enterprise, and I should myself be strongly against it, were it not for the principles involved, and my firm belief that an enlightened and comprehensive handling of the whole question must not only honour British horticulture, but bring profit to British trade.

It is inconceivable to me that any amateur member of the society should fail to support the new scheme, and if amateurs support it, its adoption is assured. I earnestly hope, in that case, that trade members, forgetting the past, will heartily support the society and guard their legitimate interests in the position of dignity and influence which will be open to them in the proposed advisory committee.

The trade have hitherto borne the heat and burden of the day. It is now for amateurs to come forward and take up the work. Great past experience is not essential, because all the alleged varieties will be grown side by side for comparison. This can easily be done on one-third of an acre. Will those who are willing to join the General Committee kindly inform me accordingly, as soon as they see the proposed rules, in order that matters may take shape at the annual meeting without undue loss of time? Many will join the society as soon as it is placed upon a new basis; but it devolves upon those who are now in it to bring about the change.

It is most important that the proposed rules should be accepted as they stand, because if members suggest modifications there will be endless confusion at the meeting, as this could not in any case deal with any important modification unless it had received the acceptance of a majority of members who desired to vote upon it. There will be opportunities later of considering any amendments that may then come forward.

Finally, I would ask every amateur who can to attend the annual meeting. It is hard to expect traders to carry through enthusiastically proposals which are of a nature that many of them have hitherto opposed.

Upton-on-Severn. HILDA HEMUS.

AWARDS TO ANTIRRHINUMS AT WISLEY.

The following awards have been made to antirrhinums at Wisley by the R.H.S. Floral Committee:

Award of Merit.—To (No. 3) Amber Queen, Messrs. Barr and Sons, Covent Garden; (No. 4), Amber Queen, Messrs. Watkins and Simpson; (No. 12), Beacon, Messrs. J. Veitch and Sons, Chelsea; (No. 13), Beauty, Messrs. Barr and Sons, Covent Garden; (No. 17), Bonfire, Messrs. Simpson, Birmingham; (No. 18), Bonfire, Robert Sydenham Limited, Birmingham; (No. 37), Carmine Queen, Messrs. Watkins and Simpson; (No. 41), Coccinea, Messrs. Hurst and Son, Houndsditch; (No. 56), Crimson King, Messrs. Hurst and Son, Houndsditch; (No. 67), Daphne, Messrs. Hurst and Son, Houndsditch; (No. 69), Defiance, Messrs. R. H. Bath, Wisbech; (No. 80), Fire King, Messrs. R. H. Bath, Wisbech; (No. 89), Golden Morn, Messrs. Watkins and Simpson (No. 90), Golden Queen, Messrs. R. H. Bath; (No. 111), Moonlight, Messrs. Dobbie and Co., Edinburgh; (No. 104), Maize Queen, Messrs. Dobbie and Co.; (No. 122), Pink, Messrs. J. Veitch and Sons; (No. 135), Queen Victoria, Messrs. J. Veitch and Sons; (No. 149), Rosy Morn, Messrs. Watkins and Simpson; (No. 151), Salmon Pink, Messrs. J. Veitch and Son, Exeter; (No. 164), Sunset, Messrs. Dickson and Robinson, Manchester; (No. 178), White Beauty, Messrs. Dobbie and Co.; (No. 182), White Queen, Messrs. Dobbie and Co., (No. 185), Yellow, Messrs. J. Veitch and Sons; (No. 186), Yellow King, Messrs. Barr and Sons; (No. 193), Yellow Queen, Messrs. Hurst and Son.

Highly Commended.—(No. 1), Albino, Mr. F. C. Heinemann, Erfurt; (No. 21), Brilliant, Messrs. Barr and Sons; (No. 24), Brilliant Rose, Messrs. R. H. Bath; (No. 30), Red Queen, Messrs. Watkins and Simpson; (No. 45), Coral Red, Messrs. J. Veitch and Sons; (No. 58), Dainty, Messrs. Dickson and Robinson; (No. 63), Dainty Queen, Robert Sydenham Limited; (No. 82), Firelight, Messrs. R. H. Bath; (No. 83), Galatea, Messrs. Barr and Sons; (No. 112), Nobile, Messrs. Hurst and Son; (No. 126), Pink Beauty, Messrs. Watkins and Simpson; (No. 128), Pink Queen, Messrs. Watkins and Simpson; (No. 145), Roseum, Messrs. J. Carter and Co., Raynes Park; (No. 156), Scarlet Carmine, Messrs. Dickson and Robinson; (No. 183), White Queen, Messrs. Hurst and Son; (No. 189), Yellow Prince, Messrs. Hurst and Son.

SUMMER FLOWERS AT THE ZOOLOGICAL GARDENS.

To the uninitiated the name of the Zoo suggests exotic animals rather than exotic plants, yet for some time the Zoo has justly had a good reputation for the quality of its summer bedding. This year the reputation is well upheld, and many bright and pleasing features, in addition to well-thought-out combinations, may be found there.

The main points in which the greatest attention is devoted to bedding plants are the open space in front of the monkey-house, and the neighbourhood of the refreshment-rooms, though many other bright little spots, both of tender bedding plants and of hardy herbaceous subjects, are to be met with. In front of the monkey-house the bedding is of a decidedly formal character, but at the same time remarkably effective. The forms of Celosia pyramidalis, for which the Zoo has long been famous, are up to the best standards, and of other subjects with which the mixed beds are filled special mention may be made of bronze pelargoniums, now not much used; the variety Black Vesuvius, which is, from a foliage point of view, quite a nigger in its way; the scarlet Paul Crampel, fuchsias, bedding violas, and numerous other subjects. As dot plants, Eucalyptus cordata is in this section freely used, and very effective it is for this purpose. A background of taller subjects, in which hollyhocks predominate, complete this picture. In the neighbourhood of the refreshment rooms the bedding is of a less formal nature, but equally delightful. The beds are there scattered about over beautifully-kept turf, their attractiveness being enhanced by the handsome shrubs with which they are surrounded. Some of the combinations here are very striking, such as a bed of Miss Willmott verbena, overtopped by finely-flowered heliotropes, and edged with Fuchsia Golden Treasure. Another has salmon-coloured clarkias dotted over a groundwork of purple viola. One that arrests attention by reason of its uncommon features is planted with the pink-flowered Pelargonium Constance and Fuchsia Abd-el-Kader, above which are the feathery plumes of Humea elegans, the whole being edged with the silvery-white variegated Euonymus japonicus latifolius albus, with an extreme margin of thrift, which, though out of bloom, is decidedly effective for this purpose.

An uncommon but pretty bedding pelargonium is the dwarf single-flowered Violet Hill, over which are dotted plants of Leucophyta Brownei, the whole being edged with Koniga maritima.

Many more examples might be given did space allow, but enough has been mentioned

CACTUS DAHLIA DOROTHY HAWES.

Rich rose colour. F.C.C., and Gold Medal, N.D.S., September 9. Messrs. J. Stredwick and Son, St. Leonards-on-Sea.

(See page 712.)

to show the beauty and pleasing variety of the arrangements. In another part of the gardens was noted an unusual combination, namely, a bed of the scarlet lobelia and Leucophyta Brownei, edged with the golden-leaved Pelargonium Creed's Seedling, which in the older days of bedding used to be largely grown, but is now not often met with.

Fuchsias, of course, contribute their share to the floral display, among the varieties being the bold-growing, red-flowered Abd-el-Kader; Lye's Own, a light variety; Ballet Girl, double white; Crimson Glow, a bright-coloured kind, remarkably free flowering; Gertrude Pearson, a particularly good-shaped, dark-coloured flower; and the various tinted-leaved kinds, such as gracilis variegata, Sunray, and Golden Treasure.

A bed of a bright mauve-coloured viola, dotted over with standard plants of the silvery variegated Veronica Andersoni variegata, is very pleasing and unusual.

Briefly it may be said that, apart from any other consideration, many useful hints may be picked up by a visit to the Zoo.

W. T.

RASPBERRIES.

It is in seasons of scarcity that the grower of bush fruits generally reaps the benefits of enhanced prices. Especially is this the case during such periods when crops have suffered more or less severely from late frosts. Supplies are then at a comparatively low ebb, and it is not at all unusual for retailers to sell such fruit as black currants at as much as 6d. per lb. In other seasons, when bumper crops are produced, it is, unfortunately, true that the market prices of the produce dwindles as the supply increases, and when the inevitable glut occurs there is a large amount of fruit on the grower's hands which it scarcely pays him to pick. Seldom does the public demand for bush fruits, such as raspberries, gooseberries, black, red, and white currants show any great variation from season to season, so this is an influence that needs but small attention from the grower. New kinds of bush fruits have, of course, made their appearance from time to time, notably the loganberry, and various nurserymen have succeeded in producing some very good hybrid fruits which not unlikely will become well established in orchards and market gardens in the future.

The raspberry crop is usually considered of first importance in the list of bush fruits. On small holdings there is no more profitable crop, especially if the soil is naturally suited to this fruit, in which case it will be a retentive loam that is moist and cool in summer. In the case of market cultivation the grower needs to exercise some care in choosing the varieties of raspberries he shall grow. Not every kind is suitable for this special purpose, but only a few, and it is in this respect that the raspberry crop resembles the strawberry, since there are but a few kinds of the latter that find favour with market growers. Such kinds as Abundance, a strong grower and large cropping kind, largely grown in Lincolnshire; Baumforth's Seedling, Carter's Prolific, New Red Superlative, and Laxton's Bountiful are all good market sorts. The last-named, by the way, is a new variety that has all the vigour of a seedling, and the cane is strong and vigorous, and entirely self-supporting.

In large centres the average price of raspberries is 4d. per lb., packed in chips for market, or about £24 per ton packed in pods for jam making; but, of course, these prices are very much subject to fluctuation, and, in some seasons, as much as £40 per ton may be asked, and paid, for the fruit, as at Blairgowrie this season, while in certain districts good quality fruit need not be retailed at anything less than 6d. per lb. Those to whom raspberry culture appears to be a profitable venture, and one in which they are contemplating making a start, should bear in mind a few important facts.

In the first place, the ground should be prepared for this crop as early in the autumn as possible, for it is observed that unless the canes become thoroughly well established before the winter sets in, they will throw suckers very sparingly in the following year, and so very little dependence can be placed on the first season's fruiting. Always select vigorous-rooting canes from good ground, and never those which show little, if any, fibrous root development. The latter, by the way, are often worked up into bundles and sold at a very low rate, but it is best to avoid them altogether, for they are very frequently merely the refuse, as it were, of old plantations that are being cleared out. Good quality canes can usually be purchased at about 3s. per dozen, or 20s. per hundred, but make sure they come direct from the ground, and have not been allowed to lie about with their roots exposed during frosty weather. If canes have been injured by frost in this way they will not easily start into growth after planting; and even if they do so the canes will probably produce only a very few weak and miserable shoots, of scarcely any good at all. It is not an uncommon practice among some growers to grade the canes, the strongest-looking ones being known as of first quality, and the others as second quality. Not infrequently, however, it happens that the second quality canes are really the best.

New raspberry canes are usually planted at from twelve to twenty-four inches apart, in rows five feet asunder, although, of course, a great deal depends on the richness of the soil and the variety that is being planted. On the above system of planting, however, it is evident that the space between the rows gives room for a crop of potatoes, or other suitable subjects, to be grown during the first season. Not only does the intercrop yield a very fair return, but it also assists in keeping the ground clear of weeds between the rows, which is a great consideration, by the way.

In the first year of growth the canes are kept cut back hard to about ten or twelve inches above the surface of the ground, which will cause them to make fresh shoots from the base for the following year's crop, and will also have the extremely beneficial effect of stimulating a healthy, fibrous root action, which is a very important factor in the production of fruit. Provided that good strong canes were planted fairly early, say, not later than October, there will, in all probability be a fair amount of young growth in the first year, and it will be seen that the ground between the rows is being covered with a network of fine, fibrous roots, which, of course, do not afterwards admit of any planting being done between the rows. Subsequently, one has to provide sticks or wires as a support for the canes. In nurseries this item means a very considerable expense, and some growers have dispensed with the practice altogether on this account. As an alternative they adopt the system of pruning the canes rather hard to a distance of, say, three or three and a-half feet from the ground surface, which makes them self-supporting.

As against this practice, however, there are several growers of my acquaintance who are quite emphatic on the point that it pays them best to provide proper supports for their canes in the usual way. I am inclined to think they are right. Certainly when unsupported canes are pruned hard in the spring the winds and heavy rains that arrive just at the period when they are heavily laden very quickly spoil the quality of the fruit. Of course, one can bed down with straw between the rows, but experienced raspberry growers will know that this is not a very practicable suggestion, although it would certainly tend to keep the fruit free from grit and dirt.

After-cultivation of raspberries consists chiefly in keeping the space between the rows clear of weeds by surface cultivation, and also giving a generous mulching of farmyard manure early in spring, immediately after or before the setting of the fruit, that is to say, when the flowers are forming. Such dressings of manure are of no little assistance in stimulating and plumping up the fruit. Subsequently, as soon as the fruiting season is at an end, the old fruiting canes should be cut down close to the ground, the principal object in so doing being to admit as much light and air as possible to help in the ripening of the newly-formed shoots. Seeing that the fruit crop of the following year depends entirely upon the proper ripening or maturing of these shoots, it is easy to see how important this attention is at the end of the season.

J. C. N.

THE KENTUCKY COFFEE TREE.

This North American tree is known to scientists under the name of Gymnocladus canadensis, and it has been an occupant of our gardens since 1748, although it is still rare, and well-developed examples are seldom seen. Perhaps the finest specimen in this country is growing in the gardens of H.R.H. the Duchess of Albany at Claremont. This tree is referred to in the "Trees of Great Britain and Ireland," and when Mr. Elwes measured it in 1907 it was sixty feet high, with a trunk six feet seven inches in girth. Three years later it was seen by the writer, when it appeared to be in excellent health. Another large tree is recorded in the above-mentioned work as growing at Barton, in Suffolk. In 1904 that tree was fifty-seven feet high, with a girth of five feet two inches. An example fifty feet or so high might also have been seen a year or two ago in the grounds at Chiswick House.

The species is widely distributed, as it is found from Canada to the Southern United States, where it occurs as a tree varying from thirty to sixty feet in height, or larger when growing under the most satisfactory conditions. The pinnate leaves are very large and ornamental, especially on vigorous young trees, but on old specimens they are rarely more than from one to one and a-half feet long. On young trees they sometimes exceed three feet in length, and are nearly two feet wide. A peculiar bark feature is noticeable in winter, for the younger bark is whitish. The flowers are white, and borne after the manner of those of the common robinia, but they are only produced by trees which have arrived at a moderate age.

The species thrives in ordinary garden soil, and may be increased by root cuttings. In North America the seeds have sometimes been roasted and used as a substitute for coffee, hence the common name. A second species, G. chinensis, occurs in China, but it appears to be too tender for general cultivation in the British Isles. Its seeds are said to be rich in soapy matter, and to be used as a substitute for soap in some parts of its native country.

D.

GOLDEN GARDENS.

Daffodils supply gold first, aided by the more orange crocuses, and the narcissi and jonquils that are their brethren; then gilded carpets are spread of the lemon, and the deeper Alyssum saxatile, one of the most useful furnishing perennials we possess, and deliciously honey-scented. Nodding, long-spurred columbines, amid dwarf tulips, or the primrose or saffron hyacinths, give grace to beds or borders, or may be used to similarly soften the stubby effect of the matchless wallflowers.

Glades of gold are so specially beautiful, charming the vision as do shafts of sunshine among forest trees, that it is strange how seldom cuttings are made through shrubberies, and planted with the daffodil, and golden violas for succession. Another display, on a higher level, can consist of a waving undergrowth of Spanish irises, followed by golden rods. In a sunny, hot space the noble Alströmeria aurea can be used, in a shady one the yellow day lily; poor ground will suffice fairly for yellow snapdragons, and may be dotted all over by pendulous, trembling Iceland poppies that always show at their best where breezes can freely toss them. Both these perennials, once planted, will increase and multiply till the ground becomes a field of self-sown representatives.

Why is not gold more relied on to make cheerful front gardens? Possessed of a certain warmth and richness of hue, without being garish as scarlet, or crude as carmine, it tones equally well with red, white, or grey walls, can be had in perfection from March's beginning to November's end, and with its glory the eye is never satiated. While exceedingly gorgeous beneath southern sunshine, it will suffice to gladden the shadiest tract of ground. One may almost imagine that Providence designed the daffodil, calceolaria, yellow pansy, and golden rod, mimulus and day lily, as consolations for land in shadow. Primroses provide a distinct sunbeam effect when sufficiently congregated in woodlands or gardens, and there are few lovelier sights in earliest summer than a north border full of the canary-yellow Welsh poppy that propagates itself as weeds do, in paths, or turf, or beds, chinks of the rockery, or slopes of bank-sides.

"Gold is ye coloure of God's smile," says an ancient poet. Certainly a garden in which it lacked representation at all would have a singularly lifeless appearance. To appreciate it at its full value it should be allowed to reign to the exclusion of all other hues for at least one season. By mingling mauve and white, blues, maroon, scarlet and salmon, or pale pink with it in after years new effects are secured. These introductions can take the sites vacated by biennials that have died out, and the bedding plants that were gold the former summer.

The herbaceous border will prove remarkably showy, without those long gaps that are noticed when mixed colours are used, for gold flowers have a noteworthy longevity. Before the sunflowers, heleniums, rudbeckias, heliopsises, and chrysanthemums in variety come in there should be a wealth of Aconitums pyrenaicum and aureum, Allium Moly, the classic asphodels. Barbarea vulgaris fl. pl., Centaureas montana sulphurea and macrocephala, Chelidonium major fl. pl., coreopsises, doronicums, gaillardias, lemon hollyhocks. Hieracium villosum, hypericums, lupins of several heights, various montbretias, evening primroses, carnations, Ranunculuses aeris fl. pl. and speciosus plenus, trolliuses, Scabiosas cephalaria and ochroleuca, pansies, and mulleins. Of the merits of golden dahlias, of all sections, there is no need to speak. In addition to the yellow roses of the walls, arches, and pergolas, there may be jasmines, honeysuckles, and golden ivies, aided by annual nasturtiums, including the canary creeper.

Beds of golden roses will be aided in beauty by being carpet-sown with some quite dwarf yellow annual, or the permanent yellow violetta, while lemon Iceland poppies are so light-rooting that they can safely be allowed among the bushes. The rosery may have hedges of golden privet. Bedding plants in profusion will give to the garden the luxurious, semi-tropical appearance that is so highly valued in a country such as ours, against which is often levelled the reproach of lack of colour. Yellow marguerites, cannas, gladioli, and begonias are especially beautiful.

The question whether crimson and bronze foliage of trees, shrubs, perennials, or bedding plants shall be utilised to afford striking contrast with the yellow shades, is a matter for individual taste. The deep glossy green of evergreens is an efficient relief to the flowers, or to the silver or grey-green foliage that so many of them possess. Masses of snow-white are, probably, the best to arrange when it is desired to break the golden level. It has been said that the more yellow blossoms the more the garden is visited by birds, bees, and butterflies. However that may be, sunshine will seem to have come to dwell more lovingly in this pleasaunce than in any other. M. H.

BRONZE AND TRICOLOR-LEAVED PELARGONIUMS.

To such of us as can remember these pelargoniums when in the height of their popularity, their almost total disappearance is difficult to account for. They were for a time very popular, and some of our nurserymen must have found them exceedingly remunerative; for it must be borne in mind that prices in the later sixties and early seventies were different to what they are to-day. Then it was no uncommon thing for a new variety to be sent out at a guinea each, and at that price there was a considerable demand for them. In the height of their popularity they were extensively used for bedding, and many of them were grown as specimen plants. Now all this has changed, but still I should not be surprised to see these pelargoniums obtaining favour once again. Perhaps the fact that the tricolors need very careful handling has much to do with their decline, for many old favourites are now dropped because they require extra care to be taken in their culture. The neglect of formal bedding has, of course, had much to do with the matter, but perhaps in time this may again become fashionable, and, if it happens, these pelargoniums will come once more into their own. It may be said that the present taste lies towards more natural features, but what about clipping shrubs into various shapes? W. T.

POMPON DAHLIA REGULUS.

Ruby-purple. A.M., R.H.S., and F.C.C., N.D.S., August 26. Messrs. J. Cheal and Sons, Crawley. (See page 712.)

PREPARATION OF ROSE STOCKS.

The second half of September is the ideal time for commencing this work, and by the middle of October it should be completed. This applies to all dwarf stocks, provided the wood is in a suitable condition. It is of the greatest importance to have hedge briers, for standard stocks, collected as early as possible; because in this case the larger portion have to be planted under far less favourable conditions for rooting than the smaller cuttings intended for dwarf stocks. To a great extent the collection of standard briers is checked by the game season; for undoubtedly the grubbing out of these stems must frighten and disturb a great deal of game. It is often difficult to obtain permission to collect soon enough to give the stocks a fair chance.

With these few opening remarks I will pass on to closer details in preparation of rose stocks, for however much one may wish to have all varieties upon their own roots, it cannot be done, and secure the best from but a small percentage. Besides this, the help of foster roots of a stronger nature, or that are more suited to that particular soil, must be obvious to all. If so deleterious as some few growers try to impress upon us, does not the same theory apply equally to other subjects, apples, plums, peaches, cherries, etc., all of which derive great assistance from foster roots? I am a staunch upholder of the benefits we obtain through own-root roses in the case of varieties strong enough to make a satisfactory growth, but with such a multiplicity of varieties as now exist it is unwise to dogmatise and ban any help foster roots can render in the rose garden.

The Brier, Manetti, De la Grifferaie, Polyantha, and similar stocks, can be raised from cuttings of semi-ripened wood. Let these be about nine inches long. Cut off close to the bottom eye or bud with a sharp knife. I have not yet found any secateurs that can equal the knife here, however useful they may be in many other cases. Carefully cut out all eyes up to the two, or three if closely placed, at the top of the cutting. Do not gouge these eyes out deeper than is necessary to be effective.

These cuttings may be planted in rows fifteen to eighteen inches apart, and be arranged in the rows at the rate of six to the foot. The finest soil for rooting these is a clean, sandy loam, and the addition of manure is quite unnecessary, if not sometimes harmful. Have the ground thoroughly prepared, and plant to a sufficient depth that only the tip of the cutting is visible. You will find the soil sinks quite enough naturally. Always make certain the bottom of the cutting rests firmly upon the soil. Any "hanging" or suspension of the cutting is detrimental to the formation of good roots at the bottom of the cutting, where we alone want them, and sometimes even prevents any rooting whatever. A firm settlement upon the bottom, and the soil pressed closely around them elsewhere, are two of the most essential points in rooting these useful rose stocks.

The Dog Rose as a dwarf stock is very largely raised from seedlings. A few may be purchased from nurserymen, but the bulk of these are obtained from the Continent. I would like to mention here, that so far as our own experience goes, the harder and smaller-pithed wood taken from dwarf stocks of seedling brier are infinitely better in the long run than those more promising-looking cuttings from the ripest shoulders of a standard. After the commencement, one can always secure plenty of excellent cuttings from the stocks roses were budded upon the previous summer.

A little more attention must be afforded standards or hedge briers. These are far less easy to obtain now. There are fewer thick and untrimmed hedges than formerly, and those from dense woods and copses are not so desirable as those from plants growing in the more open and exposed hedgerows. When received they are possessed of very coarse, knobby roots, with scarcely a trace of fibre. Do not purchase any with old, sear, and moss or lichen-covered stems. Nor did I ever yet succeed with a few straight stems of a white variety bearing flowers much resembling Rosa arvensis. There are so many difficulties to overcome before one can produce a really good standard (one that is sound throughout), that it is absolutely essential to start with a good stem of a suitable age. Therefore a little extra expense at the outset will be a good investment.

In the majority of cases the knobby roots already noticed are by no means removed as closely as they should be. If left on the bulk will decay. Even those which do linger on and produce a few new rootlets will not be of any real benefit, because it is so difficult to lift without breaking these off. Should these knobs continue healthy they will invariably throw up a number of most undesirable suckers, which it will be found impossible to completely eradicate. So trim the briers harder. I may say, too, that there is a greater percentage of live briers from closer-trimmed roots. Always trim over the edges of the roots with a strong and sharp knife. The collector cannot possibly avoid much bruising, and oftentimes promising roots are badly split.

A different method of planting is needed here. We plant with the bulk of the prepared stem above ground instead of below it. So uncertain and, to some extent, so unsightly are standard roses in their young stage, that they should be in beds, and transplanted to their proper places after the rose is secured.

Plant upon well-dug but fairly solid ground, and if the soil leans to the stiff side, so much the better. Allow three to four feet between the rows, and about twelve inches from brier to brier. We find it a little better when the stock is put three or four inches deeper in the soil than it was when removed from the hedgerow. Plant very firmly, and secure from any wind-waving at once. Loose soil that allows of rapid drying is inimical to the health and rooting of briers from the hedge.

One more little, but very essential, detail is the prompt planting of all prepared cuttings; any drying up of the sap must be carefully guarded against. Do not be afraid to make the soil firm, and if the frost loosens the ground during winter, press down and tread firmly.

ROSARIAN.

POLYGONUMS.

There are many polygonums, and among them there are several that are well suited for garden decoration. They vary much in growth, but most of them succeed in ordinary garden soil, and when once established are able to take care of themselves. Polygonums are not suitable for a small garden, as most of them are vigorous in growth, and require ample space, whether planted in the herbaceous border or the wild garden. The latter is probably the best place for them, as they can grow more or less at will, and at the present time they are particularly gay with innumerable blossoms.

P. sachalinense (the giant Siberian Knotweed) is the most vigorous. It frequently attains a height of ten feet, and sometimes, when growing in moist, rich soil, is even taller. Its leaves are a bright green, and fully twelve inches in length, while the greenish-white flowers are freely produced in slender drooping racemes, and give a large colony a very attractive appearance. This species is seen to advantage when planted on the banks of a lake or stream, the moist rooting medium suiting it well.

P. cuspidatum (the Japan Knotweed) is another handsome species, that often attains a height of eight feet. It is graceful in habit, bears creamy-white flowers, and may be planted as an isolated specimen on the grass, or grouped near the water's edge. In either case it should be allowed plenty of room, as it is vigorous, and, like the first-named, is not easily kept within bounds when once established. It may be worth mentioning that the best way to reduce groups of the strong-growing polygonums is to bruise off the young growths as fast as they appear in the spring. It is waste of time to dig them up, as all roots left in the ground will grow.

P. polystachyum is a native of the Himalayas, and does not grow more than five feet high, and its olive-green leaves are veined with red, and present a quite pleasing appearance throughout the summer. Its plume-like sprays of white flowers are produced in September, and continue bright and showy for several weeks. This is suitable for the herbaceous border.

P. amplexicaule has bright crimson flowers, and is quite moderate in growth, and does not attain a greater height than three feet.

P. chinense is a compact-growing species from China, with numerous white blossoms, which are produced late in the autumn. It succeeds in a moist position, and is one of the most hardy.

P. compactum does not grow more than two feet high, but produces a profusion of white flowers in late autumn.

Among the dwarf varieties P. affine, a native of the Himalayas, is one of the most desirable. Its rosy-red flowers are borne freely in dense erect spikes in September and October, and they are only about eight inches high. P. Brunonis grows about double that height, and has pale rose blossoms, produced in erect spikes during the summer. P. vaccinifolium produces its rosy flowers in profusion, and is free in growth. It thrives in moist soil, and looks its best when allowed to ramble over boulders of rock or tree stumps.

Mention must be made of P. spærostachyum, it being one of the prettiest, but not always easy to grow. An open position in the rock garden suits it, but the soil should be well drained, as it resents excessive moisture at the roots in winter, although it likes moisture in summer.

J. GARDNER.

APPLE CULTURE FOR GARDENS OF MODERATE SIZE.

It is within the memory of some of us when the standard was the only form of apple tree grown for all purposes, and this was the case even where this fruit was found growing in small gardens attached to the farmhouse, villa, or cottage. This brings to mind my boyhood days, spent in Sussex and Kent, and it is a reminder of the large standards of "August," "Ducksbill," and "Forge," that, in some instances, at that time found positions there in gardens having a limited area. Trees of this description are, of course, well known to be the best, and really the only form suitable for cultivation in ordinary orchards, they yield when the orchards are placed in favourable positions, and the trees are well managed, very heavy and profitable crops of highly coloured and otherwise excellent fruit. They are, however, altogether out of place in gardens, and especially so in those of moderate size, for, when found in them, they are invariably detrimental to their appearance, and also seriously injurious to the legitimate crops.

We have to thank enterprising nurserymen for providing, during comparatively recent years, the forms of trees known as the dwarf pyramid and the bush, which have become very popular, and are extensively cultivated for producing fruit for both market and private use. They are most suitable for small gardens, and might with advantage be much more commonly grown in them than is the case. The owners of country cottages, and of small house properties, who have not already done so, could, in many instances, profitably provide their tenants with trees to plant.

Trees of this kind will succeed well even when confined to very little space, and if a comparatively large number of varieties are desired for a given space, they may be planted at nine feet asunder, and even as closely as six feet. For reasons other than this, such as its effect on their powers of cropping, their good health, and longevity, it would be considerably better if they were allowed more space—at least twelve feet from each other. The facilities the bush and dwarf pyramid afford for attention being given to their cultural requirements, and to the attacks of insect pests and fungoid diseases, add much to their value. Then, again, the wind has comparatively little effect upon them or their fruit, and they commence to bear at an early stage, which are matters of considerable importance. These and kindred things are all benefits to be gained by growing this description of tree over that of the standard.

A mistake in training pyramid and bush trees may be easily made by allowing their branches to become crowded. This prevents their leaves, buds, and fruit receiving the full benefit from the sun, which exercises an immense influence upon the fertility of the trees, and the quality of their fruit. It should receive due consideration during the period of the formation of the trees, when it should be kept in mind that a branch possessed of developed spurs requires much more space than does a shoot. The sun's rays are not seriously obstructed on their way to the centre of a properly-managed tree, and the entire length of the branches are possessed of fruitful spurs. On the other hand, an unduly crowded tree bears but little fruit other than upon the points of its branches that are exposed to the sun.

SALVIA ULIGINOSA.

Flowers blue. A.M., R.H.S., September 9. Mr. Charles Turner, Slough. (See page 713.)

The espalier is another suitable tree for small gardens, for it takes but little space, and, in a small degree, only overshadows other crops. It is often found conveniently planted parallel to, and at a distance of a few feet from, garden walks, trained upon a trellis. When treated in this way cultural requirements of the trees can be simply supplied, and the fruit can be easily protected from birds.

The cordon, again, is a tree that can be grown in gardens that have not enough space for larger kinds of trees, and walks can be utilised by training cordons over them upon arched trellises. A greater number of varieties can be grown in a given space by employing this kind of tree than can be done by any other. The gridiron is another form of tree suitable for training upon trellises in small gardens.

Very robust-growing varieties, such as Bramley's Seedling, Warner's King, or Tyler's Kernel, are not so respondent to these modes of culture as are varieties of moderate and symmetrical habits, and that readily, and without much assistance, furnish themselves with fruit spurs. Cox's, Allington, and Sturmer Pippins, Lord Hindley, Brownlee's Russet, Braddick's and Scarlet Nonpariels, of dessert kinds, are types of this description, and Grenadier, Seaton House, Schoolmaster, Lane's Prince Albert, Annie Elizabeth, and Sandringham, of culinary varieties.

The Hendre Gardens. T. COOMBER.

DAHLIAS TO PERFECTION.—A thorough guide to the successful culture of these popular flowers is "Dahlias and their Cultivation," by J. B. Wroe, price 1s. net, by post 1s. 2d., bound in cloth 1s. 6d. by post, 1s. 8d., from W. H. and L. Collingridge, 148, Aldersgate Street, London.

NEW PLANTS AND FLOWERS.

ROSES.

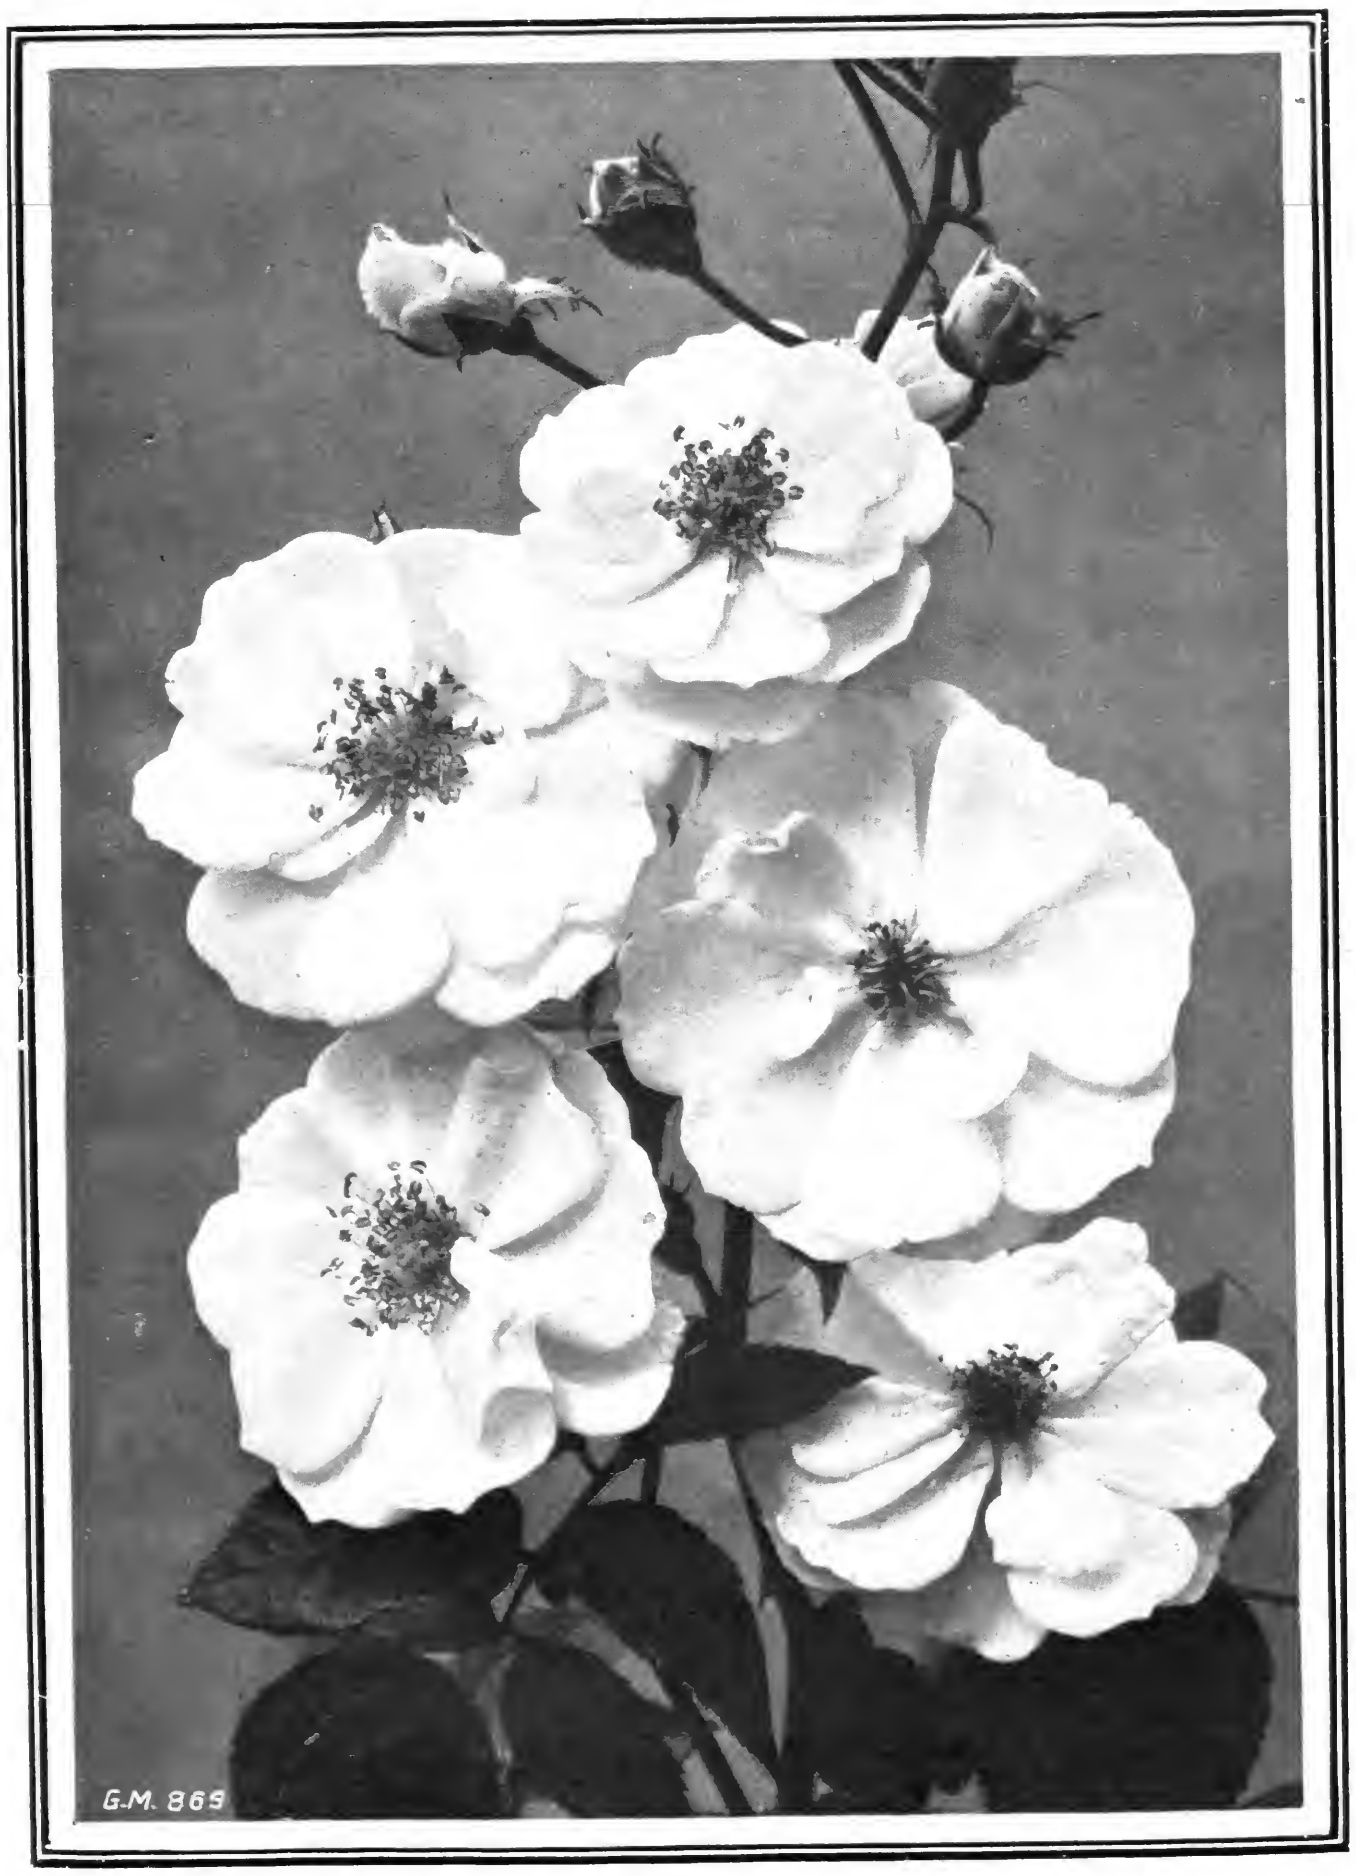
Moonlight.—A beautiful perpetual-flowering cluster rose that we have previously referred to, as it has already received the N.R.S. Silver-gilt Medal. It has dark foliage and stems, and carries its exquisitely formed semi-double flowers in large but light clusters. The colour is softest cream, with a central cluster of golden stamens. Gold Medal, N.R.S., September 11. Rev. J. H. Pemberton, Havering, Romford.

Edgar M. Burnett.—A large, broad-petalled, fragrant rose, which has deep pink colouring on the outside of the petals, and soft blush-pink on the inner surface. Gold medal, N.R.S., September 11. Messrs. Samuel McGredy and Son, Portadown.

Red Letter Day.—A showy hybrid tea rose with flowers that are not quite single, usually having several petals in a second row. The colour is rich crimson-red. Gold Medal, N.R.S., September 11. Messrs. Alex. Dickson and Sons, Newtownards.

Edward Bohane.—A large hybrid tea rose, full and broad petalled. The colour is rich rose-red with a cherry-red or almost scarlet suffusion. Apparently a strong grower. Gold Medal, N.R.S., September 11. Messrs. Alex. Dickson and Sons, Newtownards.

Muriel Dickson.—A large and brilliant hybrid Austrian briar rose with rich reddish-rose colouring, that is almost scarlet in the bud state, and has a golden glow at the base of many of its wide petals. The flowers are of good size, and not very double. Gold Medal, N.R.S., September 11. Messrs. Hugh Dickson, Lim., Royal Nurseries, Belfast.



ROSE MOONLIGHT.

Cluster rose, colour soft cream. Gold Medal, N.R.S., September 11. Rev. J. H. Pemberton, Havering, Romford.

DAHLIAS.

Dorothy Hawes.—A remarkably fine cactus variety; the blooms large, of superb form, with finely curved florets, the colour bright rose. F.C.C., and Gold Medal for the best seedling cactus variety belonging to the exhibition section, N.D.S., September 9. Messrs. J. Stredwick and Son, St. Leonards-on-Sea.

Pierrot.—A pleasing cactus variety of good form, the florets yellow, tipped with white. F.C.C., N.D.S., September 9. Messrs. J. Stredwick and Son.

E. F. Hawes.—A garden cactus variety of great promise; the blooms are of large size, bold, and borne on stiff, erect stalks eighteen inches in length, the colour light pink. F.C.C., N.D.S., September 9. Messrs. J. Stredwick and Son.

John Green.—A distinct and attractively-coloured pæony-flowered variety; the blooms are of the largest size and open out flat, the florets of great breadth, and richly coloured scarlet and bright yellow. F.C.C., N.D.S., September 9. Messrs. J. Stredwick and Son.

Rosa.—A distinct pompon of superb form and a rich purplish-rose hue, equally valuable for the garden and exhibition. F.C.C., N.D.S., September 9. Messrs. Keynes, Williams, and Co., Salisbury.

Regulus.—A beautiful variety with finely-formed blooms of a bright ruby-purple hue. A.M., R.H.S., and F.C.C., N.D.S., August 26. Messrs. J. Cheal and Son, Crawley.

Inchmarnock.—A very bright salmon-scarlet collarette dahlia, with a collar of highly developed yellow florets. A most effective variety, and of good form. A.M., R.H.S., September 9. Messrs. Dobbie and Co., Edinburgh.

ODONTIODA SEYMOURÆ ORCHIDHURST VAR.

This is a very bright and shapely orchid, derived from O. Charlesworthi and O. Bradshawiæ. The colouring is richest orange-scarlet with yellow crest. A.M., R.H.S., September 9. Messrs. Armstrong and Brown, Tunbridge Wells.

LÆLIO-CATTLEYA GEORGE WOODHAMS.

A very fine, free-flowering hybrid, obtained by crossing Cattleya Hardyana with Lælia purpurata. It has been exhibited before, but on this occasion was brought up for judgment. The flowers are of large size, and generally borne in threes, though a spike of four blooms is by no means uncommon. The sepals and petals are rich mauve, while the broad lip is deep crimson-purple, with a little yellow at the base. A.M., R.H.S., September 9. Messrs. Armstrong and Brown, Tunbridge Wells.

ASTER FELTHAM BLUE.

A sturdy variety of the Novi-Belgi group of Michaelmas daisies. The flowers are freely produced in light and elegant clusters, so that each head is seen distinctly. The colour is lavender-blue, and this is enhanced by the dark wiry stems. A.M., R.H.S., September 9. Messrs. Thos. S. Ware, Lim., Feltham.

SALVIA ULIGINOSA.

A hardy herbaceous perennial with fragrant, mint-like leafage, and spicate heads of bright blue flowers. The spikes are dense and terminal, and the calyces persist after the corolla has fallen. The chief attraction is the half-inch wide blue lip. The species grows strongly, often reaching a height of 5ft.; its fragrance and bright colouring will render it attractive for wild gardening, and for positions near water. It is a native of Brazil. A.M., R.H.S., September 9. Mr. Chas. Turner, Slough.

STANHOPEA CONVOLUTA.

A handsome species, first discovered in the province of Antioquia, Colombia, whence it was introduced by Mr. F. Claes, in whose establishment at Etterbeck, Brussels, it first flowered. The plant which supplied the material from which the illustration in the "Botanical Magazine" was prepared was presented by Messrs. Charlesworth and Co. to Kew in 1911, with whom it bloomed in October of that

year, and in the corresponding month of 1912. The flowers are rather large, the sepals and petals soft yellow, the reverse greenish-yellow freely spotted with red, the lip yellow, white, and orange. Bot. Mag., t. 8507.

CENTAUREA CRASSIFOLIA.

A distinct and attractive species, endemic in Malta, where it is met with mainly in the central portion of the island. The introduction of this composite to British collections is due to Professor Rev. G. Henslow, V.M.H., who sent a plant to the Cambridge Botanic Garden as far back as 1894. At Cambridge it is grown in the succulent house, and thrives under much the came conditions as the sempervivums. The flower heads are about an inch in diameter, and the colour is purple-rose. Bot. Mag., t. 8508.

CYTISUS SUPRANUBIUS.

This species of broom is a native of the Canaries, and is described by Dr. Schenck as the most characteristic plant of the Alpine region of Teneriffe, where it is abundant between 6,000 and 9,000 feet above the sea-level. In Teneriffe it forms a compact, globular shrub five feet in diameter, and in height, and under favourable conditions produces its cream-white flowers in great profusion. The species is not hardy in the open in most parts of the United Kingdom, but in the Royal Botanic Garden, Glasnevin it thrives against a sunny wall and blooms freely. Bot. Mag., t. 8509.

GREVILLEA PINNATIFIDA.

This handsome species is a native of rocky localities in the neighbourhood of the Swan River, and, with reference to its merits, it is said that "among the many species of the genus in cultivation in Europe it is one of the most ornamental, not only on account of the beauty of its flowers, but also because of the charm of its foliage." The flowers are produced in elegant terminal racemes, are light red, and the leaves are elegant, and, as indicated by its specific name, distinctly pinnatifid. Bot. Mag., t. 8510.

SOLENOSTEMON GODEFROYÆ.

A pleasing species, first discovered by Mr. and Mrs. Monteiro in 1873 about fifteen miles from Ambriz in Angola, but was not distinguished from S. ocymoides. Thirty years later it was found in the Congo State by Mr. Godefroy Lebeuf, who introduced it to cultivation and placed it in the genus Coleus. The leaves are dark green with prominent veins, and the pale blue flowers are produced in erect spikes, the plants blooming freely throughout the winter months. Bot. Mag., t. 8511.

THINNING GOOSEBERRY BUSHES.

When all the fruits have been gathered and the nets removed, it is a good plan to give gooseberries a thorough clean up, at the same time removing all suckers. If the bushes are too dense to admit air and light thin them out rather freely; the young fruiting shoots will then have a much better chance to grow firm and sturdy. I know only too well that in most gardens there is very important and pressing work to be done just now, consequently the bushes are very apt to be overlooked, but if time and labour will admit of its being done give the bushes every attention. All ours will receive at least two good soakings of liquid manure to assist the formation of strong healthy buds by the end of the season. It is surprising how beneficial is such assistance after the fruit has been gathered. H. Markham.

ROSE EDWARD BOHANE.

H.T.; colour rose-red. Gold Medal, N.R.S., September 11. Messrs. Alex. Dickson and Sons, Newtownards. (See page 712.)

PASSIFLORA CÆRULEA.

The common blue-flowered Passion Flower (Passiflora cærulea) is hardier than is by many supposed to be the case, and in many parts of the suburbs of London, as well as over a wide district in the southern counties, it forms, by reason of its pretty blossoms, a showy summer feature. What is more, when favourably situated, the egg-shaped fruits are freely produced, and when ripe their bright yellow colour always arrests attention. Beside the ordinary form there is a white-flowered variety—Constance Elliott—which first appeared in a Devonshire garden about thirty years ago. It is equally hardy with the type, and in the colour of its blossoms affords a pleasing variety thereto. Even where they cannot be depended upon out of doors these passion flowers are of considerable value for the cool greenhouse, as they are not harmed by even a few degrees of frost. It is of rapid growth, and will soon cover a considerable space. Seeds germinate readily, and from these young plants can be easily raised, while cuttings can be rooted without difficulty. This last mode of increase is preferable, as plants obtained in this way flower more freely when young than seedlings do. The white variety cannot be depended to come true from seed.

S. W.

SALVIA VIRGATA NEMOROSA.

Although including some of the most distinct and useful of the herbaceous plants that can be successfully cultivated in the open in British gardens, the hardy salvias have for a long series of years received but little attention even from those who have an objection to the use of tender plants in the embellishment of the flower garden. Why this should be so it is difficult to understand, but the statement is indisputable that one might visit a considerable number of gardens wherein hardy border flowers are extensively and well grown without seeing a single representative of the genus.

It might, indeed, be said that although included in some of the trade catalogues of hardy perennials, Salvia virgata is practically unknown beyond the boundaries of botanic gardens. The illustration given herewith of its variety nemorosa will afford a good idea of the manner of plant it is. From this it will be readily seen that the plant forms a compact bush, and produces innumerable flowers, borne on slender, erect spikes. Something more than black and white is necessary to portray its beauty and effectiveness, but when it is stated that the flower stems are furnished throughout the greater part of their length with large calyces of a rich claret colour and innumerable small bright blue flowers, there will be no great difficulty in understanding its distinguishing characteristics. The variety S. virgata nemorosa has a more woody growth than the specific form, and the flowers are perhaps of a more brilliant shade of blue, reminding one, by their colour, of the spring gentian. It attains a height of about two feet, is superior to the type, and worthy of a position in the most select collection of hardy flowers. Both S. virgata and its variety can be successfully cultivated in any ordinary garden soil, and can be readily increased by division in the spring.

Both in the shape and the arrangement of the flowers S. virgata nemorosa bears a rather close resemblance to the remarkably handsome hardy Salvia uliginosa, for which Mr. C. Turner obtained an Award of Merit at the Royal Horticultural Society's meeting on the 8th inst. The latter is, however, much taller, attaining a height of about five feet, is larger in all its parts, and very distinct. The portion of the flower spike illustrated in this issue will, nevertheless, be useful for the purpose of showing the distinctive inflorescens of the hardy salvias with highly-developed and richly-coloured calyces, and bright blue flowers of moderate size. S. virgata nemorosa produces its flowers during August, and the Mexican S. uliginosa a little a month later.

SALVIA VIRGATA NEMOROSA.

Finely-grown specimens of this handsome blue-flowered salvia at Kew.

Begonia Bertini.—This is a very useful begonia for bedding out during the summer months. It does not belong to that dwarf race now so popular, but partakes more of the character of the original B. boliviensis—that is to say, the flowers are long and drooping. The flowers of B. Bertini, which are freely borne on stout, erect stems, are bright-red in colour. It belongs to the same section as B. Worthiana.—W.

Bedding Begonias.—Of late years a double-flowered race of dwarf-growing begonias has become very popular for bedding purposes, some of the best-known being Count Zeppelin, Lafayette, Major Hope, and Washington. Some other varieties were well shown by Messrs. Blackmore and Langdon, Twerton Hill Nursery, Bath, at the meeting of the Royal Horticultural Society on August 26. Among them were Argus, whose ranunculus-like flowers, produced well above the foliage, are of an intense rich scarlet colour; Marquis of Stafford, of a rich deep crimson; and President Sargent, pale yellow. Other desirable qualities of this section are: Calliope, pink; Gladiateur, crimson; Holyhock, pink; Lord Langton, scarlet; and Mrs. Langtry, white. The begonias of this class maintain a succession of flowers over a lengthened period.—J.

STANDARD GUIDES TO THE GARDEN

Published at "GARDENERS' MAGAZINE" Office, 148 & 149, Aldersgate Street, London, E.C.

"THE IDEAL BOOK FOR A PRESENT."

The FLOWER GARDEN.

By T. W. SANDERS, F.L.S.

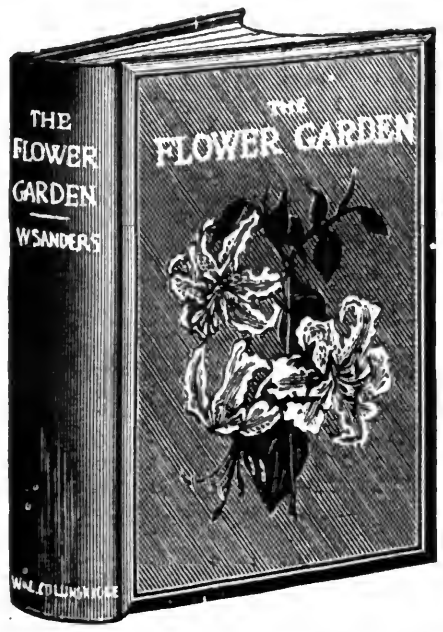
Bound in cloth, bevelled edges, 480 pages.

7/6 net;

By post, 8/-

SIXTY-FOUR PLATES
Beautiful Garden Scenes, Plants and Flowers, and
FORTY EXPLANATORY DIAGRAMS.

A comprehensive work on the Formation, Planting, and Management of the Flower Garden, and the Cultivation of Flowers, Plants, &c., adapted for Outdoor Culture.



"Of great assistance to those who have greenhouses or intend to build one."—THE FIELD.

THE AMATEUR'S GREENHOUSE.

By T. W. SANDERS, F.L.S.

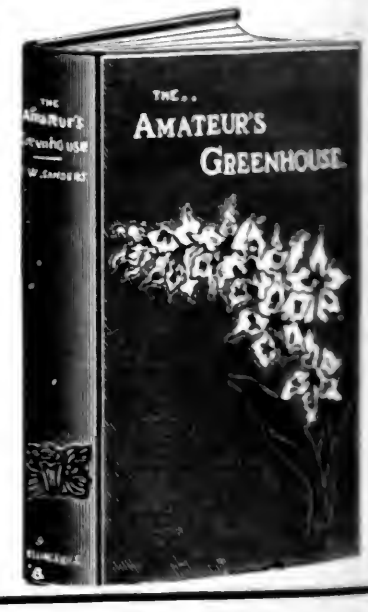
Bound in cloth, 416 pages.
154 illustrations.

5/- net;

By post, 5/6

SEVENTEEN PHOTO PLATES and — TWO COLOURED PLATES. —

A Complete Guide to the Construction, Heating and Management of the Greenhouse, and the Cultivation of Greenhouse Plants.



"A most excellent five-shillingsworth."—THE LADIES' FIELD.

VEGETABLES and their CULTIVATION.

By T. W. SANDERS, F.L.S.

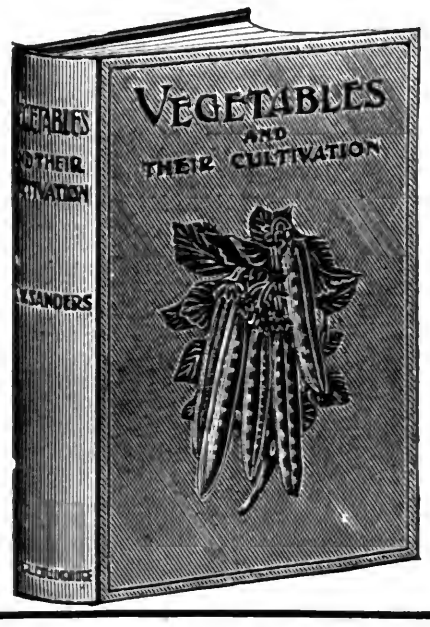
Bound in cloth, 464 pages, 140 illustrations.

5/- net;

By post, 5/6

EIGHT PHOTO PLATES and FIVE COLOURED PLATES.

An up-to-date Practical Guide to the Formation and Management of the Kitchen Garden: Soils, Manures, and Culture of Vegetables for Home Use.



FOURTEENTH EDITION—REVISED—ENLARGED—IMPROVED

ENCYCLOPÆDIA OF GARDENING.

By T. W. SANDERS, F.L.S.

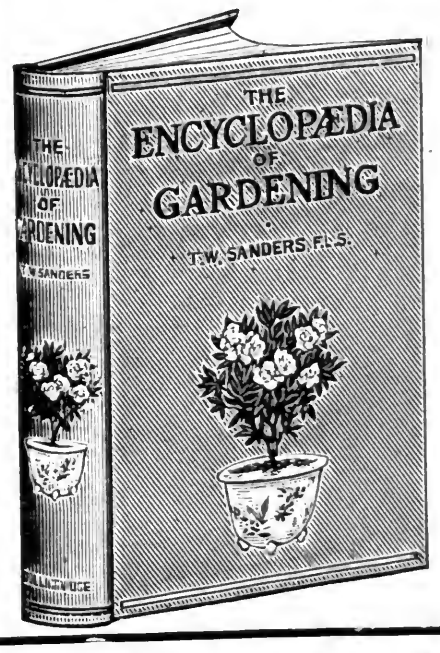
Bound in cloth, 482 pages.

3/6 net;

By post, 3/10

A complete Dictionary, giving at a glance the Cultivation and Description of every Flower, Fruit, Vegetable, Plant, Tree, or Shrub; Popular and Technical Names, Time of Planting, Colour of Flowers; Name of every Species, Suitable Soil, &c., &c.

A Popular Garden Guide.



ROCK GARDENS AND ALPINE PLANTS.

By E. H. JENKINS, F.R.H.S.

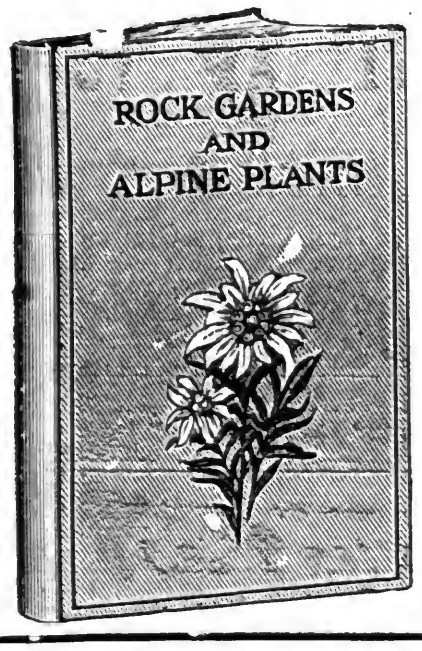
Bound in Cloth.

FORTY-TWO FULL-PAGE PLATES AND OTHER ILLUSTRATIONS.

2/6 net;

By post, 2/10

A complete Guide to the Formation and Management of Rockeries in Small and Large Gardens: also the Cultivation and Propagation of easily-grown Alpine Plants in the Open-air and in the Cold Greenhouse, Frame, and in Window Boxes.



"May be heartily commended to the notice of owners of small greenhouses as a reliable and sound guide."—WEEKLY IRISH TIMES.

ORCHIDS FOR AMATEURS.

By C. A. HARRISON, F.R.H.S.

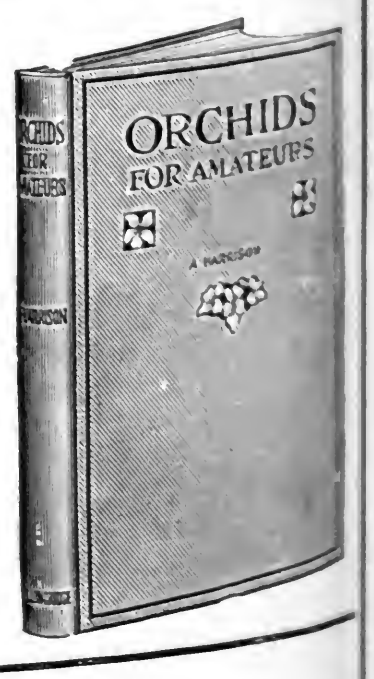
Bound in Cloth.

TWENTY FULL-PAGE PLATES.

2/6 net;

By post, 2/10

A practical Guide to the Cultivation of easily grown Cool and Warm House kinds, adapted for Small Mixed Greenhouses.



To the Publishers, 148 and 149, Aldersgate Street, London.

THE DEVELOPMENT OF PLANT EMBRYOLOGY.

Miss Ethel Sargant, who presided over the botanical section of the British Association, devoted her presidential address to the developments of the study of the embryology of plants during the past forty-three years. After referring to the great loss that had been sustained by all who were interested in the study of natural history by the death of Lord Avebury, Miss Sargant said there was one more event of the past year that should be mentioned. A great innovation had been made by the Council of the British Association in choosing a woman as president of the botanical section, and she would not refrain from thanking them in the name of her sex because she happened to be the woman chosen. And, though she felt very keenly the honour they had done her as a botanist, yet that feeling was less prominent than gratitude for the generosity shown to all women in that choice. Speaking in their name, she might venture to say that the highest form of generosity was that which dared to do an act of justice in the face of custom and prejudice, as had been done by the Council in this case.

In proceeding to deal with the subject matter of her address, Miss Sargant urged that embryology should include every stage in the development of the plant from the first division of the fertilised egg-cell to maturity. They were forced to study the embryo because its characters were often of systematic importance. The structure of the embryo could not be completely grasped by reference to its past only. The observer must expect adaptive characters of three kinds: first, those imposed upon the embryo in the past by its development within the embryo-sac while it was still parasitic on the parent plant; secondly, certain adaptations to the process of germination itself; and, finally, characters which would be useful after germination. Before the utility of the characters included in this third class could be fully understood, the development of the seedling must be followed for some time. In short, the structure of the embryo was dependent on its future, as well as on its past; and a division of the subject which excluded that future was purely artificial.

In reviewing recent research in plant embryology, Miss Sargant dealt at some length with the evidence afforded by the embryos of plants of the remote ancestors from which they may be derived, and compared the results of this research with the evidence found in fossil remains.

To compare, she said, the structure of organisms with each other is, of course, the recognised method of comparative anatomy, of systematic botany, and, in fact, of all branches of morphology. The great difficulty in all such work is to distinguish between adaptive characters of comparatively recent origin and the characters inherited from remote ancestors. The history of systematic botany is very instructive in this respect. Systematists discovered by degrees, and by means of repeated failures, that characters could not be picked out as important for purposes of classification on à priori grounds. No character is of uniform importance throughout vascular plants, for example. On the contrary, it may be of great value in the classification of one group and worthless in another, though closely allied. Generations of botanists have laboured to build up the natural system in its present form, and it is constructed from the ruins of abandoned systems. We all agree now that the guiding principle in all morphology is that our classification should represent relationships founded on descent only. But the natural system was complete in its main features before that principle was understood. It represented the feeling for real affinity developed in botanists by the study of plant form, independently of any theory as to the cause of such affinity.

This, of course, is the commonplace of botanical history, but we do not always realise that all morphological work is done under similar conditions. The only valid appeal from criticism is to the future: a new method is approved by its results. Therefore, to embark on a new branch of morphology is a real adventure. The morphologist risks much time and much labour. He knows that the evidence which he proposes to gather painfully, to test critically, to present logically, may, after all, prove of little consequence, and he has to depend on his own instinct to lead him in the right course. In his degree he resembles Columbus, to whom a few sea-borne seeds and nuts meant a new continent. Hence the difficulty of criticising recent work. When once a conclusion of some importance has been formulated it may be tested by evidence drawn from other branches of research. Until that time criticism from outside is of little value. Those who are working at the subject must, of course, form their own opinion on its possibilities, for each has to decide for himself whether he shall continue on those lines, or endeavour to find others that he can follow with the probability of success.

The subject of seedling anatomy is no longer very new. It is too late now to debate on the à priori probability of ancestral characters surviving in the young seedling. No one doubts that a vascular stump sometimes persists after the organ it originally supplied has disappeared. Therefore there is no glaring improbability in the suggestion that the vascular skeleton of the young seedling may afford a clue to the structure of a remote ancestor. But this is only saying in other words that botanists are justified in giving the subject a fair trial. That trial is now proceeding. Some general conclusions have been formulated already, but they have not yet stood the test of time. In all probability the final judgment on this subject will be given by a future generation of botanists on evidence not as yet before us. In the meantime we shall all form our own opinion as to the prospects of the method. Speaking for herself, Miss Sargant thought that it has already thrown much light on embryological problems, and it is likely to throw more

---

INFLUENCE OF GARDENING ON CHILDREN.

On page 613, issue August 16, you have a very interesting note on the above subject. For more than twenty years I have taken a great interest in school gardening, and, indeed, was one of the first to take an active part in the teaching of children on gardening subjects. It was my privilege to give a few brief lectures to children in a country school, and also to teach them how to grow crops in the garden of the schoolmaster who had a large one, and gave up a portion to the children. He also taught them during a given time once or twice each week, and, at the annual inspection, H.M. Inspector examined the children, and passed the school a "first" in gardening for the Government grant. I do not remember other schools at that time having received such a grant. Since then it has been a great pleasure to me to teach school children, in various centres, a little about gardening, and I can testify to the keen interest they take in the subject, and the refining influence it has on them in after years. I may add that the parents of these children were among the most successful exhibitors at the different local shows. The school referred to is that at Fawley, near Southampton, the schoolmaster being Mr. F. Cove.

GEO. GARNER.

Hydrangeas.—These may now be propagated by means of strong, well-matured cuttings. Place them singly in small pots in a sandy compost, and plunge the pots in a mild hotbed. When rooted gradually harden them off, eventually exposing them to full sunshine and plenty of air, so that they may become thoroughly ripened. By the end of autumn they must be induced to rest by gradually withholding water.—E. HARRISS.

SCHOOL GARDENING IN SCOTLAND.

There has just been brought to a close at Aberdeen very successful school gardening vacation classes for school teachers, under the auspices of the Aberdeen Centre for the Training of Teachers. They were taught at the experimental garden of Aberdeen University by Mr. Robert M. Clark, B.Sc., botanical department of the University, and Mr. Lewis Gavin, Drumwhindle Public School, Aberdeenshire. The splendid work accomplished by the last-named gentleman in connection with school gardening has made his name known throughout the length and breadth of Scotland. The classes were very largely attended by teachers from all parts of the northern half of Scotland, and were very fittingly brought to a close by a visit paid to Mr. Gavin's school garden at Drumwhindle, some twenty miles from Aberdeen, where a practical demonstration was given of how the work of laying out and conducting a school garden should be gone about. Accompanying the party were Mr. Frank Young, LL.D., Glasgow; H.M. Chief Inspector of Schools for Scotland, Mr. J. T. Ewen; H.M. Inspector of Schools for the Northern Division of Scotland, and Dr. Smith, director of studies at the Aberdeen Provincial Centre for the Training of Teachers. A description of a visit paid to Drumwhindle School Garden was given in THE GARDENERS' MAGAZINE of July 8, 1911.

After extending a hearty welcome to his visitors, Mr. Gavin at once proceeded to show the principal features of his now famous school garden. Commencing with the potato area, Mr. Gavin explained that of the fourteen varieties grown, it had been found that the order of merit so far had been as follows: First, Devanha. Three of equal merit which followed were Grampian, Fortyfold, and Reading Russet. Then came British Queen, Harbinger, Faithlie, and Balgownie. This season Snowdrop and Ashleaf made a poor show.

The experiments with regard to vegetables also evoked considerable interest, while the company derived much pleasure from an inspection of the flower beds and borders, Mr. Gavin emphasising that the æsthetic as well as the utilitarian aspect of school gardening ought to be considered, while in rural districts the farmers must be induced to co-operate with the school authorities on the subject. That could best be done by going in for a course of experiments in regard to farm plants.

The inspection proved a delightful experience, and the company then adjourned to the main schoolroom, where tea was served. After tea, Dr. Smith, Aberdeen, proposed a vote of thanks to Mr. Gavin for his kindness in arranging the inspection of his school garden. Dr. Smith then called upon Dr. Young, Chief Inspector, to address the gathering.

Dr. Young, after expressing his pleasure at being present, congratulated the members of the classes on school gardening upon the able direction given them by Mr. Clark and Mr. Gavin. They could not have had better guides. He had the utmost confidence when they were appointed that the work before them would be effectively performed, and especially had he been greatly impressed with the ability and skill Mr. Gavin had shown in carrying through the operations. It was good for them to be there, but instead of building tabernacles he hoped they would start to make gardens. Dr. Young also congratulated Mr. Clark and Mr. Gavin on having had such an industrious and interested class, as had been evident from the notebooks of the students he had examined, and these afforded good ground for them carrying their operations into the districts from which they came. The Education Department, continued Dr. Young, desired to encourage that practical work in their supplementary classes, and he thought they would aim at giving as liberal a grant as for experimental science work. They must, however, realise that the Department had the Treasury to consider.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

MASDEVALLIAS. — The large-flowering masdevallias, such as M. coccinea, M. ignea, M. Veitchi, and the thick-leaved section, to which M. gargantea and M. leontoglossa belong, may now be repotted if necessary. When plants have grown into large specimens it is undesirable to disturb them more frequently than is absolutely necessary, but all should be thoroughly examined at this season of the year. Decaying material and dead leaf bracts should be carefully removed, and where the potting compost has become sour on the surface, fresh material should be given. Plants that have become hollow in the centre from loss of leaves should be carefully turned out of their pots and divided, and after the potting compost has been removed the divided portions be placed in the centre of suitable-sized, well-drained pots or pans, arranging them to the best advantage. Good fibrous peat and chopped sphagnum, with plenty of finely broken crocks and sand intermixed, form the best compost for masdevallias. This should be pressed moderately firm about the base of the plants, and slightly mounded to the centre. By keeping the leaf base above the surface of the compost there is less danger from damping and decay during the winter months. If a house has a north aspect, little or no shading will be required after this note appears, but with brighter positions all freshly-potted plants must be shaded with discretion until the roots have established themselves in the new compost.

SEEDLING CYPRIPEDIUMS.—There are no plants that make greater progress than seedling cypripediums during the late summer and autumn months, and after a prolonged period of excessively dry atmosphere outside, the small seedlings seem to be making unusual progress since the moister and cooler conditions have set in. As the small plants produce roots when the first and second leaf is being made, it is desirable to transfer as many as possible into single or store pots as soon as the work in the cooler houses permits. The stronger plants should be removed to larger pots as their needs demand. It is not advisable to delay potting, as there is nothing retards young plants of cypripediums more than the want of rooting space. As larger pots are needed a coarser potting compost should be used. For all but the tessellated-leaved section some fibrous, turfy loam should be added, with ample sand to keep the compost porous. Close observation must be kept for thrips, and it is a good plan to spray with some safe insecticide about once a week at this season of the year.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

FUCHSIAS.—Few plants are more useful for the greenhouse or conservatory than the fuchsia. Whether grown as specimens, or trained under the roof of the greenhouse, or other low structure, they invariably attract much attention. Nowhere is the fuchsia seen to greater advantage than in the latter position, and when once established in a restricted border the plants will last for years with little trouble beyond pruning and cleaning annually. To obtain really fine examples for flowering next year, cuttings should be inserted in the autumn and grown on in a steady temperature through the winter, eventually planting them out in the spring. The cuttings which are most suitable are those which are free from flower buds, and have been fully exposed to light and air; and if they can be taken off with a heel of harder wood attached to them they will root more readily. Insert the cuttings near the sides of 5-inch pots, and plunge the pots in a hotbed of moderate warmth. Put them into small 60-size pots when sufficiently well rooted, and grow them near the glass in a temperature of 55 or 60 degrees. This treatment is also suitable for specimens.

MALMAISON CARNATIONS.—The layers which were rooted early in August, and were potted and placed closely together in cold frames, will now be freely established in their pots. They must be placed near to the glass in a light, airy structure, as the damp conditions of cold frames are favourable to the development of the rust. They must not, however, by any means be coddled, therefore keep the ventilators wide open at all times till there is danger of very severe frost. Supply water to all Malmaisons with great care, and keep the atmosphere as dry as possible. Do not shade them after this date, and do everything possible to encourage strong, sturdy growth.

PERPETUAL - FLOWERING CARNATIONS.—The most forward of these which are coming into flower may be given plenty of stimulants. Give them abundance of fresh air as long as the outside conditions will allow, and do not unduly crowd them, as this encourages attacks of rust, besides causing a general weakening of the entire stock. If strong, healthy grass is available a batch of cuttings may now be inserted.

BULBS.—As soon as the main batch of bulbs has arrived from the nurseryman lose no time in potting them up. The latest batches may be plunged in ashes in the open. Lilium Harrisi and Lilium longiflorum may be potted singly in 32-pots and placed closely together in cold frames. Cover the bulbs with fibre until growth has commenced; they may then be brought indoors and placed on a shelf near the glass.—E. HARRISS, Lockinge Park Gardens.

HARDY FRUITS.

BUSH APPLES.—The crops of fruit on most bush trees is heavy, and this, coupled with the long spell of drought, will make it necessary to give the trees every attention at the roots to assist the formation of strong, plump buds for the production of next season's crop. Our trees growing on a rather shallow soil have, during the past two months, received thorough soakings of liquid manure, and will be given at least two more. These remarks apply also to other kinds of fruit trees in need of help, especially cordon pears with roots near the surface. The practice of feeding early in autumn cannot, I think, be too strongly recommended where the soil is light and the crops heavy.

MORELLO CHERRIES.—Most of the fruits will by this date have been gathered; the crops at Wrotham have been very satisfactory, and the trees will now have all useless wood cut out. The roots will then be examined, and, if needed, a good top-dressing of suitable compost will be applied early. Morello cherries should be very thinly trained, so that light and air may reach all parts of the shoots and assist the wood to harden by the end of the season. Should the trees be infested with scale or other insect pests give them a thorough washing with a nicotine solution.

FRUIT GATHERING.—This highly important matter will need daily attention, and should have precedence of other work. Apples are best stored in a cool, sweet, well-ventilated room, and should be gathered when dry and not bruised. Cox's Orange Pippin and other very choice dessert varieties should be gathered as they come to maturity. All very late-keeping kinds should be allowed to remain on the trees until the seeds have changed to a dark brown colour; otherwise the fruits will not keep well. With us Bramley's Seedling, Lane's Prince Albert, Old Winter Nonsuch, and Gooseberry apple are the best for late supplies. The latter is an excellent old variety, but not so extensively called for as it was many years ago. Carefully look over the pear trees, and gather all the fruits as soon as they are fit; remove them with care, and place them carefully on the shelves where they are to remain until ripe. A few may be hastened along if required by placing the fruits in boxes and standing the boxes in a warm place.

GRAFTS.—If not already done, some of the largest shoots may be shortened a little, and others made secure to light canes fastened to the stems of the trees or branches on which they have been worked, to prevent injury by winds.—H. MARKHAM, Wrotham Park Gardens.

THE KITCHEN GARDEN.

CARDOONS.—During dry weather these plants will require a plentiful supply of moisture at the roots, clear water and liquid manure being alternately afforded, and the soil is thoroughly moistened to a good depth. Tying up the plants to blanch should be done on a dry day, and the operation should not be long delayed. Bind each plant with hay-bands, after drawing the leaves straight, and follow this by earthing up the stalks with fine soil.

FRENCH BEANS.—A good sowing may now be made in 9in. pots of Ne Plus Ultra, Masterpiece, or Osborne's Forcing, using a loamy soil and spent mushroom bed manure thoroughly well mixed. Sow half a dozen seeds in a pot. A cool pit or frame will suit the sowing for the present; if forced too hard in the early stage, growth will be thin and weak. Plants in bearing should have the usable pods removed as soon as they are fit to gather.

CELERY.—Where the rainfall has been slight, and not sufficient to reach the roots, good applications of water will be necessary, taking care not to wash the soil into the hearts of the plants. Celery intended for use late in October should be moulded up for the last time if the crop is sufficiently advanced, otherwise the operation should be deferred, as the close contact of the soil somewhat arrests growth. Continue to mould up the crops when the stalks are thoroughly dry and the heart-leaves are a few inches out of the soil.

TOMATOES.—Gather the fruits as soon as they are slightly coloured, and lay them thinly in a vinery to ripen. All surplus growth should be removed from the plants, and the fruits fully exposed to the sun. Tomatoes prepared for fruiting in the autumn should be placed under glass. For the next few weeks the air of the structure should be kept in a genial, buoyant state day and night. The amount of water afforded should be enough and no more; if the plants are carrying a good crop of fruits a moderate amount of feeding will be beneficial.

BEET.—Some roots of the early varieties may be taken up and stored, but the main lot need not be disturbed for a fortnight or three weeks. Where early frosts are to be expected the crops should be lifted in good time and pitted. By pitting the crop it is possible to have perfectly sound roots up to the end of next May. Preferably about a barrowload should go to each pit. When larger pits are formed, in taking out roots for immediate use, the air is admitted, and growth is induced. The roots should be laid in a circle, tops outwards, and built up conewise; cover with a good layer of bracken or clean straw litter, and on this add three or four inches of soil, made smooth and firm.

GENERAL WORK.—Take advantage of wet days to rope onions, sort over the early potatoes, tie mats, etc. Clear the ground of all kinds of rubbish, burning this on the smother fire. Early frosts may soon be expected, and precautions should be taken to afford protection as much as possible to such subjects as may require it.—W. MESSENGER, Woolverstone Park Gardens.

THE NATIONAL CHRYSANTHEMUM SOCIETY'S
EXHIBITION OF EARLY-FLOWERING

CHRYSANTHEMUMS

Will be held at the

CRYSTAL PALACE,

On OCTOBER 1st and 2nd, 1913.

Write for Schedule (post free) to the Secretary,
Mr. RICHARD A. WITTY,
72, Savernake Road, Gospel Oak, S.W.

ADMISSION TO PALACE (including Show), 1s.

YORK

CHRYSANTHEMUM SHOW,

NOVEMBER 12th and 13th.

Prizes over £150. Schedules from
CHAS. W. CLACK,
Secretary.
12, New Street, York.

NORTH OF ENGLAND HORTICULTURAL SOCIETY.

The AUTUMN SHOW will be held in the CORN EXCHANGE, LEEDS, on the 9th and 10th October, 1913.

Applications for space, etc., to be made to Mr. A. J. ALLSOP, Parks Superintendent, Roundhay, Leeds.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

National Rose Society.

The autumn exhibition of this society, held in the Royal Horticultural Hall, Westminster, on Thursday and Friday, September 11 and 12, was not such a good one as that held in 1912. There were plenty of flowers on view, but the quality was not so high as previously, owing largely to the dry weather experienced in so many districts. The flowers did not last well on this occasion, and those who visited the exhibition on the second day only were very disappointed with the flowers. The depredations of mildew were evident on all sides, and very few were the stands or vases where the foliage showed no signs of this troublesome fungoid pest.

The attendance was large on the first day, but, of course, the N.R.S. and R.H.S. ticket-holders formed the bulk of the crowd. On September 11, 84 persons paid 2s. 6d. at the doors; 79 paid 1s., and 162 paid 3d., the total receipts being £16 9s. 6d., as against £23 5s. on the first day in 1912. The experiment of charging 3d. for admission in the evening cannot be considered a success; indeed, not a few members expressed the view that a threepenny admission lowered the dignity of the society.

NEW ROSES.

Gold medals were awarded to the following roses: Edgar M. Burnett, from Messrs. S. McGredy and Son, Portadown; Red Letter Day and Edward Bohane, from Messrs. Alex. Dickson and Sons, Newtownards; Moonlight, from the Rev. J. H. Pemberton, Havering; and Muriel Dickson, from Messrs. Hugh Dickson, Lim., Belfast. For descriptions see "New Plants."

SILVER MEDAL ROSES.

The best blooms or silver medal roses in the trade section were all shown by Messrs. Alex. Dickson and Sons, Newtownards, which seems to us to be a record. The flowers were: H.P., Ben Cant; H.T., George Dickson; T., Alexander Hill Gray.

In the amateur section the best H.P. was Horace Vernet, shown by Rev. R. F. Cobbold, Stony Stratford; best H.T., Joseph Hill, shown by Mr. J. Turner, Gourock; best T., Henri Berger, from Mr. Burgess, Tonbridge.

NURSERYMEN.

No fewer than seven competitors came forward in the class for three dozen blooms, distinct, and the premier award fell to Messrs. Hugh Dickson, Lim., Belfast, for capital blooms of Dr. O'Donel Brown, Brilliant, Maman Cochet, Mdme. Eugene Verdier, Frau Karl Druschki, Marquis de Gany, Mdme. Joseph Combet, Ulrich Brunner, etc. Messrs. Alex. Dickson and Sons, Newtownards, secured second prize, and Messrs. J. Cocker and Sons, Aberdeen, were third.

Messrs. Alex. Dickson and Sons, Newtownards, led for seven baskets of roses, distinct varieties, with Dean Hole, George Dickson, Duchess of Wellington, Mrs. George Shawyer, Gladys Harkness, Mdme. Melanie Soupert, and Mrs. J. Laing. Mr. John Mattock, Headington, Oxford, second; and Messrs. S. McGredy and Sons, Portadown, led for a basket of twelve blooms of an exhibition rose with British Queen, followed by Messrs. Alex. Dickson and Sons with George Dickson.

The best collection of eighteen vases of perpetual-flowering, decorative roses was won by Mr. John Mattock, Headington, with a bright collection that included Peggy, Mrs. H. Stevens, Irish Glory, Irish Elegance, Lady Hillingdon, La Tosca, Dorothy Page Roberts, etc.; Mr. George Longley, Chapel Lane Nurseries, Rainham, second; and Mr. J. Pigg, Royston, Herts, third. For a set of nine varieties under similar conditions, Mr. Frank Woollard, Lewes Road, Brighton, came first, and his best vases were of Lyon, Ecarlate, La Tosca, Irish Elegance, and Jacques Vincent; Mr. Elisha Hicks, Hurst, Berks, second; and Mr. Chaplin, Joynings Nursery, Waltham Cross, third.

Another good class was the one for nine baskets of perpetual-flowering, decorative roses, and here Messrs. Hugh Dickson, Lim., Belfast, secured the first prize with fine baskets of blooms of Mrs. Thos. Paul, Miss Mona Hunting, C. K. Douglas, Gustave Regis, Irish Elegance, Golden Gem, Simplicity, H. E. Richardson, and Mrs. Jas. Williamson; Mr. J. Mattock a good second, with flowers that lasted well into the second day; and Mr. W. Chaplin, Waltham Cross, third. Five baskets of roses, distinct, baskets not to exceed fourteen inches in diameter, made a good class, as there were four entries. Messrs. Chaplin Brothers, Waltham Cross, led the way with Mdme. Abel Chatenay, Irish Elegance, General McArthur, Gustave Grunerwald, and Lady Ashtown. Messrs. Bide and Son, Farnham, came second, with flowers that lasted well during the second day; their Rayon d'Or, Irish Elegance, and Mrs. A. R. Goodwin were especially good; Mr. George Prince, Longworth, third.

Mr. J. Mattock was a good first for two dozen varieties of decorative roses, in vases of seven blooms each, and he showed Irish Elegance, Mrs. H. Stevens, Gottfried Keller, Lady Waterlow, A. R. Goodwin, and Rayon d'Or in fine form; Mr. J. Pigg, Royston, second; and Messrs. Paul and Son, Cheshunt, third. The best dozen varieties, similarly shown, were from Mr. E. Hicks, who staged his flowers admirably; Messrs. W. and J. Brown, Peterborough, second.

The gold medal for a group of roses, not exceeding 150 square feet, was won by Messrs. Paul and Son, Cheshunt, with a pleasing exhibit of pot plants of Sunburst, Mdme. J. Dupuy, etc., and round baskets of Frau Karl Druschki, Lady Hillingdon, Mdme. A. Chatenay, Mrs. S. G. Crawford, Hugh Dickson, etc. Palms and bamboos formed a pleasing background, and ferns were used as edging. Messrs. Hobbies, Lim., won second prize, and the chief attraction of their exhibit consisted of arches of the yellow Lady Hillingdon rose, set over vases and stands of numerous useful varieties.

The premier award and gold medal for a display of cut roses arranged on a table space of 18ft. by 6ft., rose foliage only allowed, was won by Messrs. W. and J. Brown, Peterborough, with an effective and bold exhibit of arches of bloom, backed by vases and stands of varying height set over small vases and baskets. Mdme. Constant Soupert, Mdme. Pol Varin-Bernier, General McArthur, Juliet, Duchess of Wellington, and Mrs. G. Sharman Crawford were a few outstanding varieties. The silver-gilt medal fell to Messrs. Dobbie and Co., Edinburgh, with bold stands of good blooms of Frau Karl Druschki, Mrs. Theodore Roosevelt, Mrs. J. Laing, Duchess of Wellington, Lyon, and Caroline Testout. For a similar display, but with only 60 sq. ft. of space allowed, Messrs. B. R. Cant and Sons, Colchester, won first prize with a very bright exhibit, in which Irish Elegance, Rayon d'Or, Lady Hillingdon, and Lyon were boldly staged. Messrs. G. Jackman and Son, Woking, second.

Mr. J. Mattock was the only competitor in the class for three dozen distinct varieties of roses, in vases, not fewer than three stems of each, and he put up a glorious exhibit of fine bunches of Mrs. J. Laing, A. R. Goodwin, Medea, Anna Olivier, Niphetos, Lady Waterlow, Marie Van Houtte, J. B. Clarke, Mdme. Abel Chatenay, Mdme. Hoste, etc. For eighteen varieties, similarly staged, Mr. H. Drew, Longworth, was given first prize, and was the only exhibitor.

AMATEURS.

Mr. E. C. Eversfield, Denne Park, Horsham, led for eighteen exhibition blooms with a fair set of popular varieties; Rev. J. H. Pemberton, Havering, second. Mr. J. B. Turner, Ardmay, Gourock, N.B., brought down a dozen fine blooms, and was the first of four competitors in the amateurs' section; Mr. G. Speight, Market Harborough, second, and Mr. G. Slaughter, Steyning, third.

Mr. E. B. Lehmann, Ifield Lodge, Crawley, scored for nine blooms distinct, followed by Mr. R. de V. Pryor, Preston, Hitchin, and Mr. H. Balfour, Headington Hill, Oxford. For nine tea and noisette roses, Mr. F. Slaughter was a good first, and he had a good Mrs. Foley Hobbs and Mrs. Edward Mawley; Mr. Speight second.

Mr. J. Walter Smith, Sparrow Herne Hall, Bushey, scored for seven vases of roses with a good set, in which Irish Beauty was prominent; Mr. E. C. Eversfield, Denne Park, Horsham, second. The Rev. J. H. Pemberton, Havering, scored for three baskets of roses with Danaë, Frau Karl Druschki, and Caroline Testout, and was also first for a dozen vases of as many varieties, not fewer than three stems of each; here he had his new varieties Danaë and Moonlight in fine condition, as well as The Lyon, Rayon d'Or, etc.; Mr. H. R. Darlington, Park House, Potter's Bar, second, and Mr. E. S. Gordon Clark, Fetcham Lodge, Leatherhead, third.

Mr. H. A. Gerhold, Penarth, led for six vases of decorative roses, and the Rev. J. H. Pemberton scored for a dozen bunches, again showing Moonlight, Danaë, Trier, Adrian Reverchon, etc. The chief prize-winners in other amateur classes were Captain R. Kilbie Stuart, East Woodhay, Newbury; Mr. M. S. David, Tonbridge; Rev. R. J. Cobbold, Beachampton Rectory, Stony Stratford; Mr. W. H. Dove, Newport, Isle of Wight; Mr. Burgess, Tonbridge; and Mr. P. T. Davis, Burgess Hill.

LADIES' SECTION.

In the class for a dinner-table decoration of roses there were thirteen competitors, and the first prize was awarded to Mrs. L. Courtney Page for a beautiful table of the pale yellow Melody; Irish Elegance, arranged in silver vases and bowls by Mrs. J. Walter Smith, Bushey Heath, secured second prize, and third prize fell to Mrs. George W. Cook, Radstock, Whetstone, for a handsome design in the variety Old Gold. Mrs. Colston Hall used the latter variety, and gained a fourth prize.

In the dinner table class, open only to lady trade members, Mrs. Arthur Bide, Highlands, Farnham, took first prize with a free use of the pretty variety Sunburst.

Mrs. Colston Hall, Virginia Lodge, Warminster, had the best bowl of roses, and

showed Irish Elegance and Killarney in pleasing combination; Miss Jessie Langton, Hendon, second, and Miss E. M. Davis, Burgess Hill, third; six entries. Mrs. Colston Hall was also first for a basket of roses, and here confined her attention to Irish Elegance; Mrs. H. A. Gerhold, Penarth, second, and Mrs. Chas. Williamson third; six entries.

For a low bowl of roses Mrs. Edgar Burnett, Holly Lodge, Southgate, scored with Lady Mary Ward; Mrs. L. Courtney Page, Enfield, second, and Mrs. Colston Hall, third.

Edinburgh Autumn Show.

The following portion of our report of the autumn exhibition held by the Royal Caledonian Horticultural Society at Edinburgh on the 10th and 11th inst., was unavoidably held over from our last issue:

BOUQUETS.

Baskets and vases of flowers were beautifully shown, much artistic skill being exercised in the arrangement, and tasteful blending of the colours of the flowers. A white hand bouquet, shown by Mr. John Hood, gardener to F. G. Bishop, Esq., Dalmore, Helensburgh, received first prize. White lapagerias, roses, Francoa, and double gypsophila were skilfully used to good effect. Mr. Wm. Holmes, Rockend, Helensburgh, was given second prize. Mr. A. Holmes, Bellevue Bank, Helensburgh, being third. Mr. John Hood again scored for a coloured bouquet, using statice with white flowers and broad lavender-tinted ribbon. Mr. W. Holmes and Mr. A. Holmes secured second and third positions. Mr. D. Kidd, gardener to Lord Elphinstone, Carberry Tower, received first prize for a beautiful basket of berries and foliage, and a similar award for a vase of foliage of hardy shrubs. Mr. J. McFadyen was placed second in the latter class, third prize going to Mr. Jas. Bethel. In another basket class Mr. Kidd was once more the winner, Mr. McFadyen following. Mr. Kidd was also successful with a decorated epergne, using one of the popular silvered rustic receptacles, which he filled with flesh-pink carnations, francoa, and trails of bronze selaginella. Mr. J. Bethel used gloriosas and anthuriums with croton leaves, making a bright and rich-looking arrangement, for which he received second prize. In the open classes for bouquets, Messrs. John Hood, A. Holmes, and Wm. Holmes pretty equally divided honours, and they showed some very good bouquets, using appropriate flowers and foliage with great taste.

NON-COMPETITIVE (SCOTTISH EXHIBITORS).

Messrs. Dobbie and Co., Edinburgh, made an immense display of sweet peas and collarette dahlias. The staging covered 400 superficial feet, and not a bad bunch of flowers was used, either among the sweet peas or the dahlias. It is impossible to name the best varieties staged, but we may mention, as quite new sweet peas, Ruby Palmer, a very brilliant red; Mrs. McIlwrick, a variety possessing two distinct shades of mauve, and King White. Messrs. Dobbie also put up a group of early-flowering chrysanthemums, occupying about 250 square feet. A big ground space was occupied by Messrs. Thyne and Son, Dundee, who made a feature of sweet peas in triangular groups on all sides of a central mound of larkspurs, lupins, clarkias, and other good annuals. Antirrhinums were also used to advantage in this exhibit.

Pot fruit trees were the main feature of Messrs. Storrie and Storrie's exhibit from Glencarse, Perthshire. Highly-coloured fruits of well-known apples hung thickly on shapely young trees, and the pears were equally good in size and quantity.

Messrs. John Forbes, Lim., Hawick, made a bold and striking display of pentstemons in the centre of a forty-foot stage, the side portions being well furnished with phloxes and a miscellaneous selection of hardy border flowers. We have so frequently quoted names of varieties shown by these well-known herbaceous phlox specialists, that we feel it is necessary to do no more than say the cream of the Hawick collections was represented in this capital exhibit.

Messrs. Cunningham, Fraser, and Co., Comely Bank Nurseries, Edinburgh, showed a collection of herbaceous and sub-shrubby plants, among which were some most interesting rarities. Mutisia decurrens showed its elegant, clear, orange gerbera-like flowers in a manner but rarely seen, and Sutherlandia frutescens, with its bladder-like seed vessels, was also well shown. Berberidopsis corallina and quite a number of very useful and uncommon subjects made up a grand exhibit. Messrs. J. Cocker and Sons, Aberdeen, showed herbaceous flowers of merit. Tritomas, crinums, phloxes, and montbretias played their part, and Artemisia lactiflora, Potentilla Gibson's Scarlet, and Sidalcea Rosy Gem were good things noted. Messrs. Cocker occupied another stand with an exhibit of roses, embracing many of our choicest hybrid teas and decorative garden roses. Messrs. Chas. Irvine and Sons, Jedburgh, put up phloxes and pentstemons, both of which they showed well. Messrs. Jas. Grieve and Sons, Redbraes Nursery, Edinburgh, staged early-flowering chrysanthemums, dahlias, and a few pentstemons. Phloxes were the outstaanding feature on the stand put up by Mr. D. McOmish, Crieff. The big, bold bunches of Sheriff Ivory, Iris, and other distinct coloured sorts were very effectively staged.

Mr. John Downie, Shandwick Place, Edinburgh, displayed tuberous begonias in good variety, together with collections of phloxes, pentstemons, and early chrysanthemums. At the back of the stand were tall bunches of eryngiums, aconitums, etc., and small ferns and grasses were judiciously used among the begonias. Messrs. R. B. Laird and Sons, Lim., Frederick Street, Edinburgh, exhibited a group of conifers, which included splendidly grown specimens of Retinospora obtusa aurea, Abies nigra, Pinus cembra, and Cupressus Lawsoniana argentea picta, besides good cedars and thujas, etc. The group was brightened by the introduction of herbaceous flowers and roses. Mr. D. W. Thomson, George Street, Edinburgh, showed a batch of the brilliant Pentstemon Mrs. F. Fulford, which we have before mentioned as one of the most striking of pentstemons. The firm's East Lothian stocks were also well shown in shades of purple, crimson, pink, and white. Messrs. Gemmell Bros., Oxenford Nurseries, Kilwinning, Ayrshire, exhibited pentstemons. Although shown as unnamed seedlings, the quality of the flowers, length of spike, and clearness of colour was of a high standard. Mr. John Johnstone, Law, by Carluke, staged pansies and violas, the flowers being extremely fine. Messrs. Matthew Campbell and Son, High Blantyre, made a brave show of dahlias and border carnations, the latter being quite good for so late a date, whilst the cactus dahlias were a grand lot of flowers.

NON-COMPETITIVE (ENGLISH EXHIBITORS).

More than ordinary complimentary adjectives would be necessary to do justice to the very creditable exhibit of choice stove and greenhouse plants brought from Chelsea by Messrs. Jas. Veitch and Sons, Lim. Of the arrangement we need make no further remark than that every plant seemed to show itself to best advantage, and at the same time assist its neighbours by throwing their distinctive characteristics into relief; but mention may well be made of a few outstanding plants that played an important part in the group. Nepenthes in several choice varieties were mounted on tall columns overreaching the general level, and in the background were tall crotons, Alocasia Watsoniana, and other species of this handsome genus, together with big plants of davallias, dracænas, etc.; while in the groundwork were marantas, dieffenbachias, ferns, and crotons, with groups of orchids, cannas, and nerines.

Quite characteristic of the firm's best efforts was the splendid display of vegetables and flowers arranged by Messrs. Sutton and Sons, Reading. It goes without saying that everything was put up in a manner that could not be improved upon, and although everything shown was extremely good, there were examples of peas, onions, and melons that stood conspicuously in the foreground, and immediately claimed special notice. The Superlative, Universal, and Triumph melons were good, well-ripened fruits, and the floral decorations were charming. An extensive array of dahlias and fine sweet peas shown by Messrs. Geo. Fairbairn and Sons, English Street, Carlisle, were very attractive; tall vases were filled with clean flowers of good varieties, and the colours of the flowers were well set off by the use of trails of smilax. Messrs. G. Gibson and Co., Leeming Bar, Bedale, staged great masses of border perennials, among which hybrid verbascums, Lilium tigrinum, gladioli, and helianthuses were prominent. Phloxes, pyrethrums, montbretias, and tritomas were other subjects used in the exhibit.

A great pyramid of charming border flowers put up by Messrs. Harkness and Sons, Bedale, contained many things worthy of note. Hybrid verbascums were conspicuous and very fine, gladioli were rich in colour, and a great sheaf of rosy lupins, which crowned the group, showed up to advantage above mauve daisies and golden helianthuses. Orchids from Messrs. F. Sander and Son, St. Albans, included such things as Catasetum macrocarpum, Brassia Lewisi, Bulbophyllum grandiflorum, and a number of Lælio-cattleyas and choice cypripediums. Messrs. Pipers, Bayswater, London, were extensive exhibitors of choice herbaceous flowers, and of pæony-flowered dahlias. The double tiger lily was well shown, and Rudbeckia fulgida, Romneya Coulteri, and a salmon-coloured seedling phlox were other good bunches.

A group of begonias brought up from Feltham, Middlesex, by Messrs. T. S. Ware, Lim., contained some splendidly-flowered plants of excellent varieties. Considering the lateness of the season, the vigour of the plants and size of the flowers was splendid, and the sturdy, erect habit of the plants was commendable. Mr. A. F. Dutton, Iver, Bucks, showed a good group of perpetual carnations, Mrs. A. F. Dutton, a large quantity of the useful rosy-salmon flower being tastefully arranged in artistic baskets. Messrs. Young and Co., Hatherley, Cheltenham, were also exhibitors of carnations, their varieties including some of the best in commerce, arranged, as ever, in a very pleasing manner. They also had on view a remarkably vigorous plant of a perpetual carnation, which has been growing and flowering out of doors in a Scottish garden.

Messrs. Jones, of Kilkenny, exhibited gladioli, which ranged in colour from white to almost black, with all gradations of rose and salmon, scarlet, crimson, and mauve. Mr. H. N. Ellison, West Bromwich, showed greenhouse ferns in great variety. Nephrolepis Duffi was distinct and charming, and another good fern shown was Nephrolepis amabilis, with strap-shaped leaves, beautifully crested from end to end. Big chrysanthemums were staged by Messrs. W. Artindale and Son, Sheffield, who also had dahlias, phloxes, and other hardy flowers. Phlox Comtesse de Jarnac had almost entirely cream-coloured foliage with pale mauve-tinted flowers. Messrs. Wm. Cutbush and Sons, Highgate Nurseries, London, showed a bold group of herbaceous and bulbous flowers, and also some good perpetual-flowering carnations. Liliums and gladioli were prominently displayed among heleniums, montbretias, early asters, and gaillardias.

Messrs. W. Wells and Sons, Lim., Merstham, Surrey, had good perpetual carnations as well as chrysanthemums and phloxes, all being good, well-grown flowers of up-to-date varieties.

Mr. Amos Perry, Enfield, Middlesex, showed a great mass of his improved achillea named Perry's White, and also Helenium autumnale rubrum, and another excellent variety named Bronze Queen, with Spiræa filipendula grandiflora, a much-improved form of a useful plant.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE, September 9.

Present: E. A. Bowles, Esq., M.A., in the chair; Messrs. R. H. Curtis, J. Fraser, W. Hales, Arthur W. Hill, Jas. O'Brien, J. W. Odell, Gurney Wilson, and W. C. Worsdell.

ADAGLOSSUM x JUNO. — Mr. O'Brien showed a new bigeneric hybrid, and a Certificate of Appreciation to the exhibitor of Adaglossum x Juno (Ada aurantiaca x Odontoglossum Edwardi) was unanimously recommended.

ABNORMAL GLOXINIA.—Mr. O'Brien showed, for Mrs. Myles Kennedy, an abnormal form of gloxinia (referred to Mr. Odell for report).

ALBINO WILD FLOWERS.—Mr. Dipnall, of Hadleigh, Suffolk, sent an albino form of Carduus nutans, with some notes on colour variations, and added that he had recently discovered white forms of Vicia lathyroides, Prunella vulgaris, Geranium lucidum, and G. dissectum. These had occurred within a quite restricted area, and this suggested the possibility that soil had something to do with the variation. He had also found a bronzy-purple Papaver Rhœas, pale pink Centaurea nigra, and clear pink Myosotis palustris.

ASTERS FAILING.—Lady Howick sent asters with decayed shoots. The committee recommended the splitting up of the old plants as the base of stems sent were hard and had lost vitality.

JAPANESE GRASSHOPPERS.—Mr. Odell showed for Mr. Goodacre, of Moulton Paddocks, a number of the Japanese grasshoppers (Diestrammena marmorata), and observed that the insects had established themselves in the large conservatory at Moulton, and had also invaded the mansion. The problem now was to exterminate them. They are large handsome insects in the larvæ stage. When fully matured they will be very formidable-looking creatures.

NARCISSUS BULBS DISEASED.—The Rev. J. Jacob sent two parcels of narcissi. These were referred to Kew for investigation.

LIME TREE MITE.—A parcel containing the lime tree mite was sent to Mr. Michael for identification.

KEFERSTEINIA LAMINATA. — Kefersteinia is a section of zygopetalum, in the form of the flowers nearest to promenæa, and in habit of growth (which is leafy, the pseudo-bulbs being rudimentary) to Warscewiczella. The species are chiefly Colombian, and there are some ten known species of which K. graminea is the best known. K. laminata has white flowers with rose markings on the fringed lip. From Messrs. Armstrong and Brown, Tunbridge Wells.

Scottish Horticultural Association.

The monthly meeting of this association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on the 2nd inst. Mr. J. Phillips, the senior vice-president, was in the chair, and there was an attendance of ninety members.

Mr. George Stuart, Lecturer in Horticulture at the Edinburgh and East of Scotland College of Agriculture, gave a lecture and demonstration on "Fruit and Vegetable Bottling." The preserving of fresh fruit and vegetables by means of sterilisation was, Mr. Stuart said, comparatively little known in Scotland, and our supply of these came chiefly from the Continent and America. If the small grower would realise how simple the process was, he could add to his income by adopting it, and could obtain at a very small cost the necessary appliances, consisting of bottles, steriliser (which might be a pot or other suitable vessel large enough to hold sufficient water to cover the bottles up to the necks), and an ordinary floating dairy thermometer. The most serviceable bottle was the quart size, which held about 2lbs. of fruit. The essential thing in bottling was that when the bottles were filled they were perfectly air-tight. By raising the temperature of the water in the steriliser gradually, and keeping it at 150 degrees (Fahr.) for a sufficient time, all the organisms capable of producing fermentation were destroyed, the air was drawn out, and when the bottles cooled the lids, which rested on rubber rings, were quite air-tight, and the contents would keep in perfect condition for any length of time. On the motion of Mr. Fife, Mr. Stuart received a very cordial vote of thanks.

The exhibits were: New collarette dahlias, exhibited by Messrs. Dobbie and Co., Edinburgh (varieties, Eddystone, Tuscar, and Dungeness, awarded First-class Certificates); new seedling geranium, Little Nan, exhibited by Mr. Wm. Cunningham, Bella Vista, Duddingston; spikes of Gilia coronopifolia, exhibited by Mr. Alex. Porter, Davidsons Mains (awarded a Cultural Certificate); decorative rose, Leone Lamesche, exhibited by Mr. J. Alexander, Niddrie, Midlothian; spikes of Brugmansia Wrighti and Eucomis punctata, exhibited by Mr. Alex. Johnstone, Hay Lodge, Edinburgh; autumn-sown Trebons onions, exhibited by Mr. C. Comfort, Broomfeld, Davidsons Mains (awarded a Cultural Certificate).

At the meeting on October 7, Mr. D. Armstrong, Kirknewton House Gardens, Midlothian, will read a paper on Salvia splendens.

United Horticultural Benefit and Provident Society.

The monthly meeting of this society was held at the Royal Horticultural Hall on Monvice-chairman, Mr. J. Harrison Dick, who the chair. Four new members were elected. The sick pay for the month on the ordinary side was £63 13s. 4d., and on the State side £39 0s. 8d., and the maternity claims £12. Two members were allowed to withdraw double the amount of interest—£4 and £3 17s. 4d. respectively—while one member over 70 years of age withdrew from his deposit account £8 11s. 6d. The sum of £14 19s. 11d. standing to the credit of a deceased member was passed for payment. One member was granted 5s. per week for life from the Distress Fund. The committee are taking action to bring the Amendments of the National Insurance Act into force, so that members over the age of 50 and 60 years will receive 10s. per week benefit instead of 7s. and 6s. respectively, and members over 65 years will receive medical benefits after January 12, 1914.

The committee regret the loss of their vice-chairman, Mr. J. Harrison Dick, who is held in high esteem by all the members of the committee, as he is shortly leaving this country. On behalf of the committee the Secretary (Mr. A. C. Hill) presented him with an illuminated address, accompanied by a gold fountain pen. The committee one and all wishing Mr. Dick God speed and good luck. Mr. Harrison Dick, replying, said he was surprised to receive such a valuable gift, and should cherish the same as long as he lived, and hand it down to the future generations.

French Chrysanthemum Shows, 1913.

The following are the dates and places where chrysanthemum shows will be held in France during the coming season: L'Association Française des Amateurs et Jardiniers Chrysanthémistes, Paris, October 14 to 19; National Horticultural Society of France, Paris, October 24 to November 2; Horticultural Society of the Vosges, Epinal, November 8 to 15; Horticultural Society of the Ain, Bourg, November 8 and 9; Horticultural Society of the Gironde, Bordeaux, November 5 to 10; French N.C.S. Comité régional, Fontainebleau, October 25 to 27; Horticultural Society of the Basses-Pyrénées, Pau, November 6 to 10; Horticultural Society of Havre, November 8 to 10. At Caen a show will be held early in November, date not yet fixed.

General Bulb Growers' Society of Haarlem.

The several Floral Committees of this society have made the following awards at their recent meetings: First-class Certificate.—To Gladioli Liebesfeurer, dark scarlet; Pink Perfection, dark rosa with white stripe, feathered dark rose, shaded lilac; Electra, salmon-red, with white spot; Prince of Wales, apricot, the lower petal yellow, feathered red, raised from seeds; Badenia, clear lilac-blue, and dark blue spot; and Montbretia Star of the East, flowers very large, stellate, colour orange-yellow, in the centre sulphur-yellow, the flower buds dark orange-red, raised in England.

Award of Merit.—To Gladioli Lemoinei Incontestable, pure white, in the centre spotted orange and carmine, originated from Guerasey; Queen of the Pinks, rose-tinted, shaded lilac, with small carmine spot, raised from seeds; Fermillon Brillant, scarlet red, with small yellow stripe; Mrs. Frank Pendleton, jun., clear salmon rose, with purple spot; Adeline, clear lilac-violet, the lower petal dark violet, feathered white; Mahony, auburn, feathered dark brown; Rosa Lindt, lilac-rose, with large white spot in the centre, striped dark purple; Goliath, wine-red and lilac; Clear Eye, carmine red, centre white, striped purple, originated in England; Sulphur Perfection, fine clear yellow, with coppery-yellow shade on the lower petal; Alice Roosevelt, rose-white; Yellow Hammer, sulphur-yellow, raised from seeds; Fritjof, clear red, shaded scarlet, and a small yellow spot; Lucifer, carmine-red, lower petals spotted dark carmine and white; Cattleya, soft lilac-rose, the lower petal spotted white; and White Giant, pure white, with a little carmine in the centre; Montbretia Frans Hals, yellow spotted brown, raised from seeds; and Lord Nelson, orange-red, shaded brown, in the centre golden-yellow, obtained in England.

Wellcome Horticultural Society.

The second show this year of the Wellcome Horticultural Society was opened on September 6, at the Wellcome Club and Institute at Dartford. The silver cup presented to the society by Mr. Henry S. Wellcome as a trophy to be awarded annually, and held for a year by the member scoring the highest aggregate of points in a season, was won by Mr. John T. Blackman, and was duly handed to him by Mr. G. E. Pearson, the general manager of Messrs. Burroughs, Wellcome and Co. Prizes were also awarded to the winners of the various classes. There were over 180 entries.

East Anglian Horticultural Club.

There was a good gathering of members at the September meeting, to hear a paper by Mr. A. J. Oakley, of Hobbies, Lim., Dereham, upon "Hardy and Half-hardy Annuals." After an explanation of the definition of the terms, Mr. Oakley gave a lengthy list of kinds, and their suitability for various positions. He also dwelt upon their usefulness in the production of colour scheme effects, and the way these plants have come to the fore in recent years for the embellishment of glasshouses during the spring months. The subject brought out a very animated discussion.

There was a good general exhibition of fruits and vegetables, and a special display of dahlias from Daniels Bros., Lim., Norwich.

Chironia ixifera. — Some good examples of this shrubby gentianwort, which was recently referred to in THE GARDENERS' MAGAZINE, were shown at the Horticultural Hall on August 26. It is a native of South Africa, and, under cultivation, forms a rather upright bushy specimen, clothed with narrow glaucous green leaves. The lilac-pink flowers are very freely borne. —W. T.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of THE GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of THE GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in THE GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

INTERNATIONAL EXHIBITION AT NEW YORK.—J. W., Liverpool: Will you please give me the name and address of the secretary of the International Flower Show to be held in New York next year?—The secretary is Mr. John Young, 54, West 28th Street, New York.

HOUSING PERPETUAL CARNATIONS.—M. E., Halstead: I have some good plants of perpetual carnations, in pots, plunged in ashes out of doors, but sheltered from rain by means of glass lights supported on a wooden frame. They have made splendid growth lately, and a friend suggests I should house them at once. My contention is that unless severe weather sets in the plants will be better out of doors than in the greenhouse. Kindly give me your opinion on this matter.—The plants should be housed without delay; indeed, we consider perpetual carnations grown out of doors during the summer should be housed directly September commences. The cool conditions of autumn induce free growth in the outdoor plants, but such growth is very susceptible to attacks from rust, and the longer the plants remain unhoused the greater is the danger in this direction. Under glass drier atmospheric conditions can be provided, and a firmer growth secured such as will withstand disease and flower well. Nor is anything gained, provided the plants have been properly stopped, by attempting to retard the period of flowering by means of open air treatment.

GRASS OF PARNASSUS.—S. R., Torrington: I am anxious to plant some Grass of Parnassus in my little bog garden, but am not certain as to the best time to plant. I have already marked some good specimens not far from my home, where they grow well in a wild marshy spot, but I do not wish to move them until the proper time arrives. Your help will be greatly appreciated.—You may move and transplant the specimens of Parnassia palustris at almost any time from now until the end of October, but if circumstances prevent planting being done by the latter date, it will be well to wait until the early spring, when signs of new growth appear.

PLANTING HARDY CYCLAMENS.—C. C. H., Keswick: The autumn-flowering hardy cyclamens have greatly interested me during the last week or so, and I am wishful to plant some corms. It seems to me that I have an ideal position on a warm, sheltered bank, thinly shaded by trees, where the soil is chiefly vegetable matter overlying chalk. Kindly advise me as to the probable suitability of such a site, and also the best time to plant.—In such a warm, well-drained position as that indicated the hardy cyclamen should prove successful. Planting must be done when the corms are at rest, that is, during June or July for the autumn-flowering kinds, and October or November for the spring-flowering kinds. There seems no good reason why you should not try both sections, unless you are absent from home during the springtime. Shallow planting is desirable, and the corms should be so placed that the top of each is level with the surface of the soil. If it is easily procurable add some rich sandy loam to the staple soil. Cyclamen africanum, C. cilicicum, C. græcum, C. neapolitanum, and C. europæum, flower variously from late summer to late autumn. C. Coum often flowers quite in the winter, and continues into spring. C. repandum or C. bederæfolium, C. libanoticum, C. ibericum, and C. Atkinsi flower in the spring. These will provide sufficient for a start, and then a few others may be added if these succeed.

FORMALDEHYDE FOR BLACK SPOT ON ROSES.—W. G. F., Wimborne: My employer has purchased a bottle of formic aldehyde solution for spraying roses suffering from Black Spot, but no directions were sent with the bottle of solution, indicating at what strength it should be used, so I should be grateful if you can inform me how this fungicide should be used.—We expect the fungicide you refer to is Formaldehyde, which has been found efficacious in the treatment of black spot on roses, at the rate of one tablespoonful to a gallon of soft water for summer spraying, and two tablespoonsful to a gallon of water for winter spraying. Formaldehyde is about a 40 per cent. solution of formic aldehyde, so, if it is the latter you have, you must gauge accordingly. A tablespoonful of commercial formaldehyde (40 per cent.) in a gallon of water is a one-eighth per cent. solution, and two table spoonsful is a one-fourth per cent. solution. It will be better to obtain commercial formaldehyde and spray the roses and surrounding ground with a solution as suggested, every week or ten days, using the stronger (two tablespoonsful) solution, after leaf fall, at mid-winter and in February.

FALLING APPLES.—H. P., Yeovil: I am in some trouble because such a large number of our apples are falling from the trees. This is not due to wind or to insect pests, as the apples are perfectly sound and the weather has been capital. Can you suggest a reason for Wellington, Lane's Prince Albert, and other late apples falling in such numbers at this early date.—We think that dry weather is the cause of premature falling of apples; we have noticed that where watering and mulching have been carried out in gardens, the crops are good and few fruits have fallen; but in the case of orchard trees, or those in gardens which have not been watered, the fruits have fallen in large numbers. Watering now will assist the trees, but is not likely to be of much service in saving the present crop of fruit.

NAMES OF PLANTS.

W. S., Croydon.—Bignonia radicans.

L. L., Brighton. — 1, Trachelium cæruleum; 2, Hibiscus syriacus.

S. R., Corbridge.—1, Eupatorium purpureum; 2, Berberis stenophylla; 3, Rudbeckia amplexicaule; 4, Othonnopsis cheirifolia.

T. P. O., Whitehaven.—1, Aster acris; 2, Achillea filipendula; 3, Sedum spectabile; 4, Hypericum Moserianum; 5, Dabœcia polifolia.

M. M. G., Stafford.—1, Artemesia annua; 2, Rudbeckia speciosa: 3, Anemone vitifolia; 4, Quercus Cerris; 5, Prunus Pissardi; 6, Senecio Clivorum.

O., Guildford.—Oncidium microchilum, a variable species, and somewhat rare in cultivation. It was discovered in 1838 by Mr. G. Ure Skinner, in Guatemala, and flowered for the first time in this country, at Manchester, in 1841. It is not a particularly attractive species, and the form you have is especially dull.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

MONDAY, September 22.—National Chrysanthemum Society; Floral Committee at Essex Hall, Strand, at 3 o'clock; Executive Committee at 7 o'clock.

TUESDAY, September 23.—Royal Horticultural Society; Committees meet at 12 o'clock; Lecture at 3 p.m. on "Autumn Border Plants" by Mr. Bernard Crisp. The Dahlia Competition and Vegetable Show will be held on this date.

WEDNESDAY, September 24.—Kendal Flower Show. Kendal Fruit and Potato Congress; two days.

THURSDAY, September 25.—Royal Horticultural Society's Exhibition of British-grown Fruits; two days.

FRIDAY, September 26.—Annual Conference of Affiliated Societies at the Royal Horticultural Hall at 3 p.m.

SATURDAY, September 27.—Longformains Horticultural Society.

METEOROLOGICAL OBSERVATIONS.

CATALOGUES RECEIVED.

DICKSONS, CHESTER.—A comprehensive list of bulbs, retarded plants, sundries, and seeds for autumn sowing.

ROBERT VEITCH AND SON, EXETER.—Special attention is given to the best daffodils and to selections of bulbs in this list. The new hybrid cineolarias are also described.

THOS. S. WARE, LIM., FELTHAM.—Two handy and well-arranged catalogues; one devoted to bulbs and various spring-flowering plants, and the other to roses, fruit trees, and flowering shrubs and hardy plants.

BEES, LIM., LIVERPOOL.—A gorgeous catalogue the covers, inside and out, carrying coloured illustrations of scillas, tulips, hyacinths, iris, and gladioli, the intervening pages are packed with information concerning bulbs.

H. CANNELL AND SONS, EYNSFORD.—The first catalogue from this old firm, since taking up its headquarters at Eynsford, is devoted to fruit trees, ornamental trees and shrubs, roses, hardy herbaceous plants, seeds for autumn sowing, and zonal pelargoniums.

JAMES CARTER AND CO., RAYNES PARK S.W.—One of the most interesting bulb catalogues we have ever seen. On the covers Clara Butt rose is depicted in colour, and inside are coloured portraits of Arum Mrs. Roosevelt, and Daffodils Emperor, Empress, Alfred, Vanilla, Victoria, and the brilliant new Dazzler. The catalogue is packed with excellent illustrations.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Exhibiting Vegetables.

Nearly two months will elapse before those who take an active part in the competitions for the many valuable prizes that are annually offered for vegetables at horticultural exhibitions will be in a position to store for a time their boxes and other appliances, and prepare a full statement of their gains and losses for the year. The autumn exhibitions have yet to be held, and, happily, at the majority of them vegetables receive liberal encouragement, and usually the contests are of widespread interest. The exhibition season, so far as the cultivators of vegetables are concerned, has advanced far enough to enable exhibitors to estimate with some degree of accuracy the results of their efforts, and for horticulturists who do not exhibit to formulate an opinion on the progress or otherwise that has been made in the presentation of vegetables to public notice. We need not refer at any length to the historical aspects of exhibiting vegetables, for the main facts are familiar to those who have paid some considerable share of their attention to the subjects. It will indeed be sufficient to remind our readers that thirty years or so ago vegetables were shown in such manner that they were invariably kept quite apart from the plants, flowers, and fruit, and that the tent devoted to them was a place to be avoided. Times wellnigh out of number have we been at exhibitions so well attended that every tent except that given over to the products of the kitchen garden was crowded to excess, while in the latter could be seen only the policeman or steward in charge, and a few exhibitors engaged, it may be, in counting up their gains, or enquiring why their products were placed so low down on the lists of awards. All this has happily changed, and instead of the vegetables being shunned by visitors, they prove so attractive that in many cases there is considerable difficulty in closely approaching the winning collections in the chief classes. In the olden days, if those of thirty years ago can be so described, cabbages, cauliflowers, and similar kinds were shown with the whole of their outer leaves, and of so large a size as to suggest a greater degree of suitability as food for cattle than for the table. Equally unsatisfactory was the manner in which potatoes, carrots, and other roots were presented to the notice of the judges, for they were usually staged with the whole of their leaves and a considerable amount of soil. By the time exhibitors had received lessons of considerable practical importance on the value of cleanliness and neatness, they had, by the manner in which the awards were frequently made, been encouraged to regard size as of primary importance. Hence it was that for a time products of a size wholly unsuitable for the table were generally to be seen at the exhibitions. This state of things has happily passed away, and those who have had some experience in exhibiting, or are conversant with the practice of exhibitors, are careful to select specimens of medium size, and to present them in a neat and cleanly state. Not only is this done by those who have charge of great gardens, but by cottagers, who for the most part are now well acquainted with the points that contribute to success in a close contest. No longer can it be said that exhibitions encourage the production of vegetables unfitted for the table, except in those instances, and they are few, in which the judges are not fully acquainted with the more advanced views that obtain with regard to the points of merit of the several kinds. The exhibiting of vegetables has not only contributed to the improvement in the methods of culture and the manner of showing, but it has brought into prominence the utility of some that are not generally known. While such kinds as beans, cabbages, cauliflowers, carrots, peas, and potatoes, and the various winter greens are essential in every household, the supplies should not, as is so generally the case, be wholly confined to them. Some education of the palate may be necessary to the full appreciation of aubergines, celeriac, salsafy, and scorzonera, but when this has been obtained, occasional supplies of these kinds will be highly appreciated for the agreeable change they afford. For this reason we were pleased to find that the Royal Horticultural Society has recognised the importance of increased attention being given to certain kinds not now in general cultivation, by providing a special class at their exhibition held during the past week. It was satisfactory also to see that the contributions to the class were numerous, and the products of much merit. The lesser-known kinds were also well represented in the remarkably fine gold medal exhibit arranged by Messrs. Sutton and Sons, which contributed not a little to the attractions of the exhibition. With reference to this gathering it was unfortunate that the two exhibitors in one of the classes were disqualified. As will be seen by our report on another page, a class was provided for nine distinct kinds, the object thereof being to illustrate vegetables that are in daily use, and possess the qualities most valued by cooks for table use. The kinds shown were such as are in constant request in the kitchen, and the specimens were of a quite moderate size. They were, indeed, similar to those in the winning collections in the class on previous occasions, and it was generally felt that if it was intended to adopt a different method of judging, the conditions governing the competition should have been so worded as to make this quite clear.

MR. REGINALD CORY.

Mr. Reginald Cory, whose portrait we have the pleasure of giving, is a striking example of the immense influence for good that an amateur horticulturist,

untrammelled by fashions, and possessing taste and judgment of a high order, is able to exercise on the gardening art. While taking an active interest in all the chief aspects of the garden, Mr. Cory's name is at the present time specially prominent for the splendid work he has accomplished in demonstrating the great value of the dahlia, in its multiplicity of forms and diversity of colouring, for beautifying the garden from the month of July onwards. The importance of this demonstration cannot well be overestimated, for times wellnigh out of number we have within recent years been told that dahlias are of but little utility in contributing to the charms of the garden, and, while they may be grown by cottagers and small amateurs, they are quite unfitted for gardens of the highest class. The expression of such views have clearly indicated the prevalence of a want of knowledge of the characteristics of the several sections of dahlias, or to a prejudice largely due to the cultivation of varieties for garden decoration that are suitable only for the exhibition stage. Possibly recognising this fact, Mr. Cory set himself the somewhat formidable task of proving to demonstration that not only may a goodly number of varieties be successfully employed in the production of colour effects, but are well suited to gardens of the highest class, such as those which form so glorious a setting to the stately mansion of Duffryn. For a considerable period dahlias have been grown in these gardens largely and with much success, and this year Mr. Cory decided to conduct a trial of garden dahlias on a sufficiently extensive scale to bring into prominence the varieties most suitable for the embellishment of beds and borders. The plan of the trial was so skilfully prepared and the details so admirably carried out, as to justify the trial being described as a brilliant success. It included between 7,000 and 8,000 plants, in nearly 1,000 varieties, and the effect produced by this enormous number of splendidly-grown plants has not been equalled, or indeed approached, at any period in the history of this valuable autumnal flower. It was part of the plan that the relative merits of the varieties should be determined by a joint committee of the Royal Horticultural Society and the National Dahlia Society, and this was readily agreed to by the two bodies. In recognition of the valuable services thus rendered by Mr. Cory, the President and Council of the Royal Horticultural Society, at a meeting held on the 9th inst., unanimously awarded him a Gold Flora Medal, this honour being all the more noteworthy from the fact that on one occasion only had the award of this medal been made, the previous recipient being the late Baron Schröder. To still further assist in the extension of the cultivation of garden dahlias, Mr. Cory presented to the Royal Horticultural Society early in the year a silver challenge cup, of the value of 75 guineas, for a display of the flowers of varieties specially useful for decorative effect, and the competition for this trophy resulted in a display of flowers of wondrous beauty. Within recent years the Duffryn gardens have been greatly extended and immensely improved, and the many features reflect in no uncertain manner Mr. Cory's great breadth of taste and his appreciation of the charms of all classes of ornamental plants suited to a great garden.

Sweet Peas.—In our issue of October 4 we shall devote special attention to the ever-interesting subject of sweet peas and sweet pea culture. Illustrations of new varieties will be given, and the more important articles will be "Autumn Sowing under Glass," by Mr. A. E. Usher, Ranston Gardens, Blandford; "Autumn Sowing Out of Doors," by Mr. R. B. Leach, Woodhall Gardens, Dulwich; and "Some of the Newer Sweet Peas," by Mr. Thos. Stevenson.

Twenty-first Reunion of Employees at Park Place.—At Park Place, Henley-on-Thames, Mrs. Noble recently held a very interesting reunion of her past and present employees. In response to her invitation some sixty of the former came down to spend the day, and formed a very unique gathering of men, to mingle with the present employees, some of whom have spent nearly 40 years in service at Park Place. At the luncheon the Rector of the parish presided, and some 150 persons were entertained. Proposing the health of Mrs. Noble and family, Mr Geo. Stanton spoke of the interest taken by Mrs. Noble in the gathering, and said this was the twenty-first occasion on which it had been held. Mr. Stanton spoke of the success of the young men who had passed through the gardens, and especially those who were away in various parts of the world. Mr. Odell briefly spoke on behalf of the past members, and said it showed the good feeling and kindness extended to all those who had the good fortune to come to Park Place that such a gathering should be held, and should reach its twenty-first anniversary. Mr. Powell, the head gardener, had arranged a floral welcome on the cricket field, where a hard-fought match took place between past and present members. Altogether it was a delightful and unique occasion.

Begonias at the Panama-Pacific Exposition.—We learn that Messrs. Sander and Sons, Lim., of St. Albans, and Bruges, are presenting five thousand tuberous-rooted begonias to the authorities in charge of the International Panama-Pacific Exposition of 1915. These begonias will be used by Mr. G. A. Dennison, who is chief of the horticultural section, around the Palace of Horticulture.

Protection of Wild Plants.—The Selborne Society continues to take an active interest in the protection of wild plants from the several agencies by which their numbers have been greatly reduced within the past quarter of a century or so. A meeting of the Plant Protection Section was held at Burlington House on the 19th inst. for considering the best means of effecting this laudable object, but a considerable diversity of opinion was expressed by those who took part in the proceedings. Dr. A. B. Rendle, the Keeper of Botany at the British Museum, who presided, said that much injury was done by school children collecting plants indiscriminately for nature study, and by hawkers grubbing up primroses and ferns for sale. As a check to the injurious results of the operations of children and hawkers, children should be fully advised as to the best methods of procedure, and hawkers should not be dealt with. It was certain, he said, that if there was no sale for uprooted plants there would be no inducement for taking them. In the neighbourhood of large towns many of the choice native plants suffered from the effects of smoke, and he urged the importance of enforcing the Acts relating to the smoke nuisance and the establishment of reservations in various parts of the country. Professor Boulger, in referring to modern nature study, said that evidently there was need to "teach the teachers." The foxglove, which was once abundant in Epping Forest, was now practically exterminated. Mr. G. C. Durce suggested the scheduling of wild plants for protection, as was done with birds, but said he was opposed to giving greater power to landowners under the law of trespass; Dr. A. B. Christian said that some effort should be made to draft a Wild Plants Protection Bill, distinction being made between gathering flowers and rooting up plants. We are not in favour of much additional legislation for the protection of wild plants, because the powers already possessed by owners and occupiers of land and the County Councils are sufficient to restrain the vandals that root up plants for purposes of gain. With regard to the destruction wrought by children engaged in nature study there should be no great difficulty in making them understand what they should avoid in obtaining specimens.

New Montbretias from Holland House Gardens, Clacton.—Mr. P. S. Hayward, one of our regular contributors, sends us a gathering of montbretias, all the spikes representing seedling varieties of his own raising. The flowers are of excellent colour, and the branching spikes indicate such robustness that we feel there is a good future in store for many of these new-comers. Mr. Hayward has been working steadily for several years for the improvement of montbretias, and several other races of hardy flowers.

Mr. John Heal, V.M.H.—Everyone was glad to find the veteran hybridist, Mr. John Heal, back at the Royal Horticultural Hall, Vincent Square, on Tuesday, September 23, after a long absence. Though he has not quite regained his full strength, Mr. Heal has made a remarkable recovery from the accident he sustained some time ago, when he was knocked down and very severely injured by an omnibus while returning home from Messrs. J. Veitch and Sons' nurseries at Feltham. Mr. Heal asks us to thank all those who have so kindly enquired after him during his illness.

American Gooseberry Mildew.—In common with other counties in which bush fruits are grown somewhat extensively, Huntingdonshire has experienced a severe attack of the American gooseberry mildew, and some of the growers have had their returns from gooseberries considerably lessened thereby. It is therefore gratifying to find from the report of the County Council's inspector that there has this year been a material decrease in the intensity of the attack. This decrease is attributed in part to the warm and comparatively dry weather during the spring, and in part to the greater care evinced in the pruning of the year previous.

Visit of the British Association to Burbage.—About a hundred members of the British Association recently visited the Burbage Experiment Station, near Hinckley, Leicestershire, where Major C. C. Hurst conducts many experiments on Mendelian lines. The visitors were much interested in Major Hurst's work among antirrhinums and berberis, as well as his experiments with pigeons, poultry, rabbits and horses. Some years ago Major Hurst took a keen interest in orchid hybridisation, and our readers will remember that in 1912 and 1913 he has conducted the National Sweet Pea Society's Trials of Sweet Peas at Burbage.

Epiphyllous Plants.—At one of the meetings of the Botany Section of the British Association, Professor W. H. Lang said that an epiphyllous plant was one which grew on the surface of foliage leaves of trees in tropical forests. The advantage which attached to this rather peculiar method of life was obvious. The difficulty of the small plant, especially in crowded forest vegetation, was to obtain sufficient

light, and the leaf of a plant was constructed so as to be as suitably as possible exposed to the light. But these little plants had to maintain their hold on a smooth surface, repeatedly washed by heavy rains, and they also encountered some difficulty in obtaining their water supply and food salts. The plants belonged to the algæ, lichens, liverworts, and mosses, and exhibited many features that fitted them to the situation in which they grew. Professor Lang illustrated his subject by actual specimens and by magnified photographs of the plants on the leaves.

Salisbury Gardeners' Outing. —The members of the Salisbury Gardeners' Society recently held their annual outing, starting at 8 a.m., and returning at 2.30 a.m. the following morning. This long day was spent in travel, and in visiting the Royal Botanical Society's Gardens, and the Zoological Gardens at Regent's Park. The flowers at the Zoo proved as interesting and far more attractive than the animals.

Tobacco Culture in England. —So successful have been the experiments made in the culture of tobacco in England that, although the Government rebate of 1s. 2d. per lb. duty on home-grown tobacco ceases with this year, the Development Commission have obtained a grant of £7,500 for the purpose of fostering this new industry. This grant will be distributed under regulations formulated by the British Tobacco Growers' Society. Mr. A. J. Brandon, of Church Crookham, Hants, who is the moving spirit in this new undertaking, estimates that either coarse or bright tobacco is a paying crop in certain districts, though a fairly costly one to work. He has 30 acres under tobacco this season, and last year, with 15 acres, he produced and sold 22,000lb. of tobacco, and paid nearly £3,000 in duty, one-third of which was returned in rebate.

New Demonstration Garden at Aberdeen. — Owing to the great success of, and the large numbers which attended, the classes in school gardening, given to school teachers by the Aberdeen and North of Scotland College of Agriculture, at Morningfield, Aberdeen, the facilities have become quite insufficient to meet the demand. To remedy this it has become necessary to seek for accommodation elsewhere, and to this end there has been acquired the field known as the Bishop's Park, Rubislaw, in the western suburbs of Aberdeen. At present used as nursery ground, the field extends to two acres, and has been obtained on lease. It is proposed to provide a small lecture-room to accommodate about 40 students, and other small buildings. The estimate of initial outlays for buildings and garden is over £600, and the annual expenditure will amount to a little over £170.

The Wild Flower Garden.— Speaking on the cultivation of wild flowers in the garden before the members of the Aberdeen Working Men's Natural History Society, Mr. George Reay referred to the wild flowers he had successfully cultivated in his own plot of ground, and the pleasure and instruction that he had obtained from them. The wild flower garden did not appeal to the florist in the same way as it did to the botanist. The two types of men were essentially different. Naturally, they might have much in common, but their outlook and object of study were widely apart. The florist loved to mould the plant to his preconceived fancies and ideas, bringing about some wonderful results. The botanist, however, probed deeper, studying plants as they were, and for what they were, and saw beauty and order in everything. Mr. Reay said that he had not specially set apart any portion of his garden for the cultivation of wild flowers. He found it advantageous to grow both garden and wild plants together. The arrangement appeared to harmonise perfectly, and the results obtained had been extremely satisfactory.

Chrysanthemum Society of America.—The twelfth annual show of this society will be held in the Art Institute, Chicago, on November 5, 6, and 7 next. The report of the eleventh annual meeting, containing as frontispiece a portrait of the society's President, Mr. Chas. H. Totty, has just been issued. In it we notice the President's address, the secretary's report, and balance-sheet, the scale of points for plants and for cut flowers, awards of the Floral Committee, special prizes, varieties distributed, and list of members. The membership roll strikes us as being rather a meagre one, for there are less than a hundred names upon it.

Ghent Chrysanthemum Congress.—The year 1913 has been a busy one for our friends the horticulturists in Ghent. In April there was the Quinquennial, largely attended by Britishers; in August there was the Floralies d'Eté; on September 8 and 9, the Pomological Congress was held, and finally there will be on October 25 to 28 a large Chrysanthemum Show and Congress, the programme and schedule of which can be obtained from M. Charles Pynaert.

A FINE DISPLAY OF DECORATIVE GARDEN DAHLIAS.

This attractive collection was exhibited at the R.H.S. Meeting on the 22nd inst. by Messrs. Carter Page and Co., who were awarded the 75-guinea challenge cup offered by Reginald Cory, Esq.

GARDEN DECORATION.

Modern taste is returning to an appreciation of the artificial style in gardening, after a period in which fashion decreed that the natural style should be held highest in favour. The wild garden possesses its own charm, but needs its own locality. To create it within sight of nineteenth-century buildings, iron railings, brick walls, trim fences, pagodas and pergolas, painted pavilions and boat-houses, or roads flanked by telegraph poles, if not lamp-posts, is to betray a serious lack of artistic sympathy. Its place is near fields and woods, of which it can be seen to be an improved portion; close by ancient ruins; shut-away tracts of moorland or common; slopes adjoining copses or pasturage; environs of bracken-clad glades or pine forests; any locality, in short, where the handiwork of man and the impress of civilisation is not too evident.

Near our mansions, villas, and cottages we may well make use of all those qualities that plants possess in addition to their naturalness, either original or through the florist's skill. The rose, with its myriad petals, may or may not be an improvement on the wild rose, as taste may decide, but the exhibition beauties of to-day are memorials to great horticulturists, just as the perfect marble statues of our galleries are an advance upon the flint carvings of our distant ancestors, memorials to famous sculptors, and proof of the progress made in Art. Wild flowers of our own land have been freed from undesirable forms and habits of growth; coarse "weeds" have become parents of extraordinary floriferous and bright varieties. Other countries have been ransacked, at peril to life, for foreign flowers willing to manifest their splendour where cultivated taste can pay their due meed of praise.

The neighbourhood of the English home should be adorned lavishly by employment of all the gardener's resources; the setting of plants in formal beds, in designs along borders, the pairing of trees and shrubs, the symmetrical training out of branches, is legitimate art, and reflects more credit on the owner than he will ever gain from imitating a hayfield, a common, or a wood.

When beds and borders are filled the pleasure-grounds can be further ornamented by making groups of pot plants, similar to those handsome displays that are seen in show tents. The semi-hardy greenhouse plants all benefit by open-air life during summer months, many of the more tender subjects can be safely used, and this placing beneath British skies of the tropical denizens that are noted for being the glory of far lands, is an honourable achievement. The pots should not be visible, not only because they have generally a discordant colour note, but because the mind cannot help shrinking from the evidence of restricted growth in the open air.

Greenhouses and conservatories in which most of the plants are grown in beds and borders are the truly artstic ones, and the pots admitted should be so hedged round by dwarf shrubs, ferns, flowering trailers, grasses, etc., that they do not offend the vision; but pots in the garden are always an offence to some eyes. It is easy to make up a sloped bed of cinders against a wall, sink the pots in this slug-resisting material, and thus build up a low bank of splendid flower and foliage. Plumbago capensis, blue and white; oleanders, tree fuchsias, immense trained specimens of ivy-leaved pelargoniums, abutilons, cannas, wigandias, schizanthuses, the purplish-leaved ricinuses, the blue-silver eucalyptuses, and the gigantic Nicotiana tomentosa that reaches a height of eight feet, are especially useful.

One charming effect that can be arranged is a raised border, surrounding a lawn, the adjoining paths to which are sufficiently wide to be encroached upon. Cinders are used on the gravel to form a narrow border coming nearly up to the grass level, either sloped up, if space permits, or levelled simply as an extension, and held in place by a miniature fence of green painted wood next to the walk. In these cinders pot plants can be sunk, as in the groups just advised; the finest specimens can thus be brought into the most visited portions of the garden.

Hardy plants in pots can be cordially recommended for similar employment, so gardeners may well prepare for another season. Canterbury bells, Campanula pyramidalis, carnations, Sweet Williams, anchusas, gaillardias, pentstemons, Brompton stocks, aquilegias, asphodels, erect clematises, coreopsis, delphiniums, gentians, impatiens, and lavateras occur to memory as attractive subjects for such groups or borders.

M. H.

WINTER SWEET.

Though in most parts of the country Chimonanthus fragrans is best grown on a south or west wall, it seldom looks so well as it does when grown as a free bush with branches sticking out in all directions. It may often be seen growing in this way in the warmer parts of the country and in sheltered positions. When too formally trained to a wall it has but little beauty as a shrub, even when in flower. It is grown more for its fragrance than for its showiness of blossom, beautiful though the latter is when closely inspected. The scent is pleasantly diffused when the flowering sprays are brought into a warm room. It lasts a long time in water, and may be cut before the flower buds have begun to open. If the flowering growths are cut to within two or three buds of the base, the cutting for decoration will to that extent serve the purpose of pruning the bush at the same time. As it is the young wood which produces the best blossom, we want to induce as much growth of this as possible, and, subject to the desired extension of the shrub, all remaining young growth should be cut back after flowering to within two or three buds of the base, at the same time doing a little thinning where necessary.

The mistake is sometimes made of growing this shrub in a soil which is either too moist or too rich, when it grows very luxuriantly but produces little bloom. To obtain the maximum amount of flower plenty of sun is necessary, with a soil rather poor than otherwise, and not too damp.

There is a variety called grandiflora which is somewhat better than the type owing to its flowers being larger and more open. It varies, however, both in robustness and in the character of the blossom, owing to the fact that it is often raised from seed in nurseries.

ALGER PETTS.

Origanum Tourneforti.—Some particularly attractive examples of this were shown at the meeting of the Royal Horticultural Society on August 26. In common with two allied kinds, O. Dictamnus and O. hybridum, it forms a very pretty plant when in flower, and is then very useful for greenhouse decoration. It forms a freely-branched little bushy specimen, whose slender shoots are clothed with hoary leaves, and thickly studded with clusters of flowers, in appearance suggesting miniature hops, but of a pretty pink colour, hence its popular name of Pink Hops.—T.

ARUM LILIES.

Few plants are so well adapted for indoor decoration as the Richardia, better known as the Arum Lily, to which flower the misleading English and Latin epithets of Lily of the Nile and Richardia æthiopica are also applied. This error in all probability owes its rise to a supposition that the plant was identical with the lotus of the Egyptians, a widely different subject and a true water lily, whereas the Richardia, although growing well when planted below the level of the water, is a marsh plant, and a native of South Africa, where it rejoices in the uneuphonious title of Pig Lily.

The value of the ivory-white spathes for noble floral arrangements is unsurpassed. The wide spathes, with their soft purity of tint and graceful curves, present a picture perfect in colour and form, as, poised on their tall green shafts, they overtop the drooping, glossy leaves. For church decoration arum lilies are in great request, since they are available in enormous quantities for the festivals of Christmas and Easter, when their large size and simplicity of outline render their individual form apparent, where smaller flowers present from a distance only a mass of white. In many sheltered localities in the south-west of England and in the south of Ireland arums are permanently planted out in the proximity of water with most effective results. In some cases they are placed in the damp soil around the margin of ponds and lakelets, and in others are planted at the edges of the pools, where the shallow water covers their roots to a depth of some inches. When in bloom in such positions they create a delightful picture. At Trelissick, in Cornwall, a lake is entirely surrounded with them, and early in June a couple of thousand blooms might be cut without their being missed.

When grown for the production of blooms under glass different methods of culture are practised by various growers, some planting them out in trenches of rich soil during the summer months, and others allowing them to remain in their pots and become thoroughly dry before repotting. Both plans have their advocates, who testify to the superiority of the course followed by them to the opposite method of treatment. Good results have doubtless been obtained by the followers of each system, but the thorough ripening of the roots is certainly more in accordance with the conditions experienced by the plants in their native habitat, where in the hot summer the soil surrounding the roots often becomes parched to a brick-like consistency, than the method of keeping the plants growing throughout the entire year.

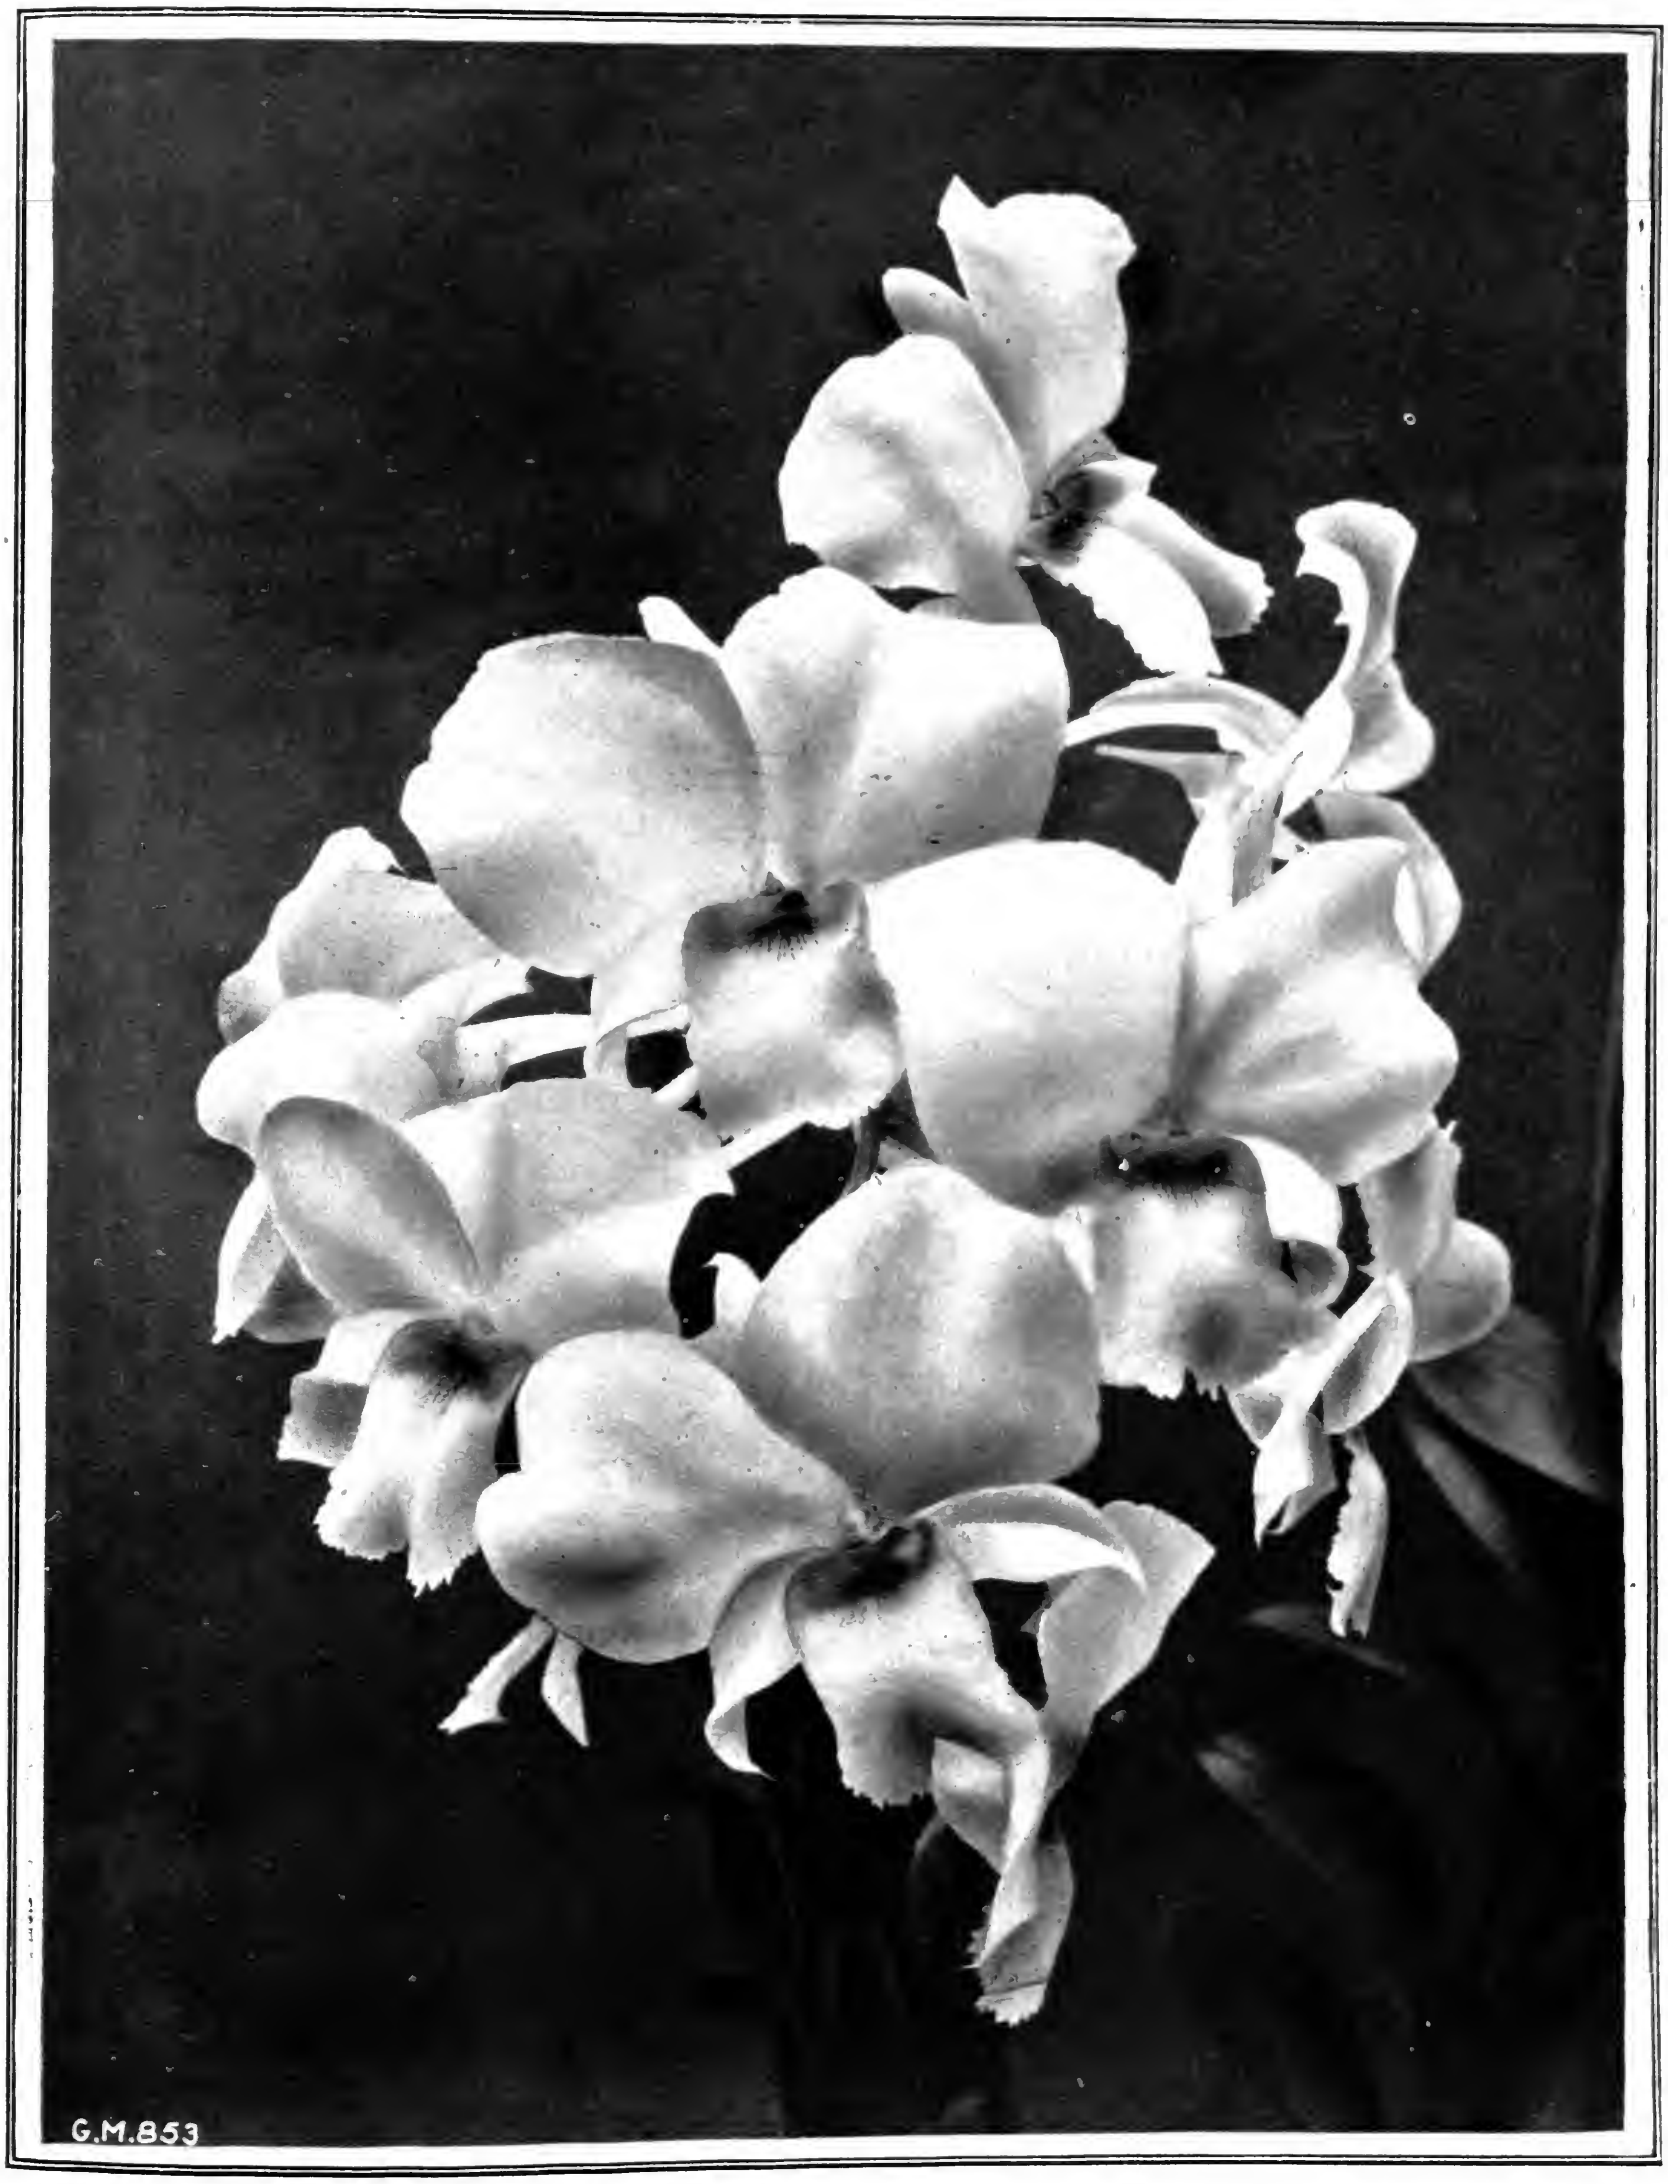
Where the system of permanent pot culture is adhered to, the plants are, in the south-west, placed in the open early in May with impunity, but in less favoured localities a position in which they may receive protection from late frosts is advisable. Water is given in lessening quantities until the leaves begin to turn yellow, when it is entirely withheld, and the pots are turned on their sides. In this position they are left until the end of July, when the plants are turned out, repotted into fresh, rich soil, and given a good watering. From this time they are not allowed to become dry, and in about two months' time are housed, a genial temperature being maintained around them, and a plentiful supply of water, with periodical applications of liquid stimulants afforded. Treated in this manner the plants will make healthy and vigorous foliage, and commence to throw up their blooms in November, producing their white spathes in quantity at Christmastide.

WYNDHAM FITZHERBERT.

DENDROBIUM DEAREI.

So many of the cultivated dendrobiums, either species or hybrids, flower early in the year, that the merits of those which bloom at other seasons are apt to be overlooked, with the exception, perhaps, of D. Phalænopsis and D. formosum giganteum. D. kinds, which are only a success when subjected to a long and well-marked resting period, during which they need a position in which they will be freely exposed to the light and very little moisture at the roots.

D. Dearei was discovered at Dinaget, one of the Philippine Islands, in 1882, by herewith illustrated before the Orchid Committee at the Royal Horticultural Hall, Westminster, on Tuesday, July 15 of the present year, a very great deal of interest was taken in it, and an Award of Merit granted. D. Dearei McBean's variety, has flowers of larger size than the



DENDROBIUM DEAREI McBEAN'S VARIETY.

Flowers pure white, with yellow marking on the lip. A.M., R.H.S., July 16. Messrs. J. and A. McBean, Cooksbridge.

Dearei usually flowers during July or August, and is a particularly beautiful species that requires fairly warm treatment. As the leaves last about a couple of years it is practically an evergreen species, and therefore it requires different treatment to the early-flowering deciduous Colonel Deare, but it is fairly plentiful also on the larger island of Mindanao. Although considerable numbers of plants have been imported on various occasions, D. Dearei has not exhibited much variation, hence when Messrs. J. and A. McBean, of Cooksbridge, placed the very beautiful variety type, of fine form and substance, pure white, save for the yellowish marking towards the base of the lip. On the spike illustrated there were a dozen of these blooms, which were so exquisitely beautiful that it was not surprising the variety should have attracted much attention.

A DAY IN THE FRASER VALLEY, BRITISH COLUMBIA.

I have been asked to give a description of a day's sight-seeing in the Fraser Valley, and I hope it may interest some of your botanical readers, as the flora of that district is very rich.

The Fraser Valley is situated along the wonderful river of that name, from Vancouver to Chilliwack, which is the terminus of the British Columbia Electric Railway, a distance of about 65 miles. Having inspected New Westmnster, where we had to change cars, we crossed the river on a well-constructed bridge, the river there being very broad and with a strong current. All along the railway clearing, which has been cut through the bush, the vegetation is luxuriant and fresh, with no dust, the soil chiefly a peaty bog. There are quantities of ferns—bracken, the lady fern, and a polystichum—all several feet in height; skunk cabbages, a plant with plain, very broad leaves, and large, bright yellow, arum-lily flowers, with a horrible odour, hence the name; Mitchellia repens, the Squaw Berry, and some pretty rhododendron-like shrubs which I did not know.

Spiræas of three kinds were seen flowering luxuriantly against great bushes of scarlet-berried elder, and there were acres of foxgloves, purple and white. Masses of the Salmon berry, with its delicious raspberry-like fruit, the cut-leaved bramble, and the blue berry, were all growing in the wildest profusion.

Great clearings had been effected by fire, and there the willow herb was growing and flowering as in a great garden, making the waste places a thing of beauty; they call it here the "Fire Flower," as it always appears after a fire. Clumps of a small orange lily looked beautiful, and made me remember that it was the 12th of July.

On the stumps of trees, amongst decayed bark and dry banks, the Gaultheria, with its pretty rosy lily of the valley-like flowers and glossy green leaves, grew in such masses that I at first failed to recognise an old favourite in so congenial a home. Great tufts of the Crown Imperial seemed to have flowered well; I was told they were quite common here. The young shoots from the cut-down maples were very beautiful in their colouring against the dogwood bushes and other shrubs which grow in profusion there.

For miles and miles we saw nothing but wood or bush; the trees grow so closely together and are very tall, with scarcely a branch till near the top, and with little difference of girth; the undergrowth is so thick and dense that you cannot see daylight overhead, and one can well imagine the havoc of a forest fire. We saw thousands of blackened, distorted trees, thousands of stumps, and still thousands of tall, straight, and grey trees, with only the branches gone, looking like sorrowful monuments; and here and there enormous giants of the forest several yards in circumference. The trees are principally the red, white, and yellow cedars the hemlock spruce, the scrub pine, birch, maple, and white poplar.

The stations are primitive in the extreme, while such names as Abbotsford, Huntingdon, and Brentwood suggest a remembrance of the old country; while Jackman, Jardine, Gifford, Dension, and Sullivan may have been the pioneers of the valley. There are several lumber camps and saw mills, many farms and poultry runs, and horse-breeding establishments, but the most fertile spots for farming and market gardening are Sumas and Chilliwack. Here, in a dip of the valley, the soil is good and rich, with very few trees, and, sheltered by the surrounding mountains, there is an even temperature, and everything grows in profusion.

We had a pleasant motor drive round Chilliwack, and were shown the hop-fields grown by a Kentish man, and with such success that the future of hop-growing may be assured; there was also a market garden of about three acres for salads, tomatoes, cucumbers, and such wonderful roses and sweet peas, all of which find a ready market.

Every bungalow has its flowers, and each person has his own ideas of building and decorating, and as the homes are all of wood, some are very picturesque. A pretty sight was a long row of blue delphiniums against a white verandah. Along the banks of a river and the fringe of the woods the mock orange (Philadelphus) and the Deutzia, both indigenous to Sumas, scent the air for a long way, while the maidenhair fern, from 1 to 2ft. high, grows like a weed. Here we saw several meadow larks, birds about the size of a thrush, and with a peculiar note. Good shooting is to be had in the valley, permission, of course, being asked of the landowners. You can shoot anything in season, deer, pheasant, partridge, rabbits, and grouse. A gun licence costs $2\frac{1}{2}$ dollars. Very good fishing is also had in the river, but the best and principal fishing station is at the mouth of the Fraser River, the home of the Sockeye Salmon, the most delicious of the food fishes of the world.

This is the quadrennial big year, and this is the first month of the three, for the salmon fishing, and hundreds of boats are employed, chiefly motor boats, and many engaged by Japanese. Steveston is the town of the canneries, located at the mouth of the river, and here is a great industry for a few months, the price realised from the salmon fishing on the Fraser alone being placed at a million and a half dollars. There are many kinds of salmon, viz., sockeye, red springs, white springs, chums, pinks, and cohoes.

On returning in the evening we had the unpleasant experience of running through a dense cloud of mosquitoes. The conductor opened all the windows and front door of the car, and calling out, "Mind your hats," thus rushed a strong current of air through to get rid of them, but many passengers were severely stung.

The sunset on the valley was grand; the mountains all along capped with snow, the river like a great sea, with the melting of the snows flooding the adjoining lands to within a few feet of the railway track. On the car rushed, past great trees like tall sentinels, and a glorious sunset flooded the valley. It was a day's excursion not to be forgotten.

M. WEBSTER.

CHRYSANTHEMUMS.—For full instructions on the Culture of Chrysanthemums in beds or borders for garden or greenhouse decoration, read the Second Edition of CHRYSANTHEMUMS FOR GARDEN AND GREENHOUSE. by D. B. Crane, price 2s. 6d. net; or by post 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

BULBS FOR NATURALISING.

The merits of early-flowering bulbs for naturalising in masses in the pleasure grounds and wild gardens are so generally recognised as to render this method of planting increasingly popular. There are few gardens of any repute where this form of planting is not largely represented, and in a great many instances the effect created is quite equal to that obtained at any other season of the year, while not infrequently the display of bulbs makes the springtime the most attractive of the four seasons.

It is hardly necessary to emphasise the importance of planting bold masses of one variety in each group, for the effect obtained under such conditions is certainly the most telling and imposing. Let the groups be of irregular outline in the wild garden, as though the flowers had sprung up naturally, and plant rather thickly.

Where the soil is light in texture planting can very well be performed with one of the patent bulb planters made for the purpose, or holes can be made with an iron bar in which to insert the bulbs; but in heavy, retentive soils this practice is not a good one, as the holes are liable to hold water during the winter, which may cause the bulbs to decay; moreover, the soil around the holes is usually exceedingly firm, which prevents the bulbs from rooting freely. After making holes with a bar, a little prepared soil should be placed in the bottom, and the bulbs planted about four inches deep.

When the soil is heavy and retentive, it is preferable to break it up with a spade, and then replace the turf after planting. In our heavy soil I find this plan answers very well, and the little extra time taken to do the work is fully repaid by better results. It is preferable to plant bulbs as early as possible, so as to allow them to commence growth at an early date, as under such conditions the results the first season are much improved.

For naturalising in large breadths of grass, or beside woodland walks, no bulbs equal the narcissi, provided the more vigorous kinds are chosen. Emperor is one of the grandest varieties for the purpose, as it grows with vigour, and a large colony makes a striking feature. Empress is also good, and may be planted in close proximity to the above. Sir Watkin is recognised as being invaluable for massing, and Horsfieldi and Princeps are both useful.

The old double daffodil (Telamonius plenus), with its rich double blooms, creates a particularly striking effect in the distance. Golden Spur is an attractive variety, and blooms in advance of most daffodils. Maximus, Henry Irving, Autocrat, Madame Plemp, Grandis, Barri conspicuus, and poeticus ornatus can all be recommended for planting in the grass. Many others might be chosen to create variety where space permits, and for planting on sloping ground Waterwitch and Mrs. Langtry are especially desirable. These varieties look very well naturalised in broad breadths of Erica carnea, and the contrast in colour is very pleasing.

Some of the smaller bulbs, such as snowdrops, aconites, crocuses, and scillas, are very beautiful seen in large masses, especially in the woodland; while the merits of the colchicums or meadow saffrons must not be overlooked. Of these C. speciosum, C. autumnale, and C. Parkinsoni might be grown.

Hyacinthus candicans, Lilium martagon, Fritillaria imperialis, and F. meleagris are all suitable for naturalising in the wild garden, and bold groups are very beautiful when in bloom.

J. GARDNER.

Batsford Park Gardens.

TULIPS IN FIBRE.

Although the cultivation of bulbs in fibre has now obtained a firm hold upon the flower-loving public, the free use of tulips in this connection is a matter of quite recent date. Last spring numerous exhibits at various exhibitions demonstrated the suitability of tulips for culture in fibre in ornamental bowls, and many readers will remember how successfully Messrs. R. H. Bath, Lim., of Wisbech, showed Darwin tulips, so grown, at the Royal Horticultural Hall. Mr. W. Howe, gardener to Lady Tate, Park Hill, Streatham, has also shown in first-rate fashion how suitable tulips are when grown in fibre, and the accompanying illustrations represent wide green pots of flowers staged by him in a prize-winning stand at Westminster.

These references are given because tulips are generally considered to be more difficult to manage in pots than either hyacinths or daffodils, but there is ample evidence to show that they present no special difficulties when placed in fibre, even in undrained pots or bowls. There are a few points to bear in mind, however, and one is that a bowl less than six inches deep is not suitable for tulips, though suitable for other bulbs, because a deeper root run seems essential, and under general treatment many tulips go "blind" if grown in shallow bowls. The fibre must be moist, but not wet, and should be placed over a small layer of broken charcoal and crushed shell. Tulip bowls must be well covered, and when rather shallow, wide bowls are used, instead of the deeper pot-shaped ones, it is a good plan to mound up the fibre over the bulbs, so that at the centre it may be an inch higher than at the rim.

The first fortnight in October is a good time to put tulips into fibre. If placed in a cold frame, covered with fibre, and left until the end of the year, a good root system will be produced, provided the material does not become dry. Failing a frame, place the pots or bowls of bulbs into a cool, dark cellar. To place tulips in a warm, dry cupboard is to court disaster. After a good watering, when the fibre has been thoroughly soaked, lay the bowls on their sides to allow surplus moisture to drain away; this advice is chiefly for amateurs who do not fully comprehend the niceties of "too wet" or "too dry" as understood by the professional gardener.

When growth begins ample light and a warmer position are necessary, and unless early flowers are needed a cool greenhouse or one slightly heated will prove a suitable place in which to bring the tulips into bloom.

Good early tulips for this clean method of culture are Colour Cardinal, Duchesse de Parma, Fabiola, Keizerkroon, King of the Yellows, La Grandesse, La Reine, Prince of Austria, Rose Gris de Lin, Rose Luisante, Thomas Moore, Van den Neer, Vermilion Brilliant, and White Pottebakker. Among the Darwin and May-flowering section good varieties are Bartigon, Clara Butt, Dream, Europe, Erguste, Isis, Inglescombe Pink, King Harold, Le Rêve, Maiden's Blush (or Picotee), Mr. Farncombe Saunders, Pride of Haarlem, Suzon, White Queen (La Candeur), and William Copeland.

Rivina humilis.—Among the berry-bearing plants that need a warm greenhouse for their successful culture must be included this Rivina, whose racemes of bright red, currant-like fruits, form a very cheerful feature at this season. The plant itself is easily propagated by seeds or cuttings, and will grow in ordinary potting compost.—T.

PEACH AND NECTARINE TREES AFTER FRUITING.

In sunless, cool summers the ripening of the wood of the current year's growth of peach and nectarine trees is a very important matter. Frequently trees have come under my notice that have been well managed until the fruits have been gathered, and then neglected. All lateral growths were removed while very small, so as not to exclude air and light from the fruits. This was good treatment, beneficial to both trees and fruits. When the latter were gathered all interest seemed to have ceased, and the laterals were allowed to grow and form a thicket; and no thought was given to the watering of inside borders. No, water could be applied later on, when the leaves had fallen, and the pruning could be done.

An experienced and thoughtful cultivator does not so treat his trees: they have an interest for him at every season and during every week of the year, and he knows how to manage both the vigorous young specimen, and the old one also, which need judicious feeding and careful cropping. I saw a grand peach tree the other day which was bearing a medium-heavy crop, but one could not see through the branches; they were so thickly-grown together and so numerous. As regards the ripening of the shoots required to bear the crop next year it could be seen that valuable time was being wasted.

Not only should the sub-laterals be constantly pinched out while very small, but every branch not required for service next year should also be cut out very soon after the crop has been gathered. The foliage should also be kept quite clean by occasional thorough syringings, and, in the case day must be ample, and the borders liberally watered when the soil needs it. Even outside borders should be well watered before the soil becomes really dry, as, in many instances, was the case a short time since. G. B.

WINTER CUCUMBERS.

To keep up a steady supply of these fruits throughout the winter months, September must be devoted not only to the preparation of the plants, but to thoroughly cleansing the pits where they are to be grown. It is useless to attempt cucumber culture if filth or insects are allowed to remain. I prefer 12-inch pots for winter cultivation, rather than planting out, placing fermenting material round the pots if necessary; but whether culture in pots or planted out is followed is a matter which each grower must decide for himself, his guide being the adaptability of the house and the amount of fire-heat at his command.

Keep a healthy stock of young plants in readiness, and a quantity of well-turned fermenting material in reserve. Avoid too much moisture as the days shorten and the sun declines in power, and, where possible, do not put out all the winter plants at once.

Warter Priory, York. F. JORDAN.

COTTAGE TULIP LE RÊVE.

Grown in fibre by Mr. W. Howe, Park Hill Gardens, Streatham. Colour satin-rose, with orange shading. A very handsome variety.

VARIATION IN THE COMMON POLYPODY.

Although naturally, as an ardent student of our British fern varieties for more than thirty years, I have seen many collections in which the above species in its numerous varietal forms has been well grown, and the particular character of each has been well developed, a recent visit to two collections—viz., those of Mr. T. E. Henwood and of Dr. F. W. Stansfield, both of Reading—have literally astounded me as to the capacity of development which may be induced by perfect culture of this species.

EARLY SINGLE TULIP VERMILION BRILLIANT.
Grown in fibre by Mr. W. Howe, Park Hill Gardens, Streatham.
Colour vermilion-scarlet.

As a rule, we find the varieties or "sports" accommodated in pots or shallow pans but in both these collections they are growing in beds protected, in the case of Dr. Stansfield, by a large ordinary frame, and in that of Mr. Henwood by a greenhouse. In both practically all the varieties of value were present, and growing with such luxuriance that the fronds not only formed bushes, but where, under pot or pan culture, they are rarely more than a foot high, here, in many cases, they were double that length, or even more, while the division and subdivision of the divided and plumose varietes were carried to an extent which I have never witnessed elsewhere.

To deal with Mr. Henwood's collection as permitting of a more comprehensive and effective view than that obtainable under frame culture, I found it installed in a wide bed extending along the whole side of the greenhouse. The soil was deep, and composed of an admixture of friable loam and leaf-mould, the latter largely predominating, so that the compost was very free and open, thus permitting the travelling rhizomes of the species to penetrate deeply and travel freely. Each specimen or variety had obviously been planted sufficiently far apart to prevent, at any rate for some time, any crowding or competition between them. The salutary effect of this, and of the loose compost itself, was evidenced by the immense size of the fronds to which I have alluded (P.v. omnilacerum, Oxford, being by actual measurement 30 inches, surely a record for the species), while the ample light afforded by the clear glass, only shaded when necessary from burning sunshine, prevented them from being drawn up and consequently assuming a decumbent habit foreign to the species in most of its varietal forms.

Seeing such results, the question to the would-be cultivator is, What is the secret of such success? The answer lies not merely within the greenhouse itself in which it is exemplified, but also in the garden in which it exists. Here are not only ferns but also many flowers, and these the expert horticulturist recognises at once as all of the best and choicest species and forms. Not a trace of weeds appears, the soil everywhere is obviously rich, and the plants in it are expertly and evidently liberally treated, and kept in such order as enables them to display their flowers to the best advantage. I also noticed, inside the greenhouse, that a peculiarly congenial moisture pervades not merely the soil but the atmosphere by frequent flooding of the paths, the benefit of which is shown also by a tufa bed on the right-hand side filled with magnificent specimens of the Hartstongue varieties, which do their best to rival their opposite neighbours, which form our special theme. Above all, there struck me, as a contrast to many collections I have seen, the absence of any traces of insect depredation or defilement, due undoubtedly to constant watchfulness and the immediate use of insecticides should traces of such pests present themselves.

I am indebted to Mr. Henwood (of carnation and auricula renown) for the appended list of varieties, which show how greatly the common species of the hedgerows, old walls, and trees, has contributed by "sports" to the élite of our handsome British fern varieties, all but a very few being the original form as found wild, the species thus owing little to selective culture. In conclusion I would point out that the species in question is perfectly evergreen, the fronds remaining fresh and verdant until the next growing season. Curiously enough, though the normal species and many of its varieties rise fairly early in the season, all the plumose or "cambricum" section defer rising, as a rule, until July, when they resume growth rapidly at a time when most of our native species are fully developed, thereby extending the interesting season materially.

CHAS. T. DRUERY, V.M.H., F.L.S.

Eranthis hyemalis.—Close-planted beech-woods are admittedly difficult positions to plant, and scarcely invite success with bulbous plants; yet it is under such conditions that the little winter aconite luxuriates. Under the dense leafage of the beech, little ground vegetation can exist, as the beech roots ramify over the surface in all directions, and on a shallow chalk soil the ground is usually bare. Planted, however, with the winter aconite (Eranthis hyemalis), the naked surface becomes a carpet of green and gold in January and February, and so freely does it naturalise that each year in spring can be counted tens of thousands of seedlings around the parent plants, the majority of which come to maturity. Dry tubers offer a ready means of introducing this hardy subject, which, if planted at nine inches in the first instance, will soon close in together and form an impenetrable mass of leafage and flower. —T. S.

HARDY CALCEOLARIAS FOR THE ROCK GARDEN.

It is not generally known that there are a few calceolarias which are hardy enough for standing our winters in the rock gardens of the greater part of the United Kingdom, even if we eliminate a certain number which are sufficiently enduring to survive in the warmer districts of the south, which are mild indeed compared to those in other parts. These flowers are generally highly appreciated by their owners, and by visitors to their gardens, and are well deserving of the notice of the lover of alpine flowers.

Calceolaria Golden Glory.

In the first rank of all these we would place the lovely hybrid slipperwort called Calceolaria Golden Glory, one of the finest introductions of recent years for the rock garden, or even for the choice border where hardy alpines are grown. This is a delightful plant, with nice foliage, reminding one somewhat of that of one of its parents, C. plantaginea, but prettier in every way. It has lovely yellow flowers in clusters, and grows some six or ten inches high. It is very easy to cultivate in any open soil, and is hardy in most parts of the three kingdoms. C. Golden Glory is propagated by division, and can also be raised from seeds, packets of which are procurable for sixpence or so, and should be thinly sown in pots of very sandy soil, and very slightly covered with fine compost of the same kind. A square of glass and a piece of brown paper ought to be put over the pot, and watering very carefully performed. As soon as the seedlings begin to germinate, remove the glass and paper, and give air carefully. Prick out in good time, and, after growing on in a frame or cool greenhouse, plant the seedlings out. Spring is the best time to sow the seeds, so that the young plants may attain some size before the winter. If they are very small they ought to be wintered in a frame.

Calceolaria plantaginea.

The plantain-leaved slipperwort is always rather a scarce plant, this being due to the difficulty some experience in establishing it. When once it takes to a special place it will thrive, however, and, as it is fairly hardy, it should be more frequently met with. It is a handsome plant, with large, deeply veined and wrinkled glossy leaves, and pleasing flowers of a nice yellow. It is from six to nine inches high. I find that it thrives best in a dry and rather sandy part of the rock garden, and in full sun. I have never seen it seeding with me, but have found that it increases readily by division in spring, or after flowering is over. The plant is also increased by means of root cuttings about an inch long, taken in March or in late autumn, and put in sandy soil under glass. This calceolaria is apt to suffer from excessive wet in winter, and ought to have a well-drained soil and a sunny position. It flowers in June and July.

Calceolaria polyrhiza.

This is a curious little creeping slipperwort, well called polyrhiza, or "many-rooted." It runs beneath the surface, sending up its growths freely, and, when left alone, forming a close mass of its small leaves, whence arise singularly formed yellow, spotted flowers. It is amazingly easy to grow, and a little bit planted in spring or summer will soon make a good clump. It is said to be a lover of a bog or moist place, but this is not essential, and the writer has a good mass which is in a dry and sunny spot. It is readily increased by division, and will probably be easy to multiply by root cuttings, but it is hardly needful to resort to these, as it increases so rapidly at the roots itself.

Calceolaria Kellyana.

I am referring to this now, as a handsome and scarce plant which is in existence, but of whose whereabouts at present the writer is unaware, although he cultivated it for some time many years ago. It was raised in Edinburgh more than seventy years ago. It has pretty yellow flowers with crimson spots. From its general appearance it seems to have C. plantaginea as one of its parents, but I have not found it so hardy. It blooms in summer.

Calceolaria violacea.

One can only recommend the violet slipperwort for those who live in favoured places, or are prepared to winter it under glass. It grows from eighteen inches to two feet high, and has lovely pale blue flowers spotted with violet. It blooms for a considerable time in summer and autumn, and is increased by division or cuttings. It loves a sandy loam.

Such are a few slipperworts deserving of consideration from the lover of rock garden plants. S. ARNOTT.

SWEET CHERRIES IN SCOTTISH GARDENS.

(Continued from page 689.)

Planting and Training.

It goes without saying that in districts subject to abnormal rainfall, or that have a heavy retentive soil, much greater care is necessary in respect to the preparation of the respective sites, than obtains where conditions considerably the reverse prevail. If burnt earth, wood ashes, or lime rubble are at hand in quantity, liberal supplies of any one, or even a mixture of all, applied to the whole plot or border, but particularly over a radius which the roots will eventually occupy, would prove very beneficial for a long period. The cherry, too, in comparison with other kinds of fruit trees, is somewhat surfact-rooting; hence, while in northern parts it may be advisable to keep the roots on or but very slightly below the natural level of the surroundings, ample coverings of soil should be given, thus forming a mound sloping from the tree stem.

After-culture by way of surface movement is best accomplished with the hoe, or if a fork is employed, very light turning of the compressed surfaces, due to its being trodden upon, or to natural agencies, will suffice. As early crops of vegetables or strawberries usually, in their season, occupy such favoured situations, a clear space of at least three feet from the wall should be reserved for the tree roots, which in course of a few years as the roots spread outwards may be still further increased. The fan method of training is most fitting, as should any untoward event occur, by way of breakages of branches or injury by disease, in after years the consequent gaps thus formed are more easily made good by training therein young shoots than is possible under any other method. Though but little addicted to diseases or attack by insects, gumming of the spurs and branches, and visitations of black fly sometimes take place. It behoves everyone when purchasing the young trees to see that the branches are free from injury by way of bruises, and that the point of union is completely healed, forming a smooth and evenly-barked stem, or trouble may arise at the outset, and the tree, after a few years of care and labour, leaving out loss of time, may have to be discarded.

Damage accruing through injudicious pruning, often the neglect of perfoming this in time, or any unintentional blow from a hammer when nailing; and, perhaps, more than any other, the strangulation of the fast-swelling branch by the pressure of stout cord used to secure it to the wall or other support, is always possible. The remedy for the latter is obvious, while as to pruning, if summer pinching were as much as possible substituted for this there would be less need for using the knife freely, and even then carried out early in autumn, while a good portion of the foliage still adhered to the shoots. Young trees are best allowed a year of unrestricted growth after planting to encourage root action.

When received the trees will, if fan-shaped, have from six to eight main branches, springing from about a common base. The former number is ample from which to form the structure of the future tree, hence if more numerous the weaker may first of all be closely cut away. The six remaining, three on each side of the stem, may then be roughly placed in position, and be shortened to within twelve or eighteen inches of their base, making the severance close above an outward-pointing eye or bud. Thinly-disposed branches are more conducive to fruitfulness, and if a tree is well furnished with fruiting spurs, it is best left alone as regards pruning in winter, shortening the leading branches when the buds show indication of sap movement in spring to ensure further laterals for training in to form the tree and to cover the available wall space, which may be little or much, and the number of leading shoots of corresponding necessity and importance.

Varieties.

Choice varieties that have proved good in quality, productiveness, and generally adaptable to the Scottish climate comprise: Early Rivers, which, compared with many others, is a modern introduction, but so well has it been received by growers, owing to its free-bearing and cluster-fruiting propensities, that it is established in most gardens. May Duke is not considered a high-flavoured fruit, and is less fleshy than some, but being hardy, early to ripen, and seldom missing a crop, it holds an undisputable position. All the bigarreaus are worthy of cultivation, more particularly Bigarreau Napoleon, a large yellow fruit flushed with red, of rich aromatic flavour. It is hardy, and will thrive in any form of training or aspect. Black Tartarian has very large fruit, which, as the name implies, is of very taking appearance, fruiting freely against an east or north wall. Elton, a mottled fruit of fine appearance and high quality, and one most likely to succeed in bush or standard, form, where this style of growth can alone be complied with. Archduke, large dark-red fruits with shining skin. Knight's Early Black. One of the best early-fruiting varieties known; the tree is vigorous in growth, attaining a larger size where space is afforded it. The very old sorts, White Heart and Black Heart, are still among the foremost for bearing and quality. J. DAY.

Watsonia Meriana O'Brieni.—This is a pretty bulb from South Africa, whose spikes of flowers of the purest white are borne during the summer months. From three to five bulbs in pots, five to six inches in diameter, are very useful for many decorative purposes. Of late years considerable numbers have been imported during the period in which they are dormant.—W.

ROSES IN SEPTEMBER.

Here, in Mid-Sussex, we started the month well with a most welcome and steady rain of about twenty-four hours' duration. With roots and other growing crops sadly in want of water, and the corn almost all carried, there has seldom been a more promising outlook than the present, providing we do not get a return of the mid-August experiences, when we had more than one frost, followed by excessive heat in the day.

Favourable as the general prospect now is, I do not think any crop can be more so than our roses for late autumn flowering. Those who have kept the hoe going freely, and either mulched or fed their growing roses with artificial manures, should now reap extra benefit from showers that fall.

It is too late to feed to any advantage now, unless it be by applying some liquid manures that would be assimilated at once. Keep a sharp look-out for mildew, now we are having such sudden changes of temperature, and so much young growth is in evidence. It is quite useless to delay and then take strong measures which cannot be in time to stop the ravages of the disease, nor used without injury to the foliage. The splendidly spreading trusses of some late bloomers will produce a grand and continuous show of flower, and it often happens they remain in blossom all through the present month, and even later, as the succession of young buds develops.

Make a note of the varieties that do well in your district, and procure some of these for any space that can be spared. There is much force in selecting roses suitable for certain districts, but the following are almost certain to do well wherever roses can be grown at all, and be particularly useful in the autumn months: Frau Karl Druschki, Mrs. R. G. Sharman Crawford, and Victor Hugo from the hybrid perpetuals; Augustine Guinoisseau, Betty, Caroline Testout, Countess of Derby, Duchess of Wellington, Edu Meyer, General MacArthur, Gustave Regis, Jacques Vincent, La Tosca, Lady Ashtown, Lady Battersea, Madame Ravary, Mrs. A. R. Waddell, Pharisaer, and White Killarney from the hybrid teas; and Corallina, Mrs. B. R. Cant, G. Nabonnand, Peace, Lady Roberts, Madame Antoine Mari, Madame Charles, Madame Jean Dupuy, Marie Van Houtte, Molly Sharman Crawford, Souvenir de Pierre Notting, and Rubens from the tea-scented section.

Then we have Arthur R. Goodwin and Rayon d'Or from the newer class of pernettianas, also the dwarf and thoroughly perpetual-blooming polyanthas, more especially the three varieties Jessie, Phyllis, and Mrs. W. H. Cutbush.

Have readers noticed the lengthened display of blossom upon many of our hybrid Wichuraianas? In my own case we have quite a show of such as Dorothy Perkins, Christian Curle, Hiawatha, and especially Delight and Minnehaha are simply charming, and promise to remain so for some time. A climbing or pillar rose that keeps much longer than most is American Pillar. I am much pleased with the all-round behaviour of this grand single, with its deep green and massive foliage, that has never given me any anxiety as regards mildew, red rust, or other diseases. From first to last it is invariably clean and healthy-looking, while the immense trusses keep up a succession of bloom for a long time, which will soon be followed by small, bright scarlet heps.

The rugosas generally are already very showy with their medlar-like heps, those of Rosa rugosa atropurpurea being particularly prominent and bright. The heps and autumn-tinted foliage of this section make them well worth growing independently of their extreme hardiness and early blooming.

I would advise the careful examination of buds inserted last summer. The present rains will encourage prolonged and vigorous growth that is apt to result in a more than usual swelling of the stock, consequently some slight loosening of the tie will be necessary. This is very quickly and effectively done by passing the point of a sharp knife down the tying material on the opposite side of the rosebud. Only just cut through the tie, and when there appears danger of constriction.

Those who contemplate grafting any roses during the coming winter months should lift and pot up some stocks ready for the purpose. Use small pots, good compost, and plunge in ashes or suitable material three or four inches above the stem. This will not only keep all free from frost and drought, but will secure a healthy and softer bark upon which to put the scion or graft, with the effect of quicker callus and junction.

Send in your orders for roses. It is better for both vendor and purchaser to make early arrangements. One has also the advantage of trying elsewhere for any specially-desired variety should the first seller not have it, or be already booked forward.

ROSARIAN.

A BEAUTIFUL BOWL OF ROSES,

For which Mrs. Courteney Page, Enfield, was awarded the first prize at the N.R.S. Metropolitan Show. The variety is Kaiserin A. Victoria.

A BOWL OF ROSES.

At the National Rose Society's Metropolitan Exhibition, held at Regent's Park on July 4, the numerous classes for the artistic display of roses formed a very large and interesting feature. The section was open only to ladies, and it was all the more interesting, because the idea kept in view was the arrangement of roses for the decoration of the home. One especially successful class was for a bowl of exhibition roses, and the competitors admirably demonstrated the fact, so often set out in these pages, that exhibition flowers of exhibition varieties may be disposed artistically. Some capital exhibits were set up, but the first prize bowl was especially fine, and very few visitors cavilled because the decision of the judges was in favour of Mrs. L. Courteney Page, Earldoms, Ridgeway, Enfield, whose grouping of Kaiserin Augusta Victoria we illustrate herewith. Other delightful exhibits in the same class consisted of Mme. Melanie Soupert and Mrs. G. Shawyer, representing these varieties in fine form, and deftly disposed by Mrs. E. Burnett and Mrs. J. Bide respectively.

POETAZ NARCISSI.

Just about a year ago (G.M., September 28, 1912, p. 743), I drew special attention to the merits of the Poetaz Narcissi, and it is with not a little pleasure I return to the subject again, particularly because the varieties of this race are such excellent plants for pot culture and for planting in fibre in ornamental pots and bowls.

As the Poetaz Narcissi are steadily growing in favour, questions are being asked concerning their origin, and the answers vary with the knowledge of the person questioned, and often there is a touch of inventive genius found in such answers. It may be as well therefore to again make it clear that for all practical purposes the poetaz group is of Dutch origin, and that the beautiful varieties we now enjoy were almost all raised by Messrs. Van der Schoot and Sons, Mr. R. Van der Schoot being, I believe, "the chief conspirator," and the gentleman who mated Tazetta varieties with Narcissus poeticus ornatus many years ago at Hillegom. The hybrid name of the race at once suggests its origin.

Some of our British raisers have turned their attention to poetaz varieties, and Mr. Engleheart has already given us Orient, and Mr. P. W. Williams is responsible for Scarlet Gem, a red-crowned, apricot-yellow variety that does not appear in any list that has reached me this year.

It must not be supposed that Poetaz Narcissi are solely of use for pots or bowls; they are good garden plants, and the bulbs

NARCISSUS KLONDYKE.

A showy Poetaz variety, with yellow perianth and deep golden crown or cup.

cost from 1s. 3d. to 21s. per dozen, the most expensive being Jaune à Merveille and Sunset, while Elvira is about the cheapest. Anyone proposing to plant these narcissi in some quantity should obtain the catalogues of the various bulb specialists (addresses will be found in the advertisement columns), and compare prices, because a certain variety or varieties may be found listed at a lower rate in one catalogue than in the others. As an example, one may find Klondyke priced variously at 2s. 3d., 3s., and 7s. 6d. per dozen, and as no one firm of repute seems to enjoy the monopoly of low prices throughout the section, readers should obtain catalogues as suggested, and spread their orders if they feel it is worth while to do so.

Three varieties I have found especially good for general purposes are Aspasia, Elvira, and Klondyke. The two former are white, the first with a golden cup, and the second with an orange-rimmed yellow cup; while Klondyke is soft yellow, with golden cup. This latter variety is figured in the present issue, and the illustration represents flowers finely exhibited in the spring by Mr. Christopher Bourne, of Simpson, Bletchley, and no head carried fewer than six blooms. Jaune à Merveille, illustrated in September last, is generally considered to be the finest yellow variety, and for pots and for exhibition it is most desirable, as the flowers are large and flat, and the golden crown is much deeper in hue than the soft primrose-yellow perianth. Sunset is another fine yellow, the crown being quite orange-tinted; this gives a well-formed, flattish flower of bold appearance, and is therefore a variety to grow by all who propose to exhibit flowers or bowls. Irene is soft yellow, with deep orange-gold centre, and grows quite tall; some will prefer it to Klondyke.

Alsace, with its pure white flowers and yellow cup, is not listed in all catalogues, but is a deserving variety, because under similar conditions it is a trifle earlier than the rest. Ideal is a tall-growing white variety, with a showy orange centre, and grows almost as strong as Elvira. Triumph is another with white broad perianth segments and a yellow centre, and is of comparatively dwarf habit. Orient is a grand white variety, tall growing, and with a very effective red-edged cup. There remains Lucia, a tall grower, with yellow perianth and golden centre; and where all are so good it is no easy task to make a small selection, especially as the section is yet a small one; but Aspasia, Elvira, Jaune à Merveille, and Klondyke will do very well to start with if it be necessary to severely limit the varieties grown.

To all who have not tried Poetaz Narcissi, let me say that the stronger growth and bolder flowers of this section place the varieties far ahead of the polyanthus or Tazetta forms, and one can make no mistake in cultivating them.

C. H. CURTIS.

Mildew on Vines. — Owing to a desire to practise economy as regards fuel, many cultivators of grapes stop all fires during the summer months. While the weather remains warm no harm will result, provided the ventilation of the houses be well attended to, but I think it is false economy to refrain from firing when bad spells of weather come, especially in the case of late varieties of grapes, notably Muscats. Frequently, owing to a low night temperature, and then a sudden rise from sun heat early in the morning, mildew attacks both berries and leaves, besides causing the berries of Madresfield Court to crack.—G. B.

SOME AUTUMN FLOWERS.

The autumn garden seems to have been enriched by the increase in the number of hardy plants at least as much as that of any other season, so much, indeed, that it is not an uncommon thing to find gardens brighter in September than at Midsummer. Sometimes the garden gradually acquires this character before its owner is aware of it, and sometimes it is the result of deliberate arrangement in order that there may be some weeks of display after the return from the summer holiday, instead of a considerable number of the garden occupants displaying themselves at their best when there is no one there to see them. Many late summer flowers last right through September in a favourable season, especially with a little attention in the matter of picking off the dead blossoms, though they do not, as a rule, have the freshness of the true autumn flowers, which do not begin to bloom much before the end of August, and often later. Many plants are never more beautiful than when they are just beginning to flower, for then we have no blossoms past their best, but the maximum number of unfolding flowers in all stages of development.

Early-flowering Chrysanthemums.

The first to be mentioned must be the queen of the autumn garden, the early-flowering chrysanthemum. Everyone grows these after a fashion, but few make them as effective as they should be. Strong healthy plants are a prime necessity, but they are not always to be had. When old plants survive the winter they should be broken up, and the most vigorous and best-rooted pieces of young growth replanted, taking any cuttings that may be wanted from the remainder. Of the multiplication of varieties there is no end, but for outdoor purposes the more recent introductions are by no means all improvements. The weakness of the flowering stems is a drawback of the Marie Masse type, though this has its compensations, for in wet weather the flowers hang their heads, and the water runs off them without doing much harm, while in the newer varieties, with strong upright stems, the open flowers have to stand the whole brunt of the wet, and a few days of wet weather often spoil them. This is the case with such varieties as Champ d'Or and Roi des Jaunes, which have displaced Horace Martin in some catalogues, though the latter variety will give points to several of the others during bad weather, and we generally have at least some bad weather, with heavy rains, at this season. For plantations in the garden it is doubtful if there are any to beat the deep yellow varieties. They show up better, and, possibly, suffer less from wet than any other colour. Slight disbudding is advisable for some of the early-flowering varieties even in the open ground. Two or three good blossoms on a spray are better than eight or ten more or less jammed together.

Michaelmas Daisies.

The Michaelmas daisies, in all their infinite variety, must receive full consideration. Remarkable improvements have been made with some kinds during the last ten or twenty years, but even to-day, with hundreds of varieties to choose from, a dozen that have been carefully selected will give one the best specimens of each type, while the old species, Aster acris, still remains as good as any for some purposes. They are well adapted for naturalising on banks or by woodland walks, and in the semi-wild parts of the garden fine effects may be produced with them. Some require to be arranged in masses, while others should be grown as specimen plants, though there are not very many of the latter class. Last autumn I had a large group of A. novi-belgi William Marshall, and the effect of the perfectly shaped deep mauve flowers against the background of their own dark green foliage was one of the finest of the year. As a contrast to this I had one small clump of about four stems of Hon. Edith Gibbs, which exceeded five feet in height, and was more in diameter, clothed from the ground upwards with its myriad blossoms. They may all be moved at any time late in the autumn or spring, but while the novi-belgi section should be moved every year, for the plants naturally break up into such conveniently rooted pieces that it can be done at any time from October to May with impunity, others of the non-spreading type, such as cordifolius, are best left for a couple of years undisturbed. Of the dwarf varieties everyone should grow Aster acris, and at least one variety of A. amellus, and of the taller sorts William Marshall, Hon. Edith Gibbs, Hon. Vicary Gibbs, and, to flower when all these are over, cordifolius Ideal, one of the best for cutting. These tall sorts are handsome in the bud stage, and after flowering also.

Miscellaneous.

The dahlia is so constantly changing—is it not well called Dahlia variabilis?—that the non-specialist scarcely knows where he is, and choosing varieties at shows often leads to disappointment, as so many make no display in the garden by reason of their shortness of flower stems, though things are improving in this respect. The annual aster is the flower of the autumn par excellence. We have, however, to wait a long time for it, and the plant does not last in full beauty very long when we have it. A place should be found for them where they will be sheltered from the early autumn gales, or the bed may be wrecked just as it is becoming beautiful. Fuchsias are essentially autumn flowers, rejoicing in the dewy mornings, and having a fresher appearance in early October than in July and August. The hardy bush fuchsias, which make such beautiful hedges and specimen plants in the west and south-west, and in some favourable positions elsewhere, can scarcely be recommended for cold inland districts.

A flower which always suggests autumn, though it often comes a little before it, is the torch lily. Unfortunately, it is not very hardy in cold situations and soils, but a little protection will carry it through most winters. It is not a subject for small gardens or borders, but should be grown where it is not out of proportion to the scale of its surroundings, for small plants with one or two spikes are not effective.

Of the autumn sunflowers the best are Miss Mellish and rigidus semi-plenus, which, when well grown, are very effective in lighting up the garden in succession from late August till mid-October. Another large-growing perennial is Solidago Golden Wings, which lasts in flower two or three weeks, and, as a well-grown specimen, with a spread of six or eight feet, is a beautiful object for two or three weeks before flowering. The Japanese anemone, perhaps of more refined beauty than any of our autumn flowers, has one great advantage possessed by few flowers of summer and autumn, and that is it does better in a damp and shady place than in full sun, and, therefore, can be put where few other things can.

A. C.

For your GARDEN

TWO BEAUTIFUL BORDER PLANTS

An ornament and an asset to any garden, large or small, equally for the owner of a small garden as for the owner of a large one. No experience is needed to enable all to enjoy the beauties of

KELWAY'S LOVELY PAEONIES & DELPHINIUMS

as they are exceptionally hardy and will flourish under almost any conditions. They provide splendid cutting flowers for decoration of every kind.

NOTES FROM KEW.

The middle of September is by no means the season at which the greenhouse is seen at its best, for many of the summer-flowering occupants of that structure are then on the wane, while the chrysanthemums, which make such a show later on, are not yet available. In spite of all this there is a goodly show of flowers at Kew, towards which begonias of various kinds contribute liberally. Tall specimens of Begonia coccinea and B. Luzerna are carrying their massive drooping clusters of bright-coloured blossoms, while of the true species may be mentioned B. Evansiana, B. Dregei, with its profusion of white flowers; B. Haageana, handsome both from a foliage and flowering point of view; with the pretty, slender-growing B. fuchsioides. Garden varieties that stand out prominently include among their number Bavaria, Saxony, Semperflorens Bonfire, Ingrami, and semperflorens gigantea.

Other flowers include zonal pelargoniums, streptocarpuses; Clerodendron fallax, cannas, and many of the usual occupants of the structure at this season. Bulbs consist of Lilium speciosum, represented by different varieties, Lilium Henryi, and some fine examples of Crinum Powelli, and its pure white variety alba. Tibouchina heteromalla is very striking just now, as also is a well-flowered batch of bright-coloured lantanas, whose value at this season for greenhouse decoration might be considered more than it is at present. Primula Kewensis and P. obconica are both flowering freely, while the orange-coloured berries of Nertera depressa form a very pleasing feature.

A striking effect is produced by a number of garden varieties of clematis in full flower. They are comparatively dwarf plants, trained to a single stem, and flowering freely on the upper part. Many of the finest garden forms are represented, and altogether they make a goodly show. The greenhouse also contains a great variety of climbing plants, among which some are just now in a particularly attractive condition.

Begonia Sanderæ.

Several examples of this showy begonia of garden origin are in flower in the greenhouse. It has an erect habit of growth, and bears a certain amount of affinity to B. Lynchiana, formerly known as B. Roezli. The flowers of B. Sanderæ, which are borne in good-sized clusters, are of a brilliant shade of orange-scarlet.

Nægelias.

Numerous varieties of these showy gesneraceous plants have for a long time been in flower in the cool portion of the T range, and, though some of them are past their best, sufficient yet remain to make a goodly show, which illustrates well the great variety that exists among these charming flowers. Though grown under the name of Nægelia at Kew, they are in many gardens referred to as the genus Gesnera.

Jasminum Maingayi.

Although seldom met with outside of Kew, this comparatively new jasmine from Penang is so attractive trained to the roof in the intermediate portion of the T range that it should ere long be more generally grown. It is of free growth, the foliage is of a rich green tint, and the pure white, starry flowers are borne in great profusion. Only in one nursery list have I met with this desirable species of jasmine.

Warm House Balsams.

These loom largely among the floral embellishments of the intermediate portion of the T range. Impatiens Hawkeri with magenta-violet flowers, whose susceptibility to mite has led to its being discarded in many gardens, is represented by a well-grown group of plants, all flowering freely. The typical Impatiens Holsti, too, with rich vermilion-coloured flowers, also makes a goodly show, though the individual blooms are smaller than those of the others. The large, flat flowers of a distinct orange-salmon shade form a very striking feature of I. Herzogi, one of the latest additions to this useful class of plants. The hybrid, Impatiens Kewensis, is also finely in flower, and a good deal of variability may be noted among the plants.

Ipomæa Leari.

In the same structure as the balsams a specimen of this Ceylon ipomæa is trained to the roof, and flowering with great freedom. It is of quick growth the slender, twining shoots being clothed with heart-shaped leaves, rather thin in texture, and somewhat liable to be attacked by red spider if the atmosphere is too dry. The large, fragile-looking flowers are of a charming shade of rather light blue with a lighter centre. This ipomæa is one of the shrubby species, and not of annual duration, as many of them are.

Hippeastrum reticulatum.

This, the oldest of all the hippeastrums, is in flower in the T range. Its strap-shaped leaves have an ivory-white midrib and it is in this respect alone readily distinguished from the other hippeastrums. The flower scape, which is not much over a foot in height, bears about half a dozen blossoms three inches or so in diameter, and of a soft lilac-pink tinge, with deeper-coloured veinings. This hippeastrum was introduced from Brazil as long ago as 1677. A second species, H. aulicum, with red flowers, is also in bloom.

Odontadenia speciosa.

This is a near relative of the Dipladenias; indeed, it used to be known as Dipladenia Harrisi. It is, however, far more vigorous than most of the dipladenias, and needs a large structure to enable it to flower well. In the Victoria Regia house it is just at home, for, with ample room to grow, and full exposure to the sun, it flowers freely. In colour the flowers are orange with, in some cases, a reddish suffusion. Though very fine when at its best, it is useless to attempt to flower this odontadenia in a small and shaded structure. Close by, a specimen of the delicate blue Thunbergia grandiflora is also blooming freely, thus showing that similar conditions suit it well.

Zephyranthes candida.

The band of this wind flower which has for some years edged the border outside of the orchid house is now in full bloom. It is so attractive when in this stage that its suitability for such a purpose is well shown. When thickly laden with blossoms the resemblance to an edging of white crocuses at a little distance is very marked. Close inspection, however, reveals a difference both in flowers and leaves, these last being quite rush-like. In some parts of the border a background of Gerbera Jamesoni in bloom serves to show off the white blossoms of the Zephyranthes to considerable advantage.

Kniphofias.

Close by the zephyranthes are some beds of kniphofia, and the flowers are very striking even at a considerable distance. Among the best at the present time (middle of September) are K. corallina, K. aloides Saundersi, K. aloides glaucescens, and the distinct K. Tysoni. In contrast to these large-growing kinds may be noted K. breviflora with quite small heads of the yellow flowers. K.

WIRED, ETC., FLOWERS.

Although the exigencies of transport of flowers for exhibition frequently demand artificial treatment in the way of support while in transit, or even during exhibition, there is no doubt that when new flowers are intended to be put forward for awards they should be entirely divested of any artificial aid whatever, either in the way of such support by wire or sticks, or by "dressing," i.e., special treatment and arrangement of their petals. It is, however, too frequently the case that, despite rules to the contrary, new, or presumed new, varieties are put before the judges for consideration, with the result that, being so treated, they are tacitly or openly considered as disqualified thereby. Such disqualification obviously is perfectly justifiable. Blooms with long, slender stems stiffened by wires may make a very brave show, while, under purely natural conditions, to which, as most of the purchasers, on the strength of given awards, would certainly subject them, they would be quite unfitted for garden culture owing to their lax habit. "Dressed" flowers, too, such as roses, may possibly give a quite false idea of beauty and good form, which they could never exhibit as garden plants, and so with many others. Some carnations, too, particularly of the Malmaison section, are prone to burst their calyces owing to the redundance of their petals, and it is clearly wrong to obtain, or attempt to obtain, an award when this serious fault is precluded by the artful aid of a slender rubber ring, removed, maybe, at the last moment, but the trace of which is quite perceptible, to the eye of the suspicious expert. Various other "dodges" might be cited in support of the moral—that exhibitors would be well advised to put forward their novelties on purely natural lines, and thus avoid the disappointment inevitable when the judges are properly qualified. C. T. D.

Cauliflowers.—At the present day the majority of growers chiefly depend on spring sowing for the earliest supplies. For my own part I consider it good practice to make two small sowings during the month of September, the first about the 10th and the other a fortnight later. Should mild weather prevail, the later sowing will provide the best plants to prick out on beds of soil in cold frames: the soil should be poor and light in character, an excess of moisture during the winter months is generally fatal. Two suitable varieties for this sowing are Walcheren and Magnum Bonum, the latter variety is usually very good with us about the end of June or early part of July.—W. MESSENGER.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

SEASONABLE NOTES.—Permanent shadings that have not been removed by the recent rains, should now be washed from the roof glass of all the warm divisions. Discretion must be used in working the roof blinds so as to afford the plants as much light as possible without scorching or disfiguring the foliage. It is always desirable to be on the safe side, and especially is this the case where permanent shading has been used beneath the blinds. In the cool divisions, where the plants have been repotted, great care is necessary, and even with plants that have not been repotted it is not desirable to have the foliage turning a russety-red colour. The effects of over-strong light on the foliage produces this effect, and such leaves quickly ripen and die, leaving more leafless pseudo-bulbs than are desirable for the appearance of the plant. It is some time before the plants complete their growth and produce their flower scapes, so there is ample time to mature the pseudo-bulbs.

DAMPING DOWN.—With the shortening days, and cool mornings and evenings, evaporation will not be so rapid, and consequently less damping will be necessary. When the outside conditions are cold in the mornings the damping should be delayed until the normal degree of temperature of the division has been reached. Damping in the afternoon should be done sufficiently early to permit excess of moisture to evaporate before the evening temperature is reached.

FIRING.—In the northern districts it will be found desirable, even on fine days, to start the fires early in the afternoon. This not only prevents accumulation of moisture in the atmosphere, but also permits the freer use of the ventilators. It is desirable to admit as much fresh air as possible at this season, and it is a good plan to open the roof ventilators the last thing at night, whenever the outside conditions permit.

DECIDUOUS DENDROBIUMS. — The different species and hybrids now completing their growth should have less root moisture. After growth is completed only sufficient water is necessary to keep the stems plump. Afford ample light, and ventilate freely whenever weather permits. It is desirable to keep the plants under close observation, as with a drier atmosphere insect pests, such as red spider and thrips, quickly make their appearance. It is advisable to syringe or spray the plants early on fine days. All plants of this section that have not completed their growths should be placed in the warmest and brightest place available, and given every encouragement to mature their pseudo-bulbs during the next few weeks while the weather is favourable.—H. J. CHAPMAN, Oakwood Gardens.

STOVE PLANTS.

ANTHURIUMS.—These plants will now require rather less water at the roots, and a rather drier atmosphere than when in full growth. A. Veitchi and A. Woroqueanum, having fully developed their fine leaves, care should be taken that in moving them or rearranging plants around them their foliage is not torn or damaged, for a slightly torn leaf or two will disfigure the best-grown specimen. They will require to be examined occasionally and sponged with care. If the compost has become at all loose, carefully make it firm, and at the same time some leaves may be staked out to give them more prominence and the plants a more shapely appearance. A. Andreanum, with careful attention will continue to produce its brightly-coloured spathes throughout the autumn and winter.

ACHIMENES.—When these have quite died down, and the tubers are ripened, the tops may be removed, and the tubers stored under the greenhouse stage or in any dry place where frost is excluded.

CALADIUMS.—The later batches are now becoming rather shabby in appearance, and should occupy a shelf in full light, with fair ventilation in nice weather. They will require only occasional waterings until when fully ripened they may be stored away for the winter in a dry position where a temperature of about 60 degrees is maintained.

MYRSIPHYLLUM ASPARAGOIDES (SMILAX).—As outdoor foliage becomes scarce there will be a greater demand for this and elegant leafage for the table and other decorative purposes. Every care should be taken that it is growing to its strings and not becoming entangled. Plants raised early in the year from seeds will be growing freely in their final quarters, and may now be assisted by occasional applications of soot water and weak liquid manure. To keep in the year from aphides the house in which it is growing may be fumigated occasionally.

ADIANTUMS.—These will now require a rather drier atmosphere, ventilating the house slightly upon all favourable occasions and utilising a little fire-heat in dull, cold weather. Carefully remove decaying fronds, and in rearranging give all possible room between the plants, so as to keep the fronds in good condition over as long a period as possible. Similar treatment will also benefit nephrolepis, the crested forms of which have become almost indispensable for decorative purposes.—H. PRIME, Hatfield House Gardens.

FRUITS UNDER GLASS.

ORCHARD HOUSES. — Trees of early varieties of peaches and nectarines from which the fruits were gathered in May and June should be examined, and, in the event of any of them requiring potting, no time should be lost, as the ripening leaves help to make new roots, and pots well filled with roots must be ensured to obtain the best results. The potting of fruit trees is now well understood, and I need not enter into details; but I must repeat how important it is to have good drainage, and to see that the soil is made thoroughly moist by watering before they are turned out of the pots. I prefer repotting the trees annually; young trees may be given pots a size larger than previously, but old trees which require reducing should be turned out and have a quantity of the inert soil picked out carefully with a pointed stick until the mass of roots resembles a mop of fibre. Shorten back the strong roots and repot, using clean pots of the same size as before. Use compost in a rather dry state, and spread the roots as much as possible by working the tree up and down a little before ramming the compost well down, finally finishing off with a broad-headed rammer, and leaving two or three inches room for water. September-potted trees require one good watering, after which light syringing should be given to keep the foliage fresh until the flower buds are matured.

PEARS, APPLES, PLUMS, AND CHERRIES.—Where these are grown as well as peaches and nectarines, the fruits will have been found most valuable this season, as outdoor supplies are limited, and all the above give excellent returns with careful attention. Such of these trees that require a shift into larger pots should be given one, but of two evils it is better to have medium-sized pots full of roots rather than large ones containing soil that is not fully occupied. Cherries especially swell up magnificent fruits when root-bound if properly top-dressed and fed throughout their season of activity. All stone fruits enjoy a calcareous loam, lime-rubble, wood-ashes, and sprinkling of bone-meal, which cannot easily be made too firm by ramming. Keep the roots moderately moist during the winter, as dryness at the roots after the leaves fall is one of the most common causes of bud-dropping when the trees are placed in gentle heat.—F. JORDAN, Warter Priory Gardens.

THE FLOWER GARDEN.

CALCEOLARIAS.—The beginning of the next month is a most suitable time to propagate calceolarias. Sturdy basal growths are to be preferred when selecting the cuttings, and these should be cut off immediately below a joint, have the bottom leaves taken off, and inserted in sandy soil in a cold frame from which it is possible to exclude frost. The frame should be kept close until the cuttings have become callused. Calceolaria amplexicaulis is a most desirable kind, and is annually gaining in popularity; it is particularly suitable for large beds, and for filling bare places in the herbaceous borders. It needs no further attention in its cultivation than that usually allotted to the dwarf, shrubby bedding varieties, beyond requiring more space in the frames at the time of transplanting in the spring, and to be allowed to grow naturally.

ANNUALS.—The practice of sowing annuals in the autumn is a speculative undertaking, as during the winter months the small seedlings are exposed to damage through inclement weather, or from the ravages of snails, etc.; but when they can be brought successfully through this ordeal many of them give better results than when sown in the spring, their habit being much more sturdy, and they flower over a longer season, all of which is an inducement to continue the system. Now is a good time for sowing, as it gives the seedlings a chance to make some headway before the winter. There are numerous annuals with a constitution equal to this treatment, and among them I may mention a few as being particularly effective, i.e., godetias, clarkias, nemophila, limnanthes, silenes, cornflowers, scabious, viscarias, larkspurs, etc.

THE ROCK GARDEN.—The present time is usually a busy one in this department. In any work of construction the fact that rock plants in general require a soil in which they can root deeply must not be lost sight of when placing the pieces of rock in position. A rockery may have the appearance of being naturally constructed, and yet prove very unsatisfactory as a home for a variety of rock plants, because where deep pockets should exist between the boulders, into which the occupants can thrust their roots deeply enough to withstand a drought, they consist of a shallow covering of soil over hidden stones; and this condition is not an uncommon one, especially on rockeries of small dimensions where a number of large and somewhat flat-topped stones are used. Autumn planting of all but the most delicate varieties of rock plants is to be recommended, as it has a decided advantage over such work carried out in the spring; the plants become well established, and are in a better position to withstand the effects of cold, drying winds usually so prevalent in March and April, therefore every effort should be made to complete as much of this work as possible during the month of October.

AUBRIETIAS.—These figure largely in all rock gardens, and, as the named varieties do not come true from seed, the stocks are kept going by means of cuttings, which, if inserted at this time of the year, root very freely, and soon grow into nice plants. Attempts to root aubrietias through the summer months prove very tedious and uncertain, as they appear to lose all vitality during hot weather.—T. B. FIELD, Wych Cross Place Gardens.

THE NATIONAL CHRYSANTHEMUM SOCIETY'S
EXHIBITION OF EARLY-FLOWERING

CHRYSANTHEMUMS

Will be held at the

CRYSTAL PALACE,

On OCTOBER 1st and 2nd, 1913.

Write for Schedule (post free) to the Secretary,
Mr. RICHARD A. WITTY,
72, Savernake Road, Gospel Oak, S.W.

ADMISSION TO PALACE (including Show), 1s.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

There was a "full house" at Vincent Square on Tuesday, September 23, both as regards exhibits and visitors, although the latter thinned out very early in the afternoon, and by five o'clock few but exhibitors remained. Besides exhibits coming before the several committees, there was a fine dahlia competition for the Cory Cup, and the Society's Vegetable Show. Novelties were fairly numerous and interesting. Orchids were very bright, and with dahlias, Michaelmas daisies, vegetables, and fruits, made up a capital display.

Practically all the regular habitués were back from holiday, and everyone was glad to see Mr. John Heal, V.M.H., again, now fairly well recovered from the severe accident he sustained some months ago.

HARDY FLOWERS.

Messrs. W. Cutbush and Son, Highgate, displayed pentstemons in vases, and showed such varieties as Mrs. Leonard Cutbush, scarlet; Mauve Queen, Mrs. Baird, Miss Baird, pink; and Pink Pearl. Mr. James Box, Lindfield, put up handsome spikes of Lilium nepalense and L. sulphureum, both lovely lilies, and in this case the spikes were cut from the open; Cimicifuga simplex was also very beautiful, and Crinum Powelli was capitally shown. Mr. Ernest Ballard, The Court, Colwall, whose work among Michaelmas daisies is well known to our readers, put up a large exhibit of his favourites, including the double sorts Cloudy Blue, Nancy Ballard, and Beauty of Colwall, and the singles Jupiter, new, large, pale lilac-blue; Neptune, blush. Michaelmas daisies from the Wargrave Plant Farm, Lim., The Arcade, Liverpool Street, made a pretty display; the smaller-flowered sorts, such as ericoides, Bianca, Golden Spray, Symphony, Virgin Queen, Ophir, and Perfection, were very graceful.

Messrs. W. Wells and Co., Merstham, again displayed phloxes, and set up Le Mahdi, Eclaireur, Salome, Mons. Kind, the soft lilac Mdme. Paul Dubrie, the large white, violet-budded Distinctive, and the new Emile Michel, old rose, with violet-shaded eye. Rev. J. H. Pemberton, Haverıng, again submitted his roses Danaë and Moonlight, and gained an A.M. for the latter. Messrs. Herbert Chapman, Lim., Rye, also again showed their fine salmon-scarlet Nerine Rotherside, very bright.

DAHLIAS.

A number of new pæony-flowered dahlias, all remarkable for their stout, erect stems, carrying the big, glorious flowers in position and holding them up finely. These were exhibited by Messrs. Warnaar and Co., Sassenheim, Holland, for whom Messrs. Whitelegg and Page, Chislehurst, are the English agents. A few of the finest were Duchess of Brunswick (A.M.), orange-red or orange-salmon; Mrs. Vaughan (A.M.), soft yellow, and suggestive of cactus dahlia form; Chatenay, lovely salmon-pink; Leo XIII., golden-yellow; H. J. Lorinck, pink and lilac-purple; and Zeppelin, violet, tinted lilac.

A gorgeous exhibit of dahlias, composed entirely of collarette varieties, set up in vases and pyramids, was from Messrs. Dobbie and Co., Edinburgh. The most brilliant varieties were Madam Gygax, Holyrood, Henri Farman, Prince of Orange, Queen Anne, Goldstein, Queen Bess, Princess Louise, Diadem, and Frogmore; in these varieties we have the most brilliant shades of yellow, orange, scarlet, and ruby-crimson. Mr. J. B. Riding submitted a very bright collection of pæony-flowered, decorative, and collarette dahlias, associated with suitable foliage.

Among new dahlias we noted Rupert (A.M.), a flame-coloured golden based flower of garden cactus type, on stiff stems; Edith Carter, a distinct, erect cactus variety, with golden florets, the upper halves deep pink. These were shown by Mr. H. Shoesmith, Woking. Messrs. Stredwick and Son, Silverhall Park, St. Leonards, presented a number of new dahlias, and gained an A.M. for Dorothy Hawes, a cactus variety previously described in these columns. Messrs. Burrell and Co., Cambridge, submitted new cactus dahlias, and secured an A.M. for Homere, a deep crimson-maroon cactus variety of fine form.

OTHER FLOWERS.

Messrs. Robert Veitch and Sons, Exeter, brought up Nerine Bowdeni, some of the spikes from outdoor-grown plants; N. Bowdeni pallida, Calceolaria Veitchi, and the very curious red and yellow, long-tubed Lobelia Cavanillesi, quite hardy at Exeter. Gloriosa Carsoni has yellow petals, the upper half of each petal being dark chocolate-purple, except for yellow margin; this was shown by Messrs. Ridley and Co., Wellington, Somerset. Market Favourite pink, a late-flowering sort, white, laced with pale crimson, was sent by Messrs. Ladhams, Lim., Shirley, Southampton.

Messrs. Allwood Bros., Hayward's Heath, presented a collection of perpetual carnations, and set up the new Yellow Stone, a promising soft yellow variety, shown for the first time in this country; and Fairmount (A.M.), a large, full flower of soft heliotrope shade, with very faint fragrance. The perpetual carnations from Messrs. Stuart Low and Co., Enfield, included Satin Robe, the new and well-named Salmon King (A.M.), and the lovely Empire Day.

ORCHIDS.

At the meeting of the Orchid Committee the Chairman paid a tribute to the memory of the late Mr. J. S. Moss, who for many years was a member of the committee, and whose recent decease was so deeply deplored by orchid-lovers.

A charming group of orchids from H. S. Goodson, Esq. (gardener, Mr. J. Day), Fairlawn, Putney, was notable for its large series of autumn-flowering lælio-cattleyas, L.-c. callistoglossa and L.-c. Bletchleyensis standing out conspicuously; a few odontoglossums added elegance to brilliant colouring. Mr. Black, gardener to R. G. Thwaites, Esq., Streatham, made a good show with Cattleya Iris and C. adula. Mr. C. Bristow, gardener to Mrs. Temple, Leyswood, Groomsbridge, showed a Cypripedium Ashburtonæ, a very old hybrid, with two dozen spikes, most of them carrying a pair of flowers.

A very pretty group from Messrs. Charlesworth and Co., Haywards Heath, was rendered very graceful by the long sprays of Oncidium incurvum, Odontoglossum crispum xanthotes, Vanda cærulea, and the brilliant Epidendrum vitellinum majus. In the foreground were capital examples of Lælio-cattleya callistoglossa (one with seven lovely blooms). Dendrobium Dearei, the white Cattleya Alamanda, and the curious large-lipped, white and green Angræcum infundibulum. In the group from Messrs. Hassall and Co., Southgate, Cattleya aurea, C. Hardyana, C. adula, C. minvica, and other autumn bloomers were well shown.

Vanda cærulea was the centre of attraction in the orchid group arranged by Messrs. Sander and Sons, St. Albans, but with this blue-flowered species were miltonias, a series of autumn-flowering lælio-cattleyas, Cypripedium Pyrrha, the purple Odontonia Machabiana, and the quaint Saccolabium acutifolium. Messrs. J. Cypher and Sons, Cheltenham, presented the wonderfully fringed Habenaria Suzannæ, the rare Bulbophyllum grandiflorum, Cypripedium triumphans, C. Gaston Bulteel, and the handsome Odontoglossum grande.

Messrs. Armstrong and Brown, Tunbridge Wells, had Cattleya Iris in good form, C. Armstrongæ, C. Atalanta, and the fine Lælio-cattleya George Woodhams, recently figured in our columns, but, perhaps, the loveliest orchid in their group was Oncidium corynophorum with its long spike, nearly four feet long, carrying beautiful mauve, purple, and white flowers. The new bright red Odontioda Joan var. Rawdonensis, was sent by Messrs. Mansell and Hatcher, Leeds, and Mr. E. H. Davidson, Orchid Dene, Twyford, put up Cattleya Cybele Davidson's var. (A.M.), blush and purple; Odontoglossum Woodroffæ, and O. Twyford Gem, each O. Rossi hybrids.

FRUITS AND VEGETABLES.

An especially interesting feature of the show was a collection of Aubergines or Egg Plants, exhibited by Mr. G. Cradduck, gardener to Colonel the Right Hon. Mark Lockwood, M.P., Bishop's Hall, Romford. Colonel Lockwood has been particularly anxious to show the capabilities and varieties of aubergines, as grown under glass in this country, and for several years Mr. Cradduck has grown a considerable collection. There were four dozen plants, all remarkably well fruited, and representing fourteen varieties, some round, some oval, and some quite elongated, almost like small German sausages. In colour there was some variation from white to darkest purple, while a few very ripe fruits were yellow. Mr. Cradduck tells us that Early Long Purple, Perfection, and Tokio are the best varieties for cooking. Others very attractive were Long White Giant, Black, Round White, Purple Pekin, very large and roundish Round Purple, Long White China, Striped, and Scarlet. The plants were raised from seeds sown in March last. The group was a centre of interest, and Colonel Lockwood was heartily congratulated upon his success.

Messrs. Sutton and Sons, Reading, put up a superb display of vegetables, and showed that fine selections and varieties, finely grown, may be arranged to produce a most attractive exhibit. In the matter of colour such an exhibit lacks nothing, while as a demonstration of high culture, and the variety to be found in cultivated vegetables, it ranked high in educational value. We have so often referred to the Sutton specialities that there is no need to go over the ground again, but we would point out that among uncommon vegetables the Reading firm on this occasion exhibited custard marrows, Seakale beet, New Zealand spinach, aubergines in various shapes and colours, maize, capsicums, kohl rabi, yellow waxpod beans, and yellow turnips. Onions, celery, potatoes, leeks, and all the rest of the hundred and seventy dishes were all up to Sutton standard, and one cannot say more than that.

Mr. Thos. Smith, gardener to the Marquis of Ripon, Coombe Court, Kingston Hill, submitted about sixty dishes and nearly as many varieties of apples of fair quality, but good, when it is remembered that they were grown on thin, light soil.

Mr. D. Vigo, Thaxted, showed vegetables, apples, and melons, but made no attempt at good arrangement. Mr. Wilkins, gardener to J. H. Porter, Esq., Malden, Surrey, showed very fine dishes of The Queen, Ribston Pippin, Warner's King, Peasgood's Nonsuch, Emperor Alexandra, Cellini, New Hawthornden, and Cox's Pomona apples—a

bronze medal seemed scarcely an adequate award for fruits of such fine colour and quality.

Premier onion, of fine form and size, was finely shown by Messrs. Dickson and Robinson, Manchester, who staged about sixty weighty and clean bulbs.

AWARDS OF MERIT.

No First-class Certificate was awarded on this date.

Award of Merit.—To Carnation Fairmount, from Messrs. Allwood Brothers, Wivelsfield, Haywards Heath; to Aster Mrs. Frank Lean, from Mr. H. J. Jones, Lewisham; to Aster Beauty of Ronsdorf, from Messrs. Thos. S. Ware, Feltham; to Rose Moonlight, from Rev. J. H. Pemberton, Havering, Romford; to Berberis aggregata, from Hon. Vicary Gibbs (gardener, Mr. E. Beckett), Aldenham House, Elstree; to Primula vincæflora, from Prof. I. Bayley Balfour, Edinburgh Botanic Gardens, to Chrysanthemum Olive, from Messrs. W. Wells and Co., Merstham; to Carnation Salmon King, from Messrs. Stuart Low and Co., Enfield; to Lælio-cattleya Armada, from Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Gloucester; to Cattleya Cybele, Davidson's var., from Mr. E. H. Davidson, Twyford, Berks; to pæony dahlias Baroness von Brunswick and Mrs. J. C. Vaughan, from Messrs. Warnaar and Co., Sassenheim, Holland; to dahlia Homere, from Messrs. Burrell and Co., Cambridge; to dahlia Dorothy Hawes, from Messrs. J. Stredwick and Son, St. Leonards; to dahlia Rupert, from Mr. H. Shoesmith, Woking; to dahlia Reginald Cory, from Messrs. J. Cheal and Sons, Crawley; and to dahlia Ruby, from Messrs. J. Cheal and Sons. The awards to dahlias were made by a joint committee of the R.H.S. Floral Committee and the National Dahlia Society.

MEDALS.

Gold.—Messrs. Sutton and Sons, Reading, for vegetables.

Silver Flora.—To Messrs. Dobbie and Co., Edinburgh, for collarette dahlias; Messrs. Charlesworth and Co., Haywards Heath, for orchids; to Messrs. Armstrong and Brown, Tunbridge Wells, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to H. S. Goodson, Esq., Putney, for orchids.

Silver Knightian.—To Messrs. Dickson and Robinson, Manchester, for onions; to Mr. Cradduck, gardener to Col. Lockwood, M.P., Bishop's Hall, Romford (with Cultural Commendation), for collection of aubergines.

Silver Banksian.—To the Church Army, Westminster, for vegetables; to Mr. T. Smith, gardener to the Marquis of Ripon, Coombe Court, Kingston, for apples; to Messrs. Hassall and Co., Southgate, for orchids; to Messrs. J. Cypher and Sons, Cheltenham, for orchids; to R. G. Thwaites, Esq., Streatham, for orchids; to Mr. E. Ballard, Colwall, for perennial asters; to Messrs. W. Wells and Co., Merstham, for phloxes and chrysanthemums.

Bronze Flora.—To Messrs. Stuart Low and Co., Enfield, for carnations; to Mr. J. B. Riding, Chingford, for dahlias; to Mr. W. Treseder, Cardiff, for dahlia bouquets; to Wargrave Plant Farm, Lim., The Arcade, Liverpool Street, E.C., for Michaelmas daisies; to Mr. Jas. Box, Lindfield, for liliums, etc.

Bronze Knightian.—To J. H. Porter, Esq., Malden, Surrey, for apples.

DAHLIA COMPETITION.

The competition for the Cory Silver Cup, presented by Reginald Cory, Esq., Duffryn, Cardiff, was held on this occasion, and the judges were a committee composed of members of the R.H.S. Floral Committee and the National Dahlia Society.

The cup, valued at 75 guineas, was worth showing for, and brought no fewer than eleven entries. The specification read: "A group of decorative garden dahlias of all or any sections; 25ft. run of 3ft. tabling, not to be built up more than 8ft. in height from the ground level."

The judges had no light task, and eventually they awarded the cup for the ensuing year to Messrs. Carter Page and Co., London Wall, whose bold and brilliant exhibit of single, collarette, pompon, cactus, pæony-flowered, and decorative was very attractive. The firm made no special effort to secure an imposing or startling effect, but massed their flowers in stands and vases, and had just sufficient light colouring to emphasise the gorgeous hues. Such cactus varieties as Ames Perry, Mrs. D. Fleming, Arthur Pickard, Sweet Briar, and Johannesburg were capital, while Bayard as a single pæony-flowered sort, and Delice as a decorative, were very striking, and Souv. de Chebanne, Diadem, Frogmore, and Princess Louise were the most notable collarette varieties.

Messrs. J. Cheal and Sons, Crawley, were placed second, and were awarded a Silver-gilt Flora Medal for effective groupings of Loveliness, Mrs. F. Paton, Mrs. C. Foster, Princess Juliana, Lustre, Mrs. Greville, and other good garden varieties, as well as representatives of all sections of dahlias; this was a very bright display that followed closely upon the first-prize group.

Other competitors were Messrs. Keynes, Williams, and Co., Salisbury, who put up some very handsome stands of cactus and decorative varieties in association with coloured foliage and grasses. Mr. Charles Turner, Slough, used the large, white pæony-flowered variety Aphrodite, as a fine centre group to collarette, giant decorative, and pompon sorts in great variety. Messrs. Thos. S. Ware, Lim., Feltham, depended upon well-arranged stands of collarette and Parisian dahlias for their principal effect. Mr. J. T. West, Brentwood, showed Brentwood Yellow, Futurity, Geisha, and Mabel, all splendid varieties in fine form (Silver Banksian Medal).

Messrs. Hobbies, Lim., Dereham, gained a Silver-gilt Banksian Medal for a very effective group that was a trifle crowded, if any fault could be found; pæony-flowered varieties were placed at the back, then came cactus sorts, with collarette varieties rising from singles, pompons, etc., in the foreground. Messrs. M. V. Seale, Sevenoaks, put up very large stands of good cactus dahlias as a background to rather low vases of pompon, pompon cactus, and collarette varieties, shown just as cut.

Messrs. Wm. Treseder, Lim., Cardiff, had a very lightly-arranged display, and their central display of show dahlias was a capital idea. Mr. J. Emberson, Walthamstow, had a corner exhibit, and presented cactus, pæony-flowered, and collarette dahlias in fine form, and staged them most effectively.

AMATEURS.

In the amateurs' class the Rev. Arthur Bridge (gardener, Mr. C. Daisley), Worth Rectory, Sussex, won the silver cup offered for a collection of decorative garden dahlias, displayed on a space 12ft. by 3ft.; this competitor had a fine background of cactus dahlias arranged with foliage and grasses, and did well with such cactus varieties as Snowden, Mary Pornier, Mrs. Lonsdale, Sweet Briar, and Arthur Pickard, and used pompons, single, and collarette varieties in the foreground. Sir Randolf Baker, Bart. (gardener, Mr. A. E. Usher), Ranston, Blandford, was awarded a Silver Banksian Medal for handsome groupings of cactus and collarettes, with a few pæony-flowered varieties in rather low vases; a similar award fell to Mr. J. S. Kelly, gardener to the Duchess of Albany, Claremont, Esher, for an exhibit in which the green foliage of dahlias seemed a little too obtrusive, but the stems and flowers were all staged as cut, without any dressing or trimming.

VEGETABLE SHOW.

There was a fair amount of competition for the prizes offered for vegetables at the Royal Horticultural Society's Exhibition on September 23. The quality throughout was of a very high order, and great taste was shown in the display of collections. Notwithstanding the note placed on the exhibits in Class 2 by the council, no one seemed able to fully understand why the collections were disqualified, seeing that similar exhibits in a similar class have in previous years been admitted and granted prizes according to merit. If a different standard of judging was to be employed on this occasion, as it evidently was, it seems only just that due notice should have been given.

There were five entries for the premier collection of twelve kinds, distinct, all of which were splendidly grown. The first prize was awarded Mr. E. Beckett, gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, who staged splendid examples of celery Superb Pink, cauliflower Early Giant, leek Prizetaker, superb examples of Ailsa Craig onions, Tender and True parsnips, with Superlative potatoes. The entire exhibit was well displayed in a bed of parsley. The second prize was awarded to the redoubtable amateur exhibitor Mr. Thos. Jones, Ruabon, who had fine, well-ripened bulbs of onion Ailsa Craig, parsnip Marrowfat, runner bean Exhibition, leek Colossal, and British Queen potatoes; while the third prize was awarded to Mr. F. J. Barrett, Overton, Ellesmere, for a very creditable exhibit; Mr. H. Keep, Aldermaston, Reading, was third.

There were two entrants for nine distinct kinds, the object of the class being to illustrate vegetables in daily use, and possess the qualities most valued by cooks for table use. But, strange to relate, the judges did not regard splendid examples of vegetables suitable for the cooks, so both Mr. E. R. Janes, gardener to Lord North, Wroxton Abbey, and Mr. G. Ellwood, gardener to W. H. Myers, Esq., Bishop's Waltham, had to be content with a typewritten explanation of their failure to comply with the judges' ideas. The type-written notice on each of the exhibits read as follows. "The judges consider that the vegetables shown in class 2 do not strictly comply with the conditions set forth in the schedule for this particular class. The magnificence of the products from the point of view of the art of cultivation is unquestioned, but the items do not illustrate or possess the essential qualities looked for by the cook, with the exception of the cauliflower and tomato." These have taken prizes in previous years under similar circumstances.

The competition for six kinds, distinct, was most keen, there being five entrants. The first prize was awarded Mr. H. Smith, gardener to Mr. Brodie Henderson, Little Berkhampstead, who staged Giant Pink celery, Mont Blanc cauliflowers, Duke of York tomatoes, and the Gladstone pea in fine condition. Mr. J. Taylor, gardener to Mr. F. Bibby, Hardwicke Grange, Shrewsbury, was second; and Mr. T. Avery, gardener to the Right Hon. T. F. Halsey, Goddenden Place, Hemel Hempstead, a good third.

For a collection of twelve varieties of potatoes there were but two entries. Mr. A. Basile, gardener to Rev. T. McMurdie, Woburn Park, Weybridge, was the winner with a fine level collection, which, however, only contained one coloured variety. The best dishes were Conquest, Yeoman, Duchess of Cornwall, Mr. Bresee, New Chieftain, and Goldfinder. Mr. A. G. Gentle, gardener to Mrs. Denison, Berkhampstead, was a capital second, but lacking a little in finish: the best dishes were The Factor, Windsor Castle, King Edward, and Long Keeper. For six varieties, distinct, Mr. G. Thorn, Sprotlands, Ashford, Kent, was well ahead with six fine dishes of Empress, Purple Eyes, King George V., Chapman, and The Factor. Mr. F. L. Pike, gardener to Mr. H. W. Henderson, Serge Hill, King's Langley, was second, and Mr. J. Taylor brought up the rear with larger tubers, though they were somewhat green through exposure.

For six varieties of onions, distinct, there were four contestants, the first prize being awarded to Mr. H. Wheeler, gardener to Mrs. Jenner, Wenvoe Castle, Cardiff, who had

splendid examples of Ailsa Craig, Magnum Bonum, Excelsior, Golden Ball, Sutton's A1, and Premier. Mr. E. Beckett secured second prize with fine examples of Ailsa Craig, Excelsior, and Anglo-Spanish; while Mr. Ellwood was third.

There were only two entrants for nine kinds of salads, Mr. E. Beckett leading off with a most tempting exhibit which included lettuces, endive, tomatoes, radishes, cucumbers, beet, and cress; while the second prize fell to Mr. Thos. Jones for a worthy exhibit; while for six kinds Mr. G. Ellwood won first prize, having some fine tomatoes, lettuces, and endive, Messrs. H. Smith and E. R. Janes winning the other prizes in the order named.

For six kinds of vegetables of the minor order, Mr. E. Beckett secured the premier award, having good dishes of aubergines, celeriac, kohl rabi, salsafy, yellow capsicums, and scorzonera; Mr. E. R. Janes was second with some good red capsicums, kohl rabi, fine aubergines, and Chinese artichokes; while Mr. G. Ellwood was placed third.

The scarlet runner beans were excellent in such a season, the first prize going to Mr. H. Keep, who staged New Exhibition; Mr. H. Smith followed with typical examples of Scarlet Emperor; while Mr. G. Ellwood brought up the rear with Prizewinner. The prizes for climbing kidney beans were hotly contested, Mr. J. J. Staward, St. Fort, Newport, Fife, leading, followed by Messrs. G. Ellwood and E. Beckett in the order named. For dwarf kidney beans there were eleven entries, Mr. H. Smith being first with a splendid sample of Magpie; Messrs. T. Jones and W. West, gardener to Mr. Knox, Holt Hatch, Alton, taking the other prizes respectively. There was a capital entry for beet, most of the examples being well selected. Mr. F. L. Pike was first with Carter's Black; Mr. E. R. Janes being second with Sutton's Black; Mr. E. Beckett was third.

Messrs. G. Ellwood, F. J. Barrett, and F. L. Pike staged the best Brussels sprouts, and the prizes were allotted in the same order. The competition for three heads of sprouts only brought out two exhibitors, Mr. E. Beckett winning first, followed by Mr. F. J. Barrett. Cabbages did not produce a very keen display, Mr. E. Beckett having the best of six competitors. Mr. A. Wilkinson was first for three heads of savoys, staging Perfection. Cauliflowers were not great by any means, and Mr. E. Beckett was the fortunate winner; while Mr. A. Basile secured the first prize for celeriac.

Out of six entries for white celery, Mr. E. Beckett won with fine examples of Solid White, winning the first for red celery also. Cucumbers were not a very strong class, Mr. T. Avery winning with a nice brace of Telegraph. The exhibit of leeks attracted much attention, Mr. G. Ellwood taking the first prize with Sutton's Prizetaker, really fine examples; Mr. E. Beckett was second. Mr. E. Beckett won first prize with vegetable marrows.

Mr. H. Wheeler led off for six onions, having splendidly developed bulbs of Premier; Mr. H. E. Wallis was second. Mr. H. Wheeler again led off for six flat bulbs, staging some fine bulbs of A1. Mr. E. R. Janes won first prize for parsnips from nine entrants, staging Tender and True in perfect condition. Mr. E. Beckett secured the first prize for long carrots, staging new Red Intermediate; while Mr. J. J. Barrett was first for a dish of short varieties, staging Standard. In the class for peas, Mr. E. Beckett won well with the Gladstone; while Mr. T. Avery was first with White Stone Model turnips; in the other classes Messrs. Beckett and H. Wheeler were the first prize winners. In the single dish classes for potatoes the chief prize winners were Messrs. W. West, G. Thorn, and J. E. Shirley.

The tomatoes were excellent in quality, the first prize being awarded to Mr. H. C. Gardner, who staged Duke of York; while the same exhibitor was successful in the class for yellow varieties. The ornamental tomatoes did not produce anything remarkable, Mr. J. Taylor being awarded first prize with very large bunches of Wonder of Italy; while for any other vegetable not named in the schedule Mr. E. Beckett won first prize with Globe artichokes; Mr. A. Basile followed with fine red cabbages; while Mr. P. B. Awcock was third with a dish of salsafy.

Mr. G. Ellwood won the silver challenge cup for the highest points in the vegetable show.

National Chrysanthemum Society.

The Floral Committee had a small amount of work to do on September 22, but Messrs. W. Wells and Co., Merstham, saved the situation by staging about a dozen good bunches of showy flowers of early varieties, notably Olive, chestnut red; Susie, salmon-buff; Golden Firebrand, a sport from Firebrand; Wopsie, an orange and yellow single; Popsie, single white; and Annie, a light orange-yellow single. Messrs. W. Wells and Co. were accorded a vote of thanks for their interesting exhibit.

There was a goodly attendance at the meeting of the General Committee at Carr's Restaurant during the evening, and it was particularly pleasing to find twenty-five nominations for membership, including a number of Japanese gentlemen.

On Monday evening last the Executive Committee of this society held a meeting at Carr's Restaurant, when Mr. T. Bevan took the chair. The Bradford and District Chrysanthemum Society was admitted into affiliation. The Secretary reported on the annual outing, which took place on July 21 last, to Friar Park, the residence of Sir Frank Crisp, Bart. The day was fine, and 140 members and friends attended. Tea was provided by Sir Frank, and the whole undertaking was successful and greatly enjoyed. On November 27 Sir Albert Rollit has promised to take the chair at the annual dinner, which will be held at the Holborn Restaurant.

The Conference is fixed for December 10, the papers being as follows: "The Evolution and Development of the Outdoor Chrysanthemum," by Mr. Norman Davis; "Chrysanthemums for Outdoor Decoration," by Mr. Bevan. On the table were some fine examples of Mr. Bevan's cultural skill in the outdoor culture of these flowers, which were much admired.

In connection with the appointment of judges for the October and November shows it was resolved that the money prizes awarded should be paid immediately after each show.

Mr. Harman Payne gave some details concerning the Ghent Chrysanthemum Show and Congress to be held from the 25th to the 28th prox., and Mr. Bevan reported on his visit to the International Horticultural Congress held there last month.

Twenty-five new Fellows and members were added to the roll.

North of Scotland Horticultural and Arboricultural Association.

The annual meeting of the members of this association was held in the Botanical Classroom, Aberdeen University, and was largely attended. Mr. W. Lockhart, president, was in the chair. The Secretary, Mr. William Reid, submitted his annual report, which was considered very satisfactory. Mr. W. Wyllie, treasurer, submitted the annual balance-sheet, which was also regarded as very favourable. Both reports were unanimously adopted. The election of officials for the coming year was then proceeded with, and the following appointments made: President, Mr. Lockhart; vice-president, Mr. A. Robson; secretary, Mr. William Reid; and treasurer, Mr. W. Wyllie. The new members added to the committee were: Messrs. Henderson, J. M'Donald, W. Cumming, Tocher, and Ironside. It was agreed after a vote to affiliate with the Royal Horticultural Society, London.

Dumfries and Galloway Gardeners' Association.

This association, established in the beginning of 1913, held its annual business meeting in St. George's Hall, Dumfries, the other day. In the absence of the retiring president, Mr. S. Arnott, Sunnymead, the chair was occupied by Mr. William Hutchinson, Terregles Gardens, Dumfries, vice-president. The report of the past session's work was of a satisfactory character, and the prospects of the association are highly promising. On the motion of the chairman, Mr. S. Arnott was unanimously reappointed president. Mr. W. Hutchinson was re-elected vice-president, with Mr. David Hunter, of Messrs. Barr and Hunter, nurserymen, Dumfries, as honorary secretary and treasurer. Arrangements were made for the coming session, these including meetings on the first Saturday of each month, with special meetings at intervals. It was agreed to begin a collecting box for the Royal Gardeners' Orphan Fund.

Broughty Ferry Horticultural Association.

The ordinary monthly meetings of this association were resumed on the 16th inst. The President, Mr. James Bethel, presided over a good attendance. The lecturer was Mr. Wm. Grant, Fernhall Gardens, who had for his subject "Impressions of the International Horticultural Exhibition, Chelsea, 1912."

As the lecture was beautifully illustrated by upward of seventy lantern slides, it served to refresh the memories of those who had visited the exhibition, and proved a source of considerable interest and pleasure to those less fortunate.

On the motion of the President, the lecturer received quite an ovation for his interesting and instructive address. The monthly prize was awarded to Mr. David Keillor, Seabourne Gardens, for a stand of twenty-four cactus dahlia blooms, while the president exhibited James Grieve apples.

OBITUARY.

MR. J. S. MOSS.

Mr. John Snow Moss, of Wintershill, Bishop's Waltham, died at his residence on September 11. Mr. Moss, who was 54 years of age, was a well-known amateur horticulturist, and devoted considerable attention to orchid culture, and especially to raising hybrid odontoglossums and odontiodas. For many years he occupied a seat on the R.H.S. Orchid Committee, and he was a judge at the recent Ghent Horticultural Exhibition. Mr. Moss had recently paid a visit to the Continent, and was taken ill on his return home, death being caused by an apoplectic seizure.

MR. A. H. KENT, B.A.

At the advanced age of 85 years there passed away on September 12, after a long illness, one of the quietest of workers in horticulture—Mr. Adolphus H. Kent. Mr. Kent will be well known to many who have served at the Veitchian Nurseries at Chelsea, or at Kew, for he was an excellent botanist, and one of the gentlest and kindliest of men, always willing to give any information he possessed to an enquirer. He was severely handicapped by deafness, and this led him to relinquish his duties as a schoolmaster, and become private secretary to Mr. (now Sir) Harry J. Veitch. Mr. Kent was mainly responsible for "A Manual of Coniferæ," and rendered considerable assistance in the production of "A Manual of Orchidaceous Plants." Mr. Kent was born at Bletchingley, and obtained his B.A., London, in 1870. He was an associate of the Linnean Society, and in his earlier years was a musician of no mean order.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of THE GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of THE GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in THE GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

DISEASED STRAWBERRY LEAVES.—F. D., Taunton: For some time past my strawberries have been infested with a disease which makes itself evident in the form of blackish spots upon the foliage. There does not appear to be any marked reduction in the vigour of the plants as a result of this infestation, but I feel sure it must have a weakening influence. I enclose a few spotted leaves, and seek your advice concerning the trouble.—The disease is the strawberry leaf spot (Sphærella fragariæ), and one that is becoming more common in this country. In some parts of the United States it is a very troublesome pest. The disease so weakens the constitution of the plant that after a very bad attack the fruit crop may be a failure in the succeeding year. We wish you had written us before, as one of the best means of curing the trouble is to mow the leaves from the bed as soon as the fruits have been gathered, add some dry litter when the leaves are somewhat dry, and set fire to the whole. This may seem very drastic treatment, but it is a method that has been adopted with considerable success, and it is followed by a vigorous crop of healthy foliage. It is rather late to adopt such a method, but it is worth the risk; failing this, the best that can be done is to remove old infested foliage, runners, and weeds, and spray with Bordeaux mixture. In the spring, as new leaves appear, spray with weak Bordeaux mixture at intervals up to the time the flowers expand. If you are planting new beds make quite sure the young plants are perfectly free from signs of the disease.

CAPABILITY BROWNE.—C. P., Berks: I have recently been reading a gardening book published some years ago, in which a landscape gardener is frequently mentioned under the designation of "Capability Browne." Perhaps you can tell me something about him.—Launcelot Browne, who became to be very generally known as "Capability" Browne, was a landscape gardener who attained a high position as an exponent of his art about the middle of the 18th century, and this position he maintained until his death, which occurred somewhat suddenly on February 6, 1783. Browne commenced life as a gardener at Stowe, and, possessing a cultivated mind and considerable taste, he soon made headway when he left Stowe and devoted his whole attention to landscape gardening. He was consulted by the majority of those who, in his day, had gardens of importance, and succeeded in amassing a large fortune. He received the designation of "Capability" owing to his usual practice of stating to his patrons after making a survey that the gardens possessed great capabilities; and he appears to have supported his views upon this point by effecting great changes in those gardens which he was engaged to improve. His work was regarded by some of his critics as monotonous and tame, while others bestowed the most lavish praise upon it. His most severe critic was perhaps Sir Uvedale Price, who, in the course of one of his criticisms, writes of "the tameness of the poor pinioned trees of a gentleman's plantation drawn up straight," and describes one of his river banks as the "bare shaven border of a canal." Daines Barrington wrote that Browne "undoubtedly hath great merit in laying out pleasure grounds, but I conceive that in some of his plans I see rather traces of the kitchen gardener of old Stowe than of Poussin or Claude Lorraine." Loudon expressed the opinion that, while Browne possessed considerable talents, he was not imbued with the taste for picturesque beauty which distinguished the work of Kent, Hamilton, and Shenston. Browne was admired by George Mason, who not unreasonably asks "why Browne should be charged with all the defects of those that have called themselves his followers. I have seen no good reason alleged, nor can I suppose it possible to produce one." It would appear from contemporary literature that Loudon's estimate of Browne's abilities may be accepted without any great difficulty.

GROUPS OF SHRUBS WITH COLOURED FOLIAGE.—D. S. S., Sawston: Will you please give me a brief list of shrubs and small trees suitable for bold grouping for effect? Some should be deciduous and some fairly evergreen, as the proposed group is to be within sight of the house.—We suggest the following for your consideration: Prunus Pissardi, P. cerasifera atropurpurea, Berberis vulgaris, B. Thunbergi, Cornus sibirica elegantissima, C. alba späthi, C. Mas argentea variegata, C. controversa variegata, Acer Negundo variegata, and A. N. aureo-variegata, golden privet, forms of Euonymus japonicus, lavender, Santolina chamæcyparisus, golden elder, golden-leaved catalpa, purple hazel, Photinia serrulata, various gold and silver hollies, Eleagnus pungens variegata, and the various gold and silver conifers, provided coniferous plants do well in your district. Arrange the planting so that there is a good background for the group if possible, and see that the dark-leaved subjects are placed so as to throw into sharp relief the golden and silvery-foliaged shrubs.

HARDY AARON'S BEARD.—E. G., Sherborne: In the course of a recent discussion I was given to understand that there is a moisture-loving grass which is practically a hardy counterpart of the very popular Isolepis gracilis, so commonly used as an edging plant in greenhouses and conservatories. My informant could not tell me the name of the plant, but he was very emphatic in his statement that there was such a species.—It may be that your friend has seen Isolepis gracilis (known also as Scirpus riparius and S. nodosus) growing out of doors during the summer in some favoured spot, as it is nearly hardy in the South of England. Possibly, also, the plant referred to is Scirpus setaceus, a British tufted species, that has a distinct resemblance to the popular isolepis; but, after all, we can only make a shrewd guess at the name needed, failing specimens or a more definite description.

IMPROVED WINTER WASH FOR FRUIT TREES.—A. S., Skipton: I believe there is now an improved method of making a caustic wash for spraying fruit trees during winter, and I think it was first tried at the Duke of Bedford's Experimental Fruit Farm. If you can give me the formula I shall be greatly obliged.—The improved wash is used for the same purpose as the caustic soda wash, but is more effective, and in every way superior to it. The wash is the invention of Mr. Spencer Pickering, and has been used with much success at the Woburn Experimental Fruit Farm. To make 10 gallons of wash Mr. Pickering recommends: Iron sulphate ½lb., lime ¼lb., caustic soda 2lbs., paraffin 5 pints, and water to make 10 gallons. Dissolve the iron sulphate in about 9 gallons of water, slake the lime with a little water, and then add sufficient to make it into a milk; strain this through a piece of sacking, and add to the iron sulphate solution. Churn the paraffin into the mixture, and add the caustic soda, and when this has dissolved the wash will be ready for use. By the addition of paraffin the work is rendered more efficient in the destruction of mussel scale, and the use of iron sulphate ensures the emulsification of the paraffin.

SPOTS ON ODONTOGLOSSUM LEAVES.—P. T., New Brighton: I am sending you a few odontoglossum leaves which are more or less spotted, in the hope that you will be able to tell me the reason for such spotting and the cure.—Spotting is due chiefly to a combination of low temperature and excessive moisture. The moisture in the air condenses on the leaves at night and forms drops, and when the temperature falls low these drops of water severely chill the tissues and disease is set up. More fire-heat accompanied by ventilation will improve matters; give water with great care, and avoid excessive damping down at this season of the year.

NAMES OF PLANTS.

C. R., Dalkey.—1, Escallonia macrantha; 2, Stokesia cyanea.

G. S., Liskeard.—1, Veronica Traversi; 2, V. Andersoni variegata.

M. M. J., Beverley.—1, Aglaonema costata; 2, Adiantum fissum; 3, Polypodium vulgare cambricum.

J. A. S., Harrogate.—1, Sedum spectabile; 2, Kniphofia rufa; 3, Tamarix gallica; 4, Leycesteria formosa.

F. H. W., Frinton.—1, Probably Amelanchier canadensis, send when in flower, next spring; 2, Sarracenia Drummondi; 3, Strobilanthes Dyerianus; 4, Acer colchicum rubrum; 5, Clematis integrifolia.

HOLLYHOCKS.

Can any reader of, or advertiser in, THE GARDENERS' MAGAZINE recommend a strain free from the fateful fungus? We do not grow old plants, and we most carefully spray, yet the foliage of our hollyhocks would be "a disgrace to a gibbet." Has anyone a single healthy hollyhock? I went to Kew a short time ago, and found the plants even worse than those in my garden; and at the Horticultural Hall this year I saw a group of fine spikes, yet not one had clean or healthy foliage. Hollyhocks are (or shall I say, should be) a feature of my borders, and I should regret to give up growing them.

F. R. H. S.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Autumn Flowers.

Although we may not be able to accept without some reservation Donne's opinion, as expressed in his lines wherein he states—

"No spring or summer beauty hath such grace,
As I have seen in one autumnal face"—

we have no hesitation in declaring that the hardy plants which flower after the summer has departed are more than sufficient to admit of the enjoyment of floral effects of surpassing beauty during the greater part of the autumn season. In the olden days, when tender bedding plants were allowed to usurp the whole of the available space in the beds and borders of the flower garden, the production of displays of autumn flowers other than those yielded by plants under glass was an impossibility. Consequently, with the close of the summer, with its warmth and sunshine, flowers vanished from the garden, and left bed and border bare until the following summer, except in those gardens wherein the practice was adopted of filling the beds with spring-flowering plants on their being cleared of their summer occupants. Of autumn flowers there were none, and this state of things continued long after the tender summer flowers had fallen from their high estate, with the result of the garden being wanting in interest and attractiveness at a time when the country house usually contains a goodly contingent of visitors. In the course of time a change was brought about by the inclusion in the selections of hardy plants of a small number of kinds that bloom in the autumn, and their presence was indicated by a few patches of colour scattered over the border. Within the past few years an important reform has been effected in the arrangement of hardy plant borders; and, mainly as the result of our advocacy, increased attention has been given to the production of seasonal displays of flowers. In some cases strenuous endeavour has been made to utilise such kinds as will maintain a procession of flowers extending from about the middle of spring until the autumn is well advanced. In not a few gardens the practice has been to have the beds bright with the colour of bulbous and fibrous-rooted plants, and to devote the borders to hardy perennials that bloom during the summer and autumn, and this method of procedure has much to recommend it. Where, on the other hand, the pleasure grounds are sufficiently extensive to allow of two distinct sets of borders, the arrangement of one with plants which bloom during the greater part of the spring and summer, and the other with kinds which will maintain a succession of flowers from the closing days of the last-mentioned season until the end of the autumn, will be found eminently satisfactory. Whatever be the dimensions and design of the garden, an endeavour should be made to have it bright with the flowers during September and October. In some seasons the rains and early frosts may greatly mar their beauty and diminish the opportunities for the enjoyment of the charms of the flowers in the open, but in the majority the weather is such as to admit of the flowers attaining their full development, and also of their being fully enjoyed. The hardy plants that bloom somewhat late in the year would make a somewhat lengthy list, but we are not so much concerned at the present time with kinds that require special treatment or claim attention more for their interest than for their attractiveness, as with those which under ordinary culture are capable of producing colour effects of sufficient brightness to dispel the gloom that is sometimes cast over the flower garden during the present month. To mention but a few of the plants suitable for beautifying the flower garden during the season on which we have recently entered there are the Japanese anemones, which now form a rather large group; the perennial asters, or Michaelmas daisies, in great variety; the stately Artemisia lactiflora, heleniums, helianthuses, kniphofias or torch lilies, perennial lobelias, and rudbeckias. In selecting from each of these groups it will be necessary to give preference to those of which the flowering extends over the greater part of September and October. The Japanese anemones are sufficiently numerous to afford ample opportunities for the exercise of taste and judgment in making a selection, and to contribute liberally to the attractions of the hardy flower border. The variety known as A. japonica alba has not, perhaps, any superior among the pure white varieties, but there are other white forms that should be selected, and such rose and pink varieties as Monte Rosa, Prince Heinrich, and Queen Charlotte should be grown in preference to the type, which is by no means wanting in attractiveness. The Michaelmas daisies have undergone considerable improvement of late years, and some at least of the more recent introductions should have a place in borders of the most limited dimensions. The amellus section comprises a considerable number of varieties, all of which have a dwarf upright habit, and bear large flowers of various shades of deep blue and purple-blue. The cordifolius varieties are remarkable for their elegant habit and freedom of flowering, and the colours range from white to pale blue and mauve; not less attractive are the forms belonging to the ericioides groups, for they have a graceful

MR. H. G. MOUNT.

habit, and bear a profusion of flowers, the colours including blue, mauve, pink, and white. Very distinct from the foregoing are the Novæ Angliæ and Novæ Belgi varieties, which are rather later, more robust in growth, and have large flowers, with a considerable diversity of colour. Especially noteworthy among the Novæ Angliæ forms, which continue in bloom until November, are Lil Fardell, Mrs. J. F. Rayner, Mrs. S. T. Wright, and W. Bowman, these affording rich shades of crimson. From the Novæ Belgi section should be selected such beautiful varieties as Beauty of Colwall, Climax, Daisy Peters, Miss Southall, Perry's Pink, St. Egwin, and William Marshall. There are many other Michaelmas daisies, but a few only are mentioned to indicate the most useful types. Riverton Beauty and Riverton Gem are of special value among the heleniums, because of their attractiveness and the late period at which they bloom. The sunflowers include several species and varieties of a high degree of utility for late autumn-flowering, and the best of these are Helianthus mollis, and its narrow-leaved form, H. multiflorus, and its varieties Bouquet d'Or and Soleil d'Or; H. orgyalis, tall in growth; the variety of H. rigidus known as the Rev. Wolley Dod; and H. sparsiflorus, the last-named one of the finest of the tall sunflowers, although very slow in making its way into gardens. The perennial lobelias are not sufficiently hardy to withstand the effects of exposure to English winters, but with the aid of an unheated frame they can be successfully utilised in beautifying in the autumn borders devoted to herbaceous plants. In addition to the foregoing, there are now at the command of cultivators a large number of border chrysanthemums of much merit, and as they can be grown in the border from the first, or in the reserve ground, and be transferred to the border early in September, their value is high for the purpose now under consideration, and especially those with brightly-coloured flowers.

Mr. H. G. Mount is comparatively young in years but ripe in experience, and for a quite long period has occupied a leading position among those who are actively engaged in the cultivation of roses for commercial purposes, and is held in high estimation both for his knowledge of these flowers and his personal qualities. As so well known to those of our readers who are keenly interested in roses, the firm of Messrs. George Mount and Sons, of which Mr. H. G. Mount is a member, have from the first devoted special attention to roses, and that some twenty or more years ago they engaged in rose culture under glass for the production of cut flowers, and very quickly distinguished themselves in this branch of their activities. They have, indeed, been so successful therein that for many years past their fine groups of splendidly-developed long-stemmed blooms of varieties specially suitable for floral arrangements in a cut state have formed at the spring exhibitions of the Royal Horticultural Society and elsewhere features remarkable alike for their attractiveness and interest, and useful as object-lessons in the art of rose culture under glass. It may be assumed that much of the success that has been achieved by the firm in this aspect of their business is largely due to the skill and judgment of Mr. H. G. Mount, and it is certainly due to his taste that the blooms are presented to public notice in so delightful a manner as to at once command attention and impress those who have an opportunity of seeing them, for many are the occasions that we have seen him busily engaged in the arrangement of the groups. For some years Mr. H. G. Mount has been a member of the Council of the National Rose Society, and his thorough acquaintance with the society and its work, the moderation of his views on questions of policy, and clearness of expression, are such as to ensure his having the attention of his fellow-members when taking part in discussions.

The Wallichian Collection of Dried Plants, which was presented to the Linnean Society by the East India Company in 1832, has been given to the Royal Gardens, Kew. This collection resulted from the labour of König, Roxburgh, Rottler, Klein, Hamilton, Heyne, Finlayson, Wallich, and Linnæus; and since it came into the possession of the Linnean Society additions have been made to it by Dr. Horsfield and others. In 1857 it was moved from Soho Square to Burlington House, and in 1873 it was transferred to the apartments occupied by the society. In 1873 increased demands for space led to the removal of the cabinets from council room to the old post office, and recently there has been so great an increase in the demand for space, that the Linnean Society was induced to offer the collection to Kew, and this offer was readily accepted.

Fruit Show and Conference at Dublin.—In connection with the forthcoming Winter Fruit and Flower Show of the Royal Horticultural Society of Ireland, which is to be held in the Royal Dublin Society's premises at Ballsbridge on the 22nd and 23rd inst., it is proposed to hold on the opening day of the show a conference of those interested in the Irish fruit-growing industry. The conference will be addressed by well-known fruit-growers and others having expert knowledge of the subject, and it is hoped by the Irish Department of Agriculture that all persons interested in this important industry will endeavour to be present and take part in the deliberations.

Appointment of Lecturers at Aberdeen.—The Governors of the Aberdeen and North of Scotland College of Agriculture have filled the vacant lectureships in Forestry and Horticulture. To the first-mentioned post Mr. Peter Leslie, a graduate of Aberdeen University, was appointed. A native of Edenkillie, Morayshire, Mr. Leslie, after graduating, had several years' teaching experience as a science master. He then returned to Aberdeen University for the purpose of completing the degrees of Bachelor of Agriculture and Bachelor of Pure Science. As part of the curriculum of study for the former degree, he attended the classes in forestry. Mr. Leslie was awarded a Carnegie scholarship, which enabled him to proceed to Munich University, Germany, to further specialise in the subject of forestry. Returning to Aberdeen, he was appointed Assistant Lecturer in Forestry at the University, a position which he has held up to the present time. Mr. George E. Greenhow was appointed to the Lectureship in Horticulture. A native of Cumberland, Mr. Greenhow has had an extensive experience in the culture of fruit, flowers, and vegetables under glass and in the open, having entered upon his gardening career by serving an apprenticeship in the gardens at Hutton-in-the-Forest, Cumberland, the seat of Sir Henry Vane, Bart., and serving in several of the leading private gardens. During 1904-5 he was employed as gardener to the Northumberland County Council at Cockle Park, Morpeth, where he had charge of the horticultural and forestry sections. He left Cockle Park to undergo a course of training in the Royal Botanical Gardens, Edinburgh, where he had considerable experience in public garden work. Since leaving the Royal Botanic Gardens (in 1909) he has been Assistant Lecturer in Horticulture in the Edinburgh and East of Scotland Agricultural College.

Soil Science.—At the meeting of the London Branch of the British Gardeners' Association, which will be held on Thursday next (October 9), Mr. G. P. Berry, Chief Inspector of the Horticultural Branch of the Board of Agriculture, will give a lecture on "Some Causes of Soil Fertility and Poverty." The meeting will be held at Carr's Restaurant, 264, Strand, London, and commences at 8 p.m. As all gardeners are invited, there should be a large audience, for the subject is one of much importance to cultivators, and Mr. Berry's abilities as a lecturer are exceptionally high.

The Late Mr. Robert Sydenham left estate valued at £13,374. He bequeathed considerable sums to his married daughters; £100 to his secretary, Mr. Herbert Smith; £100 each to his executors, and the bulk of his property, in trust for life, to Mrs. Sydenham, with certain bequests to horticultural and other charities, subject to certain circumstances and conditions, with ultimate residue, in trust for life, to his daughters.

Roof Gardens for the Babies.—A philanthropic lady-landlord in New York has built a block of flats, or apartments, for the working classes, and has not only provided a special room in the basement for the storage of perambulators and mail carts, but has so arranged matters that each set of apartments has its own roof garden, properly wired in and with an awning in summer, where the babies can play. Suitable trees and shrubs are to be planted, so that whatever the time of year there will be green leafage in these babies' gardens.

Sterilisation of Seeds.—In the "Kew Bulletin" (No. 5, 1913), Miss Massee has contributed a report of much interest on the experiments she has carried out with a view to determine the relative merits of the various methods of seed sterilisation. Miss Massee refers to the fact that, owing to the unsatisfactory results obtained from the practice usually adopted, de Zeeuw experimented with various other methods, and decided in favour of hydrogen peroxide, and found that Pinoy and Mogrou also obtained favourable results in the use of this substance. The last-named authors found that after seeds had been immersed in hydrogen peroxide for five hours all the spores were killed, without the germination of the seed having been much retarded, and in certain cases it was accelerated. These experiments were conducted with the object of obtaining for physiological research seeds absolutely free from living germs, more especially bacteria. It was suggested to Miss Massee by her father, Mr. G. Massee, that the action of hydrogen peroxide on fungus spores and on the germination of seeds might prove to be of great value in preventing the spread of plant diseases due to the presence of spores on the seed. For the purpose of testing this Miss Massee made a series of experiments in the Jodrell laboratory at Kew. In order to test the action of hydrogen peroxide on the vitality of seeds, two batches of each kind experimented on were soaked in hydrogen peroxide for four and twenty-four hours respectively. A control batch of each kind of seed was soaked in water for a corresponding length of time. It

found that the spores of fungi, and also some kinds of bacteria, are, as a rule, killed by an hour's immersion in hydrogen peroxide; no spores experimented with germinated after similar treatment for two hours. In nearly every instance the germination of seeds immersed in hydrogen peroxide was retarded, and the plants raised from seed immersed for four hours were one or two days later in making their appearance above ground than those raised from untreated seed. Seeds immersed for twenty-four hours were retarded from two to eight or killed outright. After treated seeds have germinated the growth of the plants is very rapid. For all practical purposes soaking seeds in hydrogen peroxide for three hours will kill all superficial fungus spores without injury to the seeds. This method is, according to Miss Massee, preferable to fumigation, which, as a rule, does not kill fungus spores, unless continued for such a time as to damage the seeds.

Professor W. Bateson, F.R.S., has been elected president of the British Association for next year, when the meeting will be held in Australia. Mr. Bateson, when occupying an important position in the Cambridge University, became a prominent exponent of the Mendelian theory of heredity, and mainly as the result of his researches in connection therewith he was appointed to the newly-created Chair of Biology. This he occupied until he was appointed the first director of the John Innes Horticultural Institute at Merton.

The Veitchian Orchids.—We are informed that Messrs. Flory and Black have purchased the whole of the orchids, including the home-raised hybrids, belonging to Messrs. Jas. Veitch and Sons, Chelsea. This collection has been cultivated at the Langley Nurseries, and the purchasers have also taken over the orchid houses, private house, and immediate surroundings at Langley, and will carry on business there under the title of Messrs. Flory and Black. Mr. Flory, nephew of the late Mr. H. A. Tracy, has had a long experience at his uncle's nursery at Amyard Park, Twickenham, which he still controls; and Mr. Black has for many years been a very successful grower and raiser, in charge of the collection of R. G. Thwaites, Esq., at Streatham. Every good wish will be extended to these gentlemen in their new enterprise.

The Scottish Thistle.—There is great trouble because someone has found that a Kew Hand List gives Onopordon acanthium as the Scottish Thistle, whereas Scotsmen think the national emblem is Carduus or Cnicus lanceolatus, which Kew describes, or degrades, as the Burr Thistle. Many common British plants have more than one popular name, and probably this is the cause of the trouble, but if "the rough burr-thistle" of Burns is the true Scottish thistle, there should be no difficulty in deciding the point. But who is to be the authority that shall decide between Onopordon and Cnicus? Who better than Professor Bayley Balfour, of Edinburgh Botanic Gardens, to decide this thistly point?

American Gooseberry Mildew.—A few days since three fruit-growers from different parts of the country were summoned at the Bow Street Police Court for having during the past summer caused to be exposed for sale at Covent Garden a quantity of gooseberries affected with the American gooseberry mildew. Fines ranging from 20s. to 5s., with costs, were imposed.

NEW PLANTS, FLOWERS, AND FRUITS.

CATTLEYA CYBELE.

A very beautiful cattleya with blush-white sepals and petals, and white lip, finely marked with bright violet-purple, especially close to the apex. A.M., R.H.S., September 23. Mr. E. H. Davidson, Orchid Dene, Twyford, Berks.

LÆLIO-CATTLEYA ARMADA.

This very handsome orchid is the result of crossing L.-c. luminosa with C. fulvescens. It has flowers of fairly good size and form, and of distinct colouring. The sepals and petals are cream-coloured, tinted with purplish-yellow, while the lip is yellow with markings of purple towards the apex. A.M., R.H.S., September 23. Lieut.-Col. Sir G. Holford (grower, Mr. H. Alexander), Westonbirt, Gloucester.

ASTER BEAUTY OF RONSDORF.

Flowers very large, the colour violet-blue. A.M., R.H.S., September 23. Messrs. T. S. Ware, Lim.

ROSE MOONLIGHT.

We have previously referred to this hybrid tea, semi-double rose, which produces its creamy flowers in large elegant clusters. A.M., R.H.S., September 23. Rev. J. H. Pemberton, Havering, Romford.

CARNATIONS.

Fairmount.—A new American perpetual variety of large size. It is apparently a good grower. The colour is soft heliotrope with a French-grey suffusion. A.M., R.H.S., September 23. Mesrs. Allwood Brothers, Wivelsfield, Sussex.

Salmon King. — A beautiful home-raised perpetual variety with very shapely, bright salmon flowers, that are sweetly-scented, and have petals so smoothly edged as to bring the variety almost up to florists' standard. A free-flowering carnation of great merit. A.M., R.H.S., September 23. Messrs. Stuart Low and Co., Enfield.

PERENNIAL ASTERS.

Beauty of Ronsdorf.—A showy variety of the Amellus section, dwarf, free, and bearing large flowers of a very attractive shade of light violet-blue. A.M., R.H.S., September 23. Messrs. Thos. S. Ware, Lim., Feltham.

Mrs. Frank Penn.—A brilliant rose-purple variety of the Novi-Belgi group, bearing its abundant flowers in large, elegant clusters on wiry, dark stems, with dark foliage. A.M., R.H.S., September 23. Mr. H. J. Jones, Ryecroft Nursery, Lewisham.

CHRYSANTHEMUMS.

Olive.—A very useful early variety, with medium-sized flowers, carried in elegant sprays on stiff stems. The colour is bright chestnut-red, with yellow reverse, and very effective. It is classified as: Japanese, sub-section 1 c. F.C.C., N.C.S., September 22; A.M., R.H.S., September 23. Messrs. W. Wells and Co., Merstham.

Susie.—A very bright and distinctive early single variety, bearing its flowers in great profusion on stiff sprays. The colour is charming, and may be best described as salmon-buff Class: Single, sub-section 2 b. Commendation, September 22. Messrs. W. Wells and Co., Merstham.

Golden Firebrand.—A single variety with several rows of florets. It is golden-yellow, and the flowers are borne in large sprays and on very long, wiry black stems. If any fault can be found it is the dearth of foliage on the flower stems. The variety is a sport from the crimson Firebrand. Class: Single, sub-section 2 a. Commendation, N.C.S., September 22. Messrs. W. Wells and Co., Merstham.

DAHLIAS.

Homere.—A big cactus dahlia of full exhibition size, and with the incurved spiky end to the florets that commend a flower to so many exhibitors. The colour is dark and deep crimson-maroon. A.M., R.H.S., and F.C.C., N.D.S. Messrs. J. Burrell and Co., Cambridge.

Ruby.—A very neat and shapely pompon dahlia with bright ruby-red flowers. A.M., R.H.S.; F.C.C., N.D.S., September 23. Messrs. J. Cheal and Sons, Crawley.

Rupert. — A stiff-stemmed, erect garden cactus dahlia, with flowers of a bright yellow and apricot colouring. A.M., R.H.S., September 23. Mr. H. Shoesmith, Woking.

Reginald Cory.—A very distinct decorative dahlia like an enlarged pompon variety, the basal colouring bright scarlet, the tips of the florets shading from the red to pure white. A.M., R.H.S., September 23. Messrs. J. Cheal and Sons, Crawley.

Mrs. J. G. Vaughan.—A very fine pæony-flowered dahlia, with narrower florets than usual, and these incurved a little, as in so many cactus varieties. The colour is wholly of a soft yellow shade. A.M., R.H.S., September 23. Messrs. Warnaar and Co., Sassenheim, Holland.

Herzogin von Braunschweig (or Duchess of Brunswick).—A splendid and effective pæony-flowered dahlia of fine size, the colouring being rich orange-salmon, or flame colour. A.M., R.H.S., September 23. Messrs. Warnaar and Co., Sassenheim.

BERBERIS AGGREGATA.

A neat-growing species from China, and one that is likely to prove suitable for the rock garden or for covert planting. About twenty inches high, its growths are clothed with whorls of small, neat green leaves, slightly spiny. The small berries are very freely produced, and are straw-coloured, tinted with pink, and almost transparent. A.M., R.H.S., September 23. The Hon. Vicary Gibbs (gardener, Mr. E. Beckett), Aldenham House, Elstree.

PRIMULA VINCÆFLORA.

Discovered by the Abbe Delavay about thirty years ago, this very interesting Chinese species has recently come into cultivation through the efforts of Mr. G. Forrest when collecting for Messrs. Bees, Lim. It is a tiny plant, about three inches high, with broad, roundish leaves, produced in a rosette, and reminding one of a pinguicula. The flower stem is erect, sturdy, and bears a solitary flower, which is carried a trifle below the horizontal, and is large for the size of the plant, long-tubed, with deeply-divided lobes, the colouring being violet with an eye of deeper shade. A specimen has lately flowered in the Edinburgh Botanic Gardens, and was exhibited at Westminster on September 23. A.M., R.H.S., September 23. Professor I. Bayley Balfour, F.R.S., Edinburgh Botanic Garden.

MERRYWEATHER DAMSON.

We described and illustrated this very fine fruit in our issue of October 28, 1911. It is of the size of a small plum, and larger than most prune fruits. It is of dark purple colouring, crops abundantly and regularly, is good for dessert when quite ripe, and splendid for culinary purposes. As a late autumn fruit, it is of high merit, and should be borne in mind for future planting. It received an Award of Merit from the Royal Horticultural Society at the fruit show held in 1911, and a F.C.C. at the R.H.S. fruit show on September 25. The higher award is well deserved. Messrs. Merryweather and Son, Southwell, Notts.

Heliotrope.—This is another favourite plant for growing against the roof of the greenhouse, and needs very similar treatment to the fuchsia. Cuttings may be inserted at the present time to produce plants for making large specimens, but for flowering in small pots cuttings are best rooted in early spring.—E. Harriss.

CHRYSANTHEMUM NOTES.

The recent steady rains have moistened the soil to a considerable depth, and, as a result, the work of lifting and potting planted-out specimens has been greatly facilitated.

Young plants which were put out last spring may be lifted without any prior preparation and potted forthwith. Their roots will not be beyond control, and, as pots of various sizes may be used, there need be no difficulty in placing all the roots in them with a fair amount of garden soil attached. But a good compost should be mixed in which to pot the varieties from the open border as fresh roots grow, and if these permeate the rich loam, the buds, as they develop, will gain much strength.

Where flower pots are scarce and cannot be spared, the lifted plants may be placed on a peach-house border, and the roots neatly covered with the prepared compost—loam, leaf-soil, and road grit or coarse sand. If a few stakes are driven into the border and some twine passed through the branches and fastened to them, the plants will not require any separate staking.

December and Christmas Flowering Plants.

There are some splendid batches of plants of varieties for late flowering in many gardens this year. The growth is even, fairly well matured, and very healthy. But it is a very easy matter to spoil the plants in the course of the next few weeks by placing them behind walls and in similar positions where the maximum amount of light at this season cannot reach them. Placing the plants in such positions is done to retard bud development, but it has not the desired effect to the extent one would think; in fact, it is a means of hastening forward the buds, as I proved many years ago.

Having put some plants on the north side of a high wall, and left others in the open quarters, I found that the buds on the latter were later than on the wall-protected ones. The stems of the plants in the open hardened too, while those of the plants behind the wall became very soft.

The best plan is to leave the late-flowering plants in the open, and put up a light framework over them to support mats or tiffany, which should be put on if the nights are frosty. The housing of these plants in the southern counties need not be done until the month of October is well advanced.

Plants Trained on Walls.

Chrysanthemums look charming when their branches are trained on walls. September and October-flowering varieties are mainly used for this purpose, and where both tall and dwarf-growing ones are planted alternately, the whole of the wall space is evenly covered. The upper twelve inches of each stem should be allowed to depend freely from the wall, then the blooms will be seen to the best advantage, and they will receive quite enough protection.

Single-flowered Varieties.

There are many classes provided in exhibition schedules now for this lovely section, and, as the buds do not take a long time to open, the plants must be kept in cool positions as long as possible, so that the flowers will be quite fresh when wanted for the November shows. A few of the very early-flowering varieties, which, owing to late pinching, have been slow in showing buds, must be disbudded as soon as possible. The bulk of the buds of singles, however, will be swelling nicely, and all plants bearing such must be placed under cover before the colour of their florets is seen.

Geo. Garner.

AURICULAS.

The coolish, dry summer seems to have suited the plants well, and they are now completing their autumn growth, and getting ready to face the winter.

They are mostly, as I like to see them at this time, with short, fleshy leaves, some like green rosettes; others with flat leaves and rather starry; and others of an intermediate type, but all that are healthy have short, thick leaves. It is now time for cultivators who have grown their plants in the open to put them under cover in their winter quarters, for heavy rains can now do them no good. It is well at the present time to look out for caterpillars, which do a lot of harm to plants that have been in the open. I do not know of any of these pests that have a special liking for the auricula, but many of them are general feeders, and will polish off a George Lightbody or a Harrison Weir if they can get them, although they would quite as soon feed on groundsel.

When the plants are housed for the winter all that is wanted is to give them plenty of air, night and day, to water them as long as the weather is mild, and, when winter sets in to keep them dry, and give them all the air and sun possible. Auriculas don't mind frost a bit in winter, so long as their quarters are airy and dry. I believe they would resist Arctic conditions treated thus in winter, but when spring comes, and they begin to grow, one must see that no spring frost checks their development.

These remarks apply also to alpine auriculas, although they are not so liable to be checked in spring by frost, their petals not being so thick and fleshy as those of show varieties.

I love the alpines. They are easy to grow, and so diverse in their colourings, and so ready to present one with improved varieties by sensible cross-fertilisation, that one cannot help it.

The show varieties need a Horner, a Simonite, or a Douglas to make any impression on standard sorts, and, alas! these men are gone to their rest; but let us keep trying. It may, perhaps, be useful if I say what, in my opinion, are the best sorts to grow.

Green Edges.—Mrs. Henwood, Shirley Hibberd, and Orient.

Grey Edges.—George Lightbody, George Rudd, and Olympus.

White Edges. — Acme, Conservative, Traill's Beauty, and Heather Bell.

Selfs.—Mrs. Potts, Ruby, Favourite, Harrison Weir, and Mikado.

J. W. Bentley.

Stakehill, Manchester.

Lilium sulphureum. — It is now twenty-four years since this lily, which comes from Upper Burmah, created quite a furore when it was first shown at a meeting of the Royal Horticultural Society, and a first-class certificate awarded it under the name of L. Wallichianum superbum. Since then it has been assigned specific rank under the name of L. sulphureum, and has also proved to be very amenable to cultivation in this country. In many districts it is from its late-flowering qualities, chiefly regarded as a lily for the decoration of the conservatory, as out of doors many of the flowers do not expand before the nights begin to get cold. It is a tall and stately lily, while the large trumpet-shaped flowers are yellowish in the interior, and on the outside tinged with red. A year before the introduction of this species we made the acquaintance of Lilium nepalense, a striking lily, whose flowers are prettily reflexed, and yellowish-green with purple centre.—S.W.

SOME OF THE NEWER SWEET PEAS.

The season of 1913 has not been so productive of new sweet peas as some previous years. Nevertheless, there are a few that the sweet pea enthusiast must secure if he wishes to be quite up-to-date.

Year by year the work of the raiser becomes more difficult, and, seeing the very many varieties that we have had during recent years, it is not surprising to find that real novelties are much more difficult to obtain, and the demand for good things is so great that the raiser has to withhold his novelty for a season or two so as to be able to supply all demands when it is put on the market. Unfortunately, the newer waved varieties become more than ever shy in seeding, and in such seasons as the past two or three, even when great care and attention is paid to the matter, extremely poor crops have been recorded, and it may happen that once we obtain a good seed year we may be inundated with novelties.

King White (Burpee and Dickson) is one of the varieties that was eagerly looked forward to in 1913, and, judging by the way this fine white variety has been exhibited, it should find a place in most collections in 1914.

Florence Wright Spencer (Stark) may not be quite so large, but it is a pea of extremely good quality, which will make quite a bold bid for supremacy.

Stevenson's White (J. Stevenson) is another which is well worth a trial, and probably the purest and best frilled white we have; not having grown it from autumn-sown plants, I am not quite sure whether it has quite the size of the two first mentioned.

Constance Hinton (Hinton) has not been seen sufficiently to enable one to say quite whether it comes up to its promise of last year, but either of these white varieties is good enough to replace the old favourite Etta Dyke.

Mrs. McIlwrick (Dobbie) was shown extremely well in the early part of the year, its rose standard and mauve wings being very pleasing, but after seeing it growing outside, I am inclined to think it will prove a better for indoors than outdoors. I hope I may be mistaken, as it is so large and good.

Margaret Atlee, of American introduction, is, I think, one of the best things of the year; it may be termed a glorified Constance Oliver, with more colour and quality, and may prove quite the best variety in the deep cream pink section.

Agricola (Bolton), as an exhibition pea, is distinctly good, and though not at all decided in colour, it makes a bunch that can hardly be put in the wrong position, and I must confess it has agreeably surprised me this year.

Muriel Quick (Unwin) is another of the soft lavender-blush varieties which is extremely pleasing for all classes of decoration.

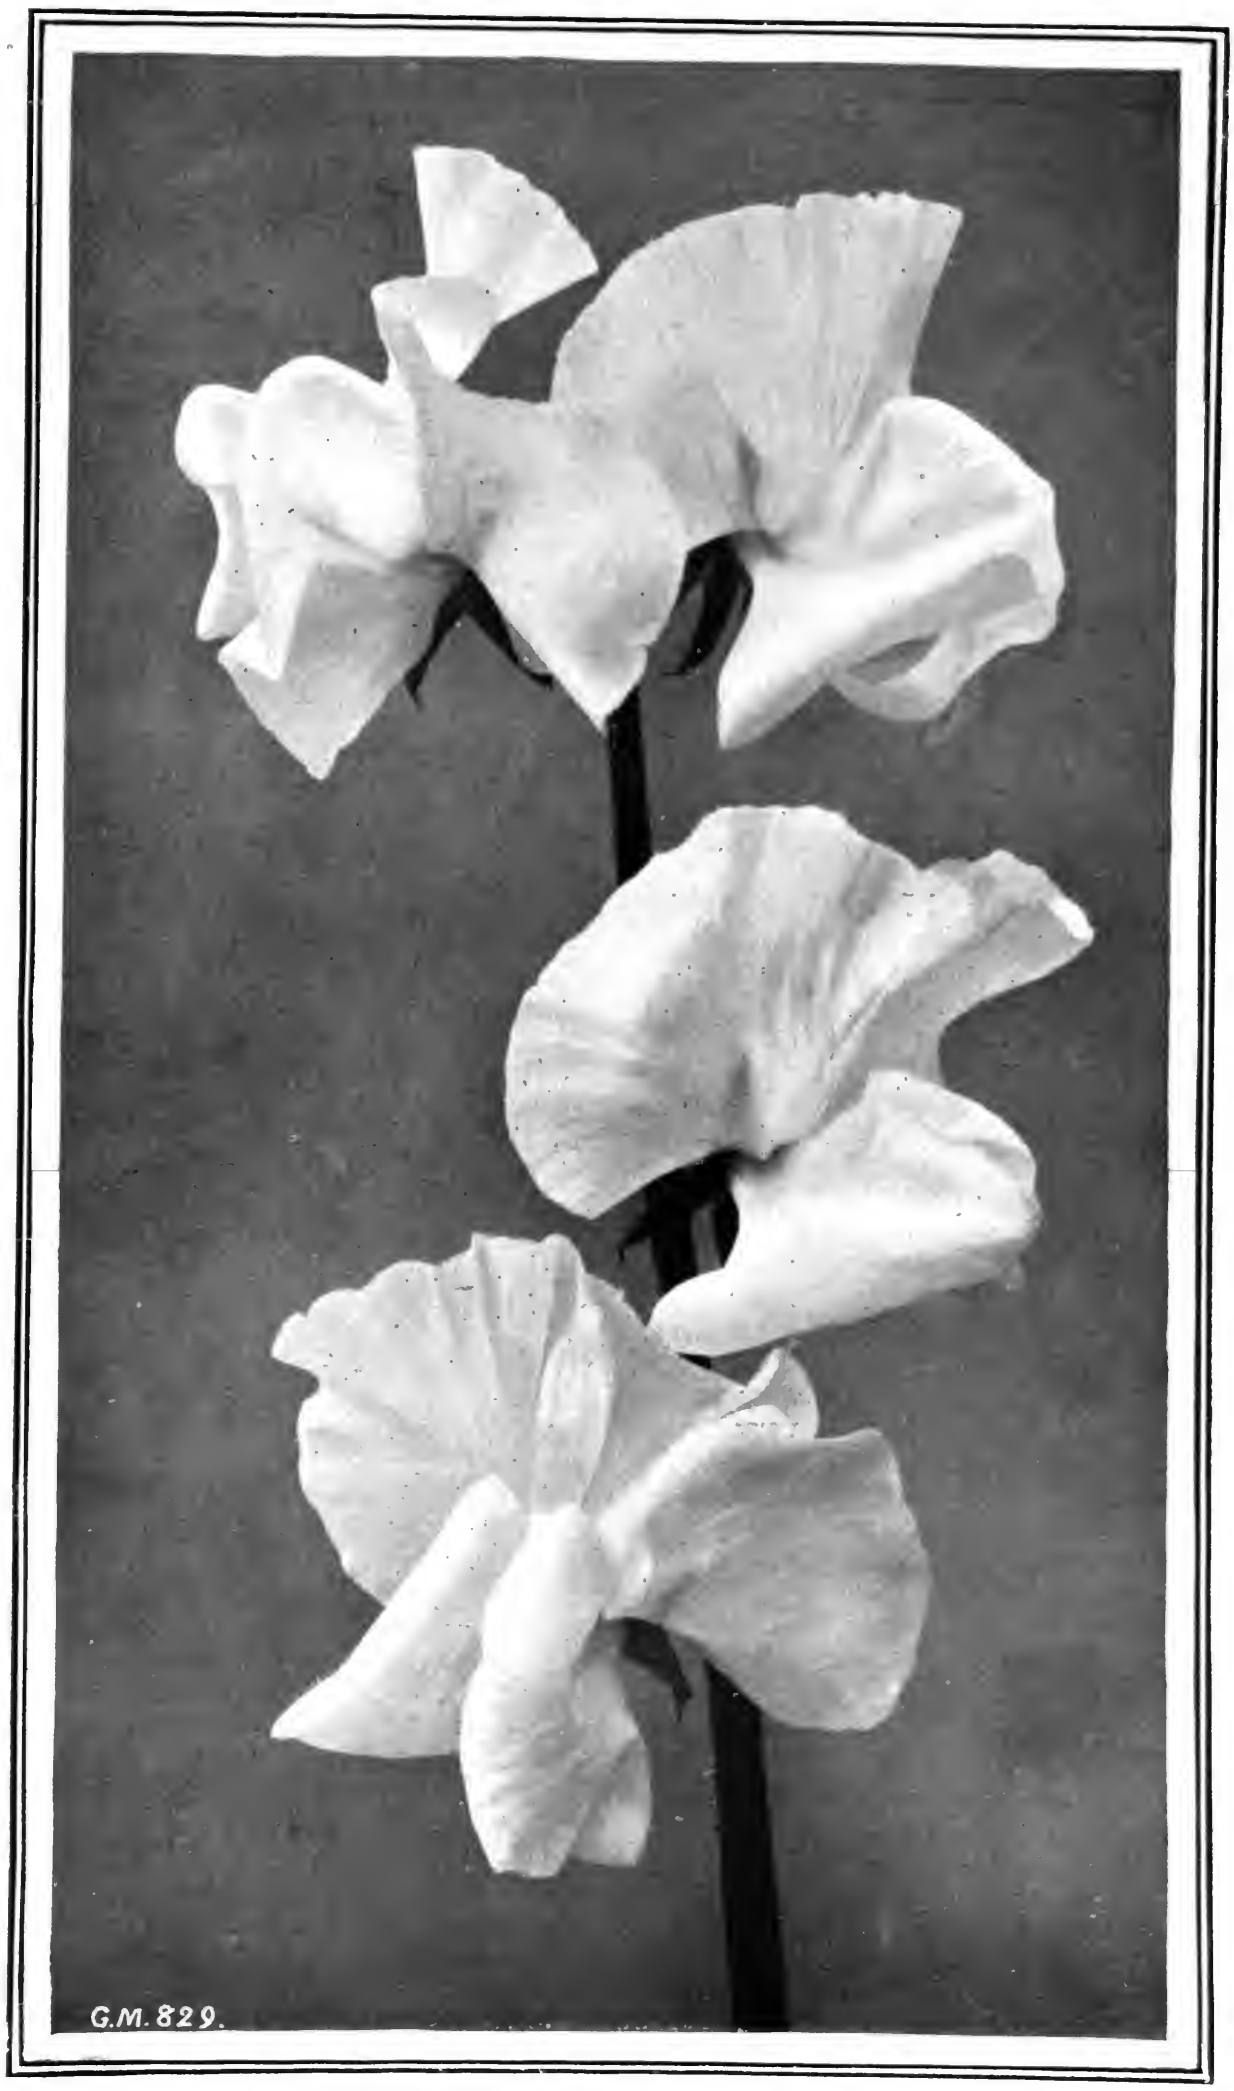
Blue Picotee (Dobbie), as the name implies, is a very dainty blue-edged variety, especially when grown under glass; outside it is like a pale Mrs. Townsend, with, perhaps, a little more "body" in the flower.

King Alfred (Breadmore), a variety noted in 1912, has proved a real giant in the orange-pink class; it closely resembles Edrom Beauty, though possibly a little deeper in colour.

Orange Perfection (J. Box), is another addition to this class, being a giant self-coloured flower, which reminds me very much of Bolton's Pink.

Robert Sydenham (Holmes), is probably the most distinct pea seen for some time. It is rather deeper in colour than Sterling Stent at its best, with the size and shape of Thomas Stevenson, and may be termed a self orange-coloured variety. The demand for this is so great that I understand it will not be put on the market until 1915.

Royal Purple (Wright), is another variety, very distinct in colour, and, though not a giant, a bunch of it should



SWEET PEA KING WHITE.

Flowers pure white. Introduced by Messrs. W. Atlee Burpee and Co. and Messrs. Alex. Dickson and Sons.

Double Maggie Stark (Stark), is still another in this shade of colour. As the name implies, it throws double standards freely, and for this reason it may prove a really good addition to the market varieties.

prove most effective in a collection or decorative scheme, as it is totally distinct from anything else we have among the purples.

Phyllis (Unwin) is a pure white-ground form of the popular variety, Mrs. W. J. Unwin, being even more dainty and pleasing than the latter, the distinct white margin to its standard making it very attractive.

New Marquis (Dobbie) is probably a fine strain of the old favourite, and if quite fixed, and gives four flowers on a stem, it will quickly become popular among the rose-mauve shades.

Mrs. J. C. House (House) is another variety of much the same colour as the last. With me it has certainly done better than Tennant Spencer and Queen of Norway.

Kathleen (Deal) is a delightful sweet pea, deep cerise in colour, and though not quite up to first exhibition size, it should be grown for its colour alone.

Lady Miller (Dobbie) has been exhibited now and again grandly, and when it is in good form it is extremely striking in colour and quality. It is not everybody's variety out of doors, because it bleaches or burns in some situations, but under glass it is one of the best sweet peas we have.

Marks Tey (Dobbie), a 1912 novelty, is a very strong-growing variety, which makes a good bunch for exhibition, and is easily one of the largest varieties.

Prince George (Bolton) has this season decidedly improved its reputation, its distinct colouring being noticeable in a great many winning stands.

Birdbrook, another of Mr. Bolton's 1912 novelties, has found many friends, its finer markings making it preferable to the other varieties in the chocolate-flaked class.

Ruby Palmer (Dobbie) is a fine sweet pea of a peculiar shade of crimson, and, though distinct enough from Sunproof Crimson, I do not think it will supersede that variety for general purposes.

James Box (Box) and Inspector (Dobbie), two salmon varieties, are practically synonymous, and just a little softer in colour than Barbara and Melba; if anything, they are stronger growers, while the shape of the flowers and their position on the stem make them quite distinct from the two last-named.

The above list does not by any means include all the new varieties I have seen, or that may be put upon the market this autumn, but they are all of some merit, and where I find a variety will do better under glass than out of doors, I have given it credit for that purpose, as this phase of sweet pea cultivation is now a very important one, and it is certainly very necessary when growing these flowers under glass to select those varieties which keep their colour well. The experience of those who grow sweet peas under glass in large quantities shows that orange-coloured varieties are far and away the best, followed by the cream and salmon-pinks, with mauve, lavender, and white following along.

Thomas Stevenson.

Woburn Place Gardens.

Calceolaria integrifolia. — This shrubby species of calceolaria is very useful for the embellishment of the conservatory during the autumn months, although for some reason or other it is not much known. It forms a freely-branched bushy specimen, clothed with rugose leaves, and bears a great profusion of golden-yellow blossoms. It is also a desirable kind for bedding, that is, where large plants such as are used in the case of Calceolaria Burbidgei, are employed. This last-named is also useful for flowering under glass during the autumn and winter. The pale-yellow-flowered C. amplexicaulis also, which is so much used for garden decoration, will, with greenhouse protection, continue to bloom well on into the autumn.—K.

OUTDOOR AUTUMN-SOWN SWEET PEAS.

The general practice with growers of sweet peas is to sow the seeds in autumn, and this is usually done during the last week in September, or first fortnight in October. This plan undoubtedly gives the best results, whether the peas are grown to give the best exhibition blooms, or to supply plenty of cut blooms for use at home. Cold frames are generally considered necessary to protect the young plants from injury by frost and rain during the winter months, but only on extremely heavy soils is this so, the best sweet peas being as hardy as the garden cabbage, if treated as hardy from the commencement of their existence.

Some, at least, of our market growers now sow their seeds thickly in loose soil in the same way as cabbages or other hardy plants are sown, and then transplant into their permanent quarters as soon as large enough; these plants stand the ordinary English winter without harm, and come into bloom from ten to fourteen days earlier than those sown in February in frames. This plan may be safely followed on all fairly light soils, or the seeds may be sown (if the ground is ready) directly into their permanent quarters.

We have now had three years' experience of this system, and find that it answers admirably, although, as our soil is so retentive of moisture, we take the precaution to protect the young plants from the winter rains; whether even this is necessary, is an open question, as we have seen them, after the protection has been removed in early spring, completely covered with snow for two or three days at one time without receiving the least injury, and in one instance the ground was frozen hard to a depth of three inches after the plants had begun to make their young spring growth.

We sow on ground which is not rich in nitrogen, but where it has been well managed and deeply worked the previous winter, and a crop taken off in summer, the top is lightly forked over, but no fresh manure is added, and it is allowed to lay at least a few days before sowing. The seeds are sown during the last week in September rather more thickly than is advisable for spring sowing; the seedlings appear in from three to four weeks, and the first thing to be done is to protect them from snails and slugs, for it seems that as soon as the first bit of green appears, every snail or slug within a hundred yards makes a "bee line" for it; perhaps at this time they are tired of the succulent lettuces, etc., and are longing for a change of diet, but, be this as it may, the fact remains that all through the winter these are the worst enemies of sweet peas, and precautions must be taken accordingly.

Soot is only a temporary protection, lasting only for three or four days, or even less, if a heavy rain should come. The best and most lasting protection that we have tried is "Phenol" (probably ordinary carbolic acid would answer just as well). We obtain sufficient perfectly dry coal ashes, coke breeze, or saw-dust to make a thin row on each side of the peas; then make a 50 per cent. solution of "Phenol" and water, and well moisten the ashes so that these become thoroughly impregnated with Phenol. Then place the treated ashes entirely round the plants, and a few inches from them. This protection will last from three to four weeks, when another application should be given; this material is perfectly harmless, and costs little.

In November we place small handlights over the rows in such a way that, while throwing off the rain, they neither obstruct the light or the free circulation of air. The latter is perhaps of more importance than may at first appear, for, naturally, the less protection the plants receive, the better chance will they have of passing through an excepionally hard frost, should one come.

Little else is done until the beginning of March, when the protection from rain is removed entirely, and the plants left to the mercies of, generally speaking, a mixture of all kinds of weather. They will probably present a very disappointing appearance at this time, compared with those that have had the protection of a frame, and the inexperienced might be inclined to "dig them in" as useless, but let him wait for two or three weeks until the spring sunshine and prolonged light have had time to make their influence felt, and he will change his mind. The sweet peas may not have quite as much green top early in the month, but they have the advantage over those in the frames in being thoroughly inured to the cold (a few more nights and days of which they have still to pass through), their roots, which have gone down into the soil from twelve to fifteen inches, will escape the disturbance and consequent injury which the others have to go through, and altogether will have laid a better foundation on which to build up the future flower-bearing growth.

The growths will now come from near or from under the surface of the soil, and these should, as soon as possible, be regulated to one or two to each plant. The seedlings will probably require thinning, as each one should have at least nine inches to itself. If the very best blooms are needed all lateral growths must be kept pinched out in the same way as we treat chrysanthemums.

When the sweet peas have started well into growth, we give a dressing of sulphate of potash at the rate of ½oz. to the square yard. This is repeated in three weeks' time, after which, when the plants commence to show flower, we give occasional dressings of nitrate of potash and phosphate of potash at the rate of ½oz. each to the square yard.

Treated thus, sweet peas produce plenty of "fours" during June and July, with stems up to 18in. long, and will continue to give good blooms right on into September—a full sixteen weeks. If there is any other hardy plant that will give such dainty and fragrant blooms in such quantities, and for so long a time, I should be glad to make its acquaintance.

R. B. Leach.

Woodhall Gardens, Dulwich.

PUSCHKINIA SCILLOIDES

Less familiar in gardens than either scilla or chionodoxa, yet in some ways suggestive of members of both these genera, Puschkinia scilloides appeals to every lover of hardy flowers. It reaches a height of some six inches, producing its bluish-white flowers in the upper part of the slender spikes. The striking features of the flowers is the stripe of blue line that passes down the centre of each petal, and is conspicuous enough to immediately arrest attention. In order to obtain the best results with the Puschkinia it should be planted in a well-drained spot in a mixture of sandy loam, peat, and leaf-soil and on a sunny slope of the rock garden or at the foot of a wall where the border is devoted to choice bulbs. Such a position ensures a thorough baking to the bulbs after they have bloomed, upon which their subsequent flower production largely depends. Heavy soil and damp positions in winter are fatal to the best results with this pretty spring-flowering bulb.—T. S.

SOWING SWEET PEAS.

I have tried many ways of raising sweet pea plants, and have sown seeds during every week between October 10 and the middle of April; but I find those sown about the middle of October are the best in nearly every instance. I prefer to sow the seeds singly in 3in. pots, but have had good results from seeds sown in boxes and in larger pots Plants raised in boxes, or in pots with more than one, should be potted singly into 3in. pots about the end of January, and great care is necessary not to break the roots during removal. Sweet peas sown in 3in. pots we do not disturb, but they are planted out in April from these pots.

I prefer maiden loam for sowing the seeds in, but have used old carnation and old chrysanthemum soil with fairly good results. For sweet peas that are to remain in 3in. pots for about six months, good fresh soil is essential. A few days before starting to sow, we mix up three parts loam, one part leaf-soil, and a half-part of sharp sand. In the bottom of each pot we place one crock and a little rough leaf-soil. Frames should be made ready, and an 8ft. by 6ft. frame will hold about 500 3in. pots. Therefore one can easily tell how many frames will be required.

Before starting to sow, all the hard-skinned seeds are chipped with a knife on the opposite side to the germ. We never chip lavender, blue, cream, or white varieties. These latter I prefer to sow in boxes or pots, put about a quarter of an inch of sand around the seeds, and a little soil on the top of the sand. Seeds of these are very apt to rot if treated in the same way as the other varieties. Fill the pots up to within a quarter of an inch of the top, make fairly firm, and press a seed in the centre of each, about a quarter of an inch deep. In the boxes sow the seeds about an inch apart. Place the pots or boxes into the frames at once, putting them closely together. If the weather is very wet the lights should be put on, but if fairly fine leave the lights off except in severe frosty weather.

If the weather is dry give water with a rose water-pot, but I prefer to let the rain do the watering if possible. A good grower will not allow his plants to become dry, and, if he can possibly help it, never allow them to be too wet. The happy medium is the thing to aim at from the day the seed is sown. If more than five degrees of frost occur, the lights are best on, but should not be closed for less than eight degrees of frost. I protect my plants in severe frosty weather, but five degrees of frost in the frames do not hurt them; at eight degrees close the lights, and if more than ten degrees occur protect with mats, and put something around the sides of the frames, so as to protect those nearest the sides. I do not like to see the soil frozen hard in the pots.

There are three things one must keep a sharp lookout for, and these are slugs, mice, and birds. The best remedy for slugs is to dust the seedlings with soot and lime every two or three days from the time the first seedling shows above the soil and strew some Vaporite or coal ashes around the frame. The only remedy against mice is to catch them; therefore do not wait until they have had a night or two among the seeds, and perhaps destroyed many of the choicest varieties; but place several traps in each frame the same day the pots of seeds are put in. If the birds start upon one plant, precautions must be taken against them at once. Black cotton run over them is the best remedy; or a very thin net may be used; but a heavy net will draw the plants up weakly.

The soil for potting seedlings raised in boxes or pots should be about the same as advised for sowing the single seeds in; but old chrysanthemum or carnation soil will do well. No crocks are needed in the pots, but just a little rough soil over the bottom is all that is necessary. Pot fairly firm, and put them back into frames, and do not let frost touch them for a week or two.

A. E. Usher.

Ranston Gardens, Blandford.

SWEET PEA MARKS TEY.

Flowers rose-maroon and bluish-mauve. Introduced by Messrs. Dobbie and Co.

(See page 746.)

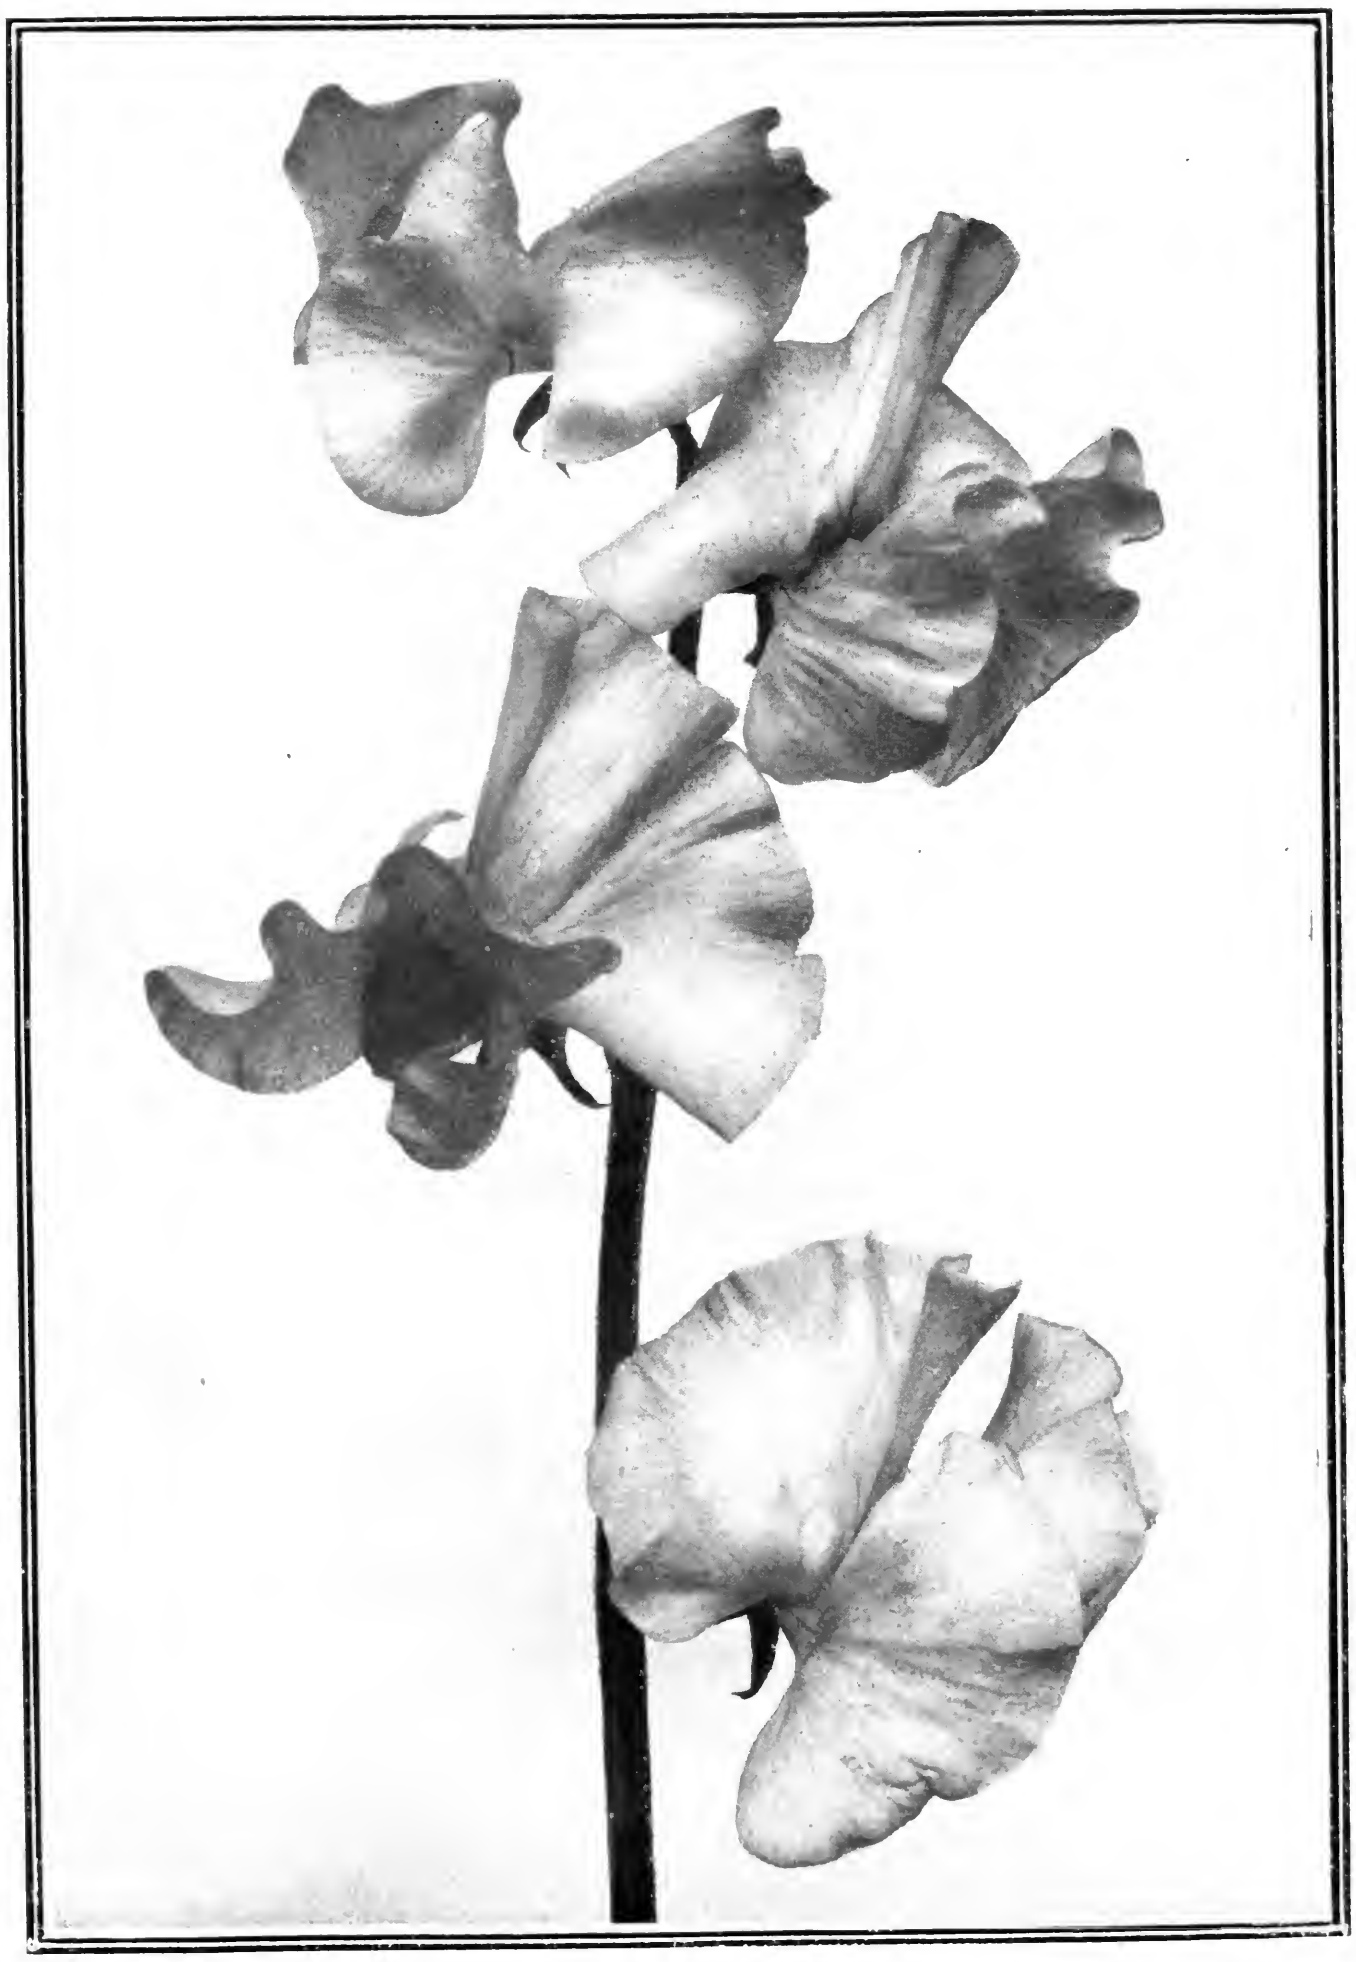
REGARD TO INDIVIDUALITY IN PRUNING.

"Pruning apple trees cannot be reduced to a formula. No two apple trees are alike. Each has individuality with respect to shape and habit of growth. Even the man who prunes with the greatest skill cannot accurately tell another man how to prune an apple tree."—Dr. J. C. Whitten, Prof. of Hort., Univ. of Missouri.

The practice of gardening has become so widespread during recent years that the majority of amateurs may probably be included under the term novices—at least, it seems that most people who speak to me on the subject are in the earlier stages of learning—and the result is that advice and instruction pour in upon them from all quarters, even the morning papers in most cases contributing their weekly quota. Most of it appears to be intended, as might be expected, for those who have not advanced very far in their knowledge of the craft, and doubtless this makes it acceptable to the greatest possible number. There is one respect, however, in which much of the instruction offered might go a little further to the advantage even of the beginner, and that is, by occasionally particularising instead of generalising. It is not enough to tell the beginner in fruit-growing to pinch or shorten the shoots of his dwarf apple trees in July, and further shorten them in the winter, for if he follows this advice with all his trees, he will treat some in quite a wrong way.

Study of Individual Trees.

The great universal rule in all pruning is to study a tree or shrub, and try to understand its nature better before touching it with the knife. It will do it much less harm to wait a year or so before being pruned than it will do to start cutting it before we know anything about it. Clematises form an interesting study in this connection, for while some flower only on the young growth of the current season, others only flower on the growth of the previous year, so that it would be obvious folly to give one general rule for pruning them irrespective of the species to which they belong. Chrysanthemums are another striking instance. If growers were told to take the crown buds in the middle of August, he would be given advice which was good in most cases, but in the remainder either impossible to follow, or the wrong course to adopt, if it could be carried out, the writer or speaker ignoring the fact that amongst a dozen varieties four or five might either not have crown buds to take in the middle of August, or, having them, they ought to have been taken a fortnight previously. It has even been suggested that lists should be made—catalogues would be the ideal place for them—showing the usual dates of the second breaks and the times for taking the crown buds, just as lists of fruit trees show the season and quality of the various fruits. The above will serve as illustrations of individuality, manifested as it is in the habits of growth and flowering in varieties of the same species, or in closely allied species, and the way the system of pruning—for taking the crown buds of chrysanthemums is a form of pruning—should be adapted to their peculiarities.



SWEET PEA LADY MILLER.

Flowers apricot and pink on a cream-coloured ground. (See page 746.)

Varying Characteristics.

These among some fruits are scarcely less than those of the chrysanthemum and the clematis, and to treat all alike will have little less harmful results in the one case than in the other. For instance, certain varieties of apple, such as Lady Sudeley, Worcester Pearmain, The Queen, Irish Peach, and Mr. Gladstone form fruit buds or some of the best of their fruit buds, at the tips of the young shoots, and some of the finest fruit is produced at these extremities. Obviously a universal system of shortening would mean the loss of some of the finest part of the crops. Some very strong-growing varieties, such as Bramley's Seedling, Beauty of Kent, Striped Beefing, and Blenheim Pippin, if grown as dwarf trees, should have their extension growths shortened as little as possible, because they naturally grow too strong for this form of tree, unless we can get them into good bearing early; while, on the contrary, such heavy bearers as Stirling Castle, Lane's Prince Albert, Seaton House, and Court Pendu Plat need to be pruned very hard from the beginning in order to restrict bearing somewhat and encourage freedom of growth. In other words, each variety should be pruned in such a way that we may lessen the power of their defects, and help them to take on good habits. With pears the differences of habit are quite as distinct as with apples, perhaps even more so, as there are several varieties the trees of which we are able to name even when the leaves are off, and many which we can identify from their leaves and manner of growth alone.

Variability of Trees.

All this is, however, subject to one important qualification, namely, that trees of the same variety vary considerably among themselves according to the stock upon which they are worked and the vigour of the original bud or scion from which the tree has grown. Here we have always an uncertain quantity to deal with, for two trees of the same variety may be of such different constitutions that whereas one may need to have its growth repressed to encourage fruitfulness, the other may need to be fed up to get it to make sufficient growth. If the beginner says it is hopeless to think of learning to prune any fruit tree, we must answer him by referring to the basic principle of the pruning of all trees. Study each tree as an individual, and treat it according to its needs, this presupposing, of course, an acquaintance with the general principles which underly all pruning.

Alger Pitts

SOME DEBATABLE TOPICS.

Why are Apples Failing to Mature?

Apples are none too plentiful this year in many places, and in more than one plantation I have noticed the same disappointing trouble as was so prevalent last season. To state a case in point, I was in a plantation the other day which contains a number of healthy and well-grown trees of Lord Grosvenor apple, that are carrying a heavy crop of fruit, but on every tree, and almost without exception, the apples are scrubby little specimens about the size of walnuts, ill-shapen, and wrinkled about the eye. I am told that before the flowers opened the trees were sprayed with nicotine solution for the apple-sucker, which was obviously effective, as no one could wish for a better crop so far as numbers are concerned. The question open to debate then is, What is the cause of the fruits failing to come to maturity?

It is necessary to explain that the trees in question, in common with most others by the way, were the victims earlier in the season of a severe attack of Apple Aphis, and though attempts were made to cope with it by means of spraying, these were only partially successful owing to delay in getting at the work until the pests were safe inside the curled-up leaves. Is the unsatisfactory behaviour of the apples now due to the effects of that attack of aphis? This is the point under debate, and I should like to have the views of other readers of The Gardeners' Magazine on the subject. It has been suggested that the cause of the apples failing to swell properly is due to something being wrong with the fertilisation at the time of setting, but I rather favour the theory of aphis crippling growth and sucking the sap out of the leaves at a critical period. Last year I saw a whole crop of Bramley's Seedling affected in the same way, and in numerous plantations and orchards again this season the trouble is widespread. Is aphis the initial cause of it? If so, we shall have to look upon this pest as being amongst the most injurious to apple crops.

Head Grafting Old Apple Trees.

When is an apple tree too old to be head grafted with another variety? Don't all speak at once please, because it is a subject that wants thinking about. I do not fear contradiction when I say that Bramley's Seedling has no superior as a variety to graft on old trees, and it is claimed for it that it has the power of imparting some of its own natural vigour to the stock, and thereby rejuvenates it, but this is hardly the case, even with Bramley's, if the stock is too old. I could point out now a score or more of orchard trees that have been grafted two or three years, and up to a few months ago they looked very promising. This summer has apparently been too much for them, however, for big pieces of bark on the stems have died and peeled off, and the foliage on the Bramley heads has wilted and fallen. In short, some of the trees are dead, others are dying, and much time and labour are thrown away. Experience of the above kind raises a doubt as to the wisdom of head grafting trees that are getting on in years, but just when they are too old is the point open to debate.

Judges at the Shrewsbury Show.

Why do they not change their judges a bit more frequently at the world-famed Shrewsbury Show? No doubt the Shrewsbury Committee could answer this question better than anybody, and the answer might be that they have got good men and true for the work and could not improve upon them. I do not dispute the point at all, for I happen to know a good many of them, and can testify to their abilities, but the proverb that there are as good fish left in the sea as those that are drawn out applies also to show judges, and in more ways than one changes, so far as the adjudicators of prizes are concerned, are good. I do not mean to say that the present set of more or less stock judges should be put aside altogether, but it would be in no way uncomplimentary to them if they stood out for a year or two in favour of other experts, and then came in again later on. It would be interesting to know, by the way, how many years some of the Shrewsbury judges have officiated, and, though it is complimentary to them to be asked again and again, there is a good deal to be said in favour of changes.

Deep Culture and Prize Onions.

It goes without saying that size is the ruling factor in exhibition onions, and, no matter what other qualities your bulbs may possess, you stand very little chance unless you have them of large size. It has come to be a generally-accepted theory that trenching the ground two or three feet deep is an essential operation in the cultivation of large onions, but I am beginning to have my doubts as to whether there is as much in this theory as we have been led to believe. I should like to hear what others have to say about it, but a well-known exhibitor and prize-winner informed me the other day that he has obtained bigger onions this year than he has had before, and has grown them on well-dug and manured ground that was trenched the year before, but not this season for the onions. I would suggest treating the matter experimentally by trenching half a bed in the orthodox manner, and digging the other deeply, but without disturbing the subsoil. We know that onions like a firm soil, and perhaps it is that this deep trenching process loosens it rather too much.

Why not Natural Effects in Public Parks?

Why do the officials who are responsible for the bedding arrangements in public parks not pay a little more attention to natural effect, instead of surfeiting the eye with glaring masses of flowers whichever way you look? A short time ago I strolled into a pleasant little public park at a popular West of England seaside holiday resort, and a feature of this park is broad stretches of turf, with deciduous foliage trees dotted about on it. These, with the grass growing up to the stems, would have been ornamental and quite in place, but instead of this a circular bed some eight feet in diameter had been made round each of them, and the rings were edged with artificial-looking stones. What was the result? Simply that fine-looking, ornamental trees were seen growing, as it were, out of the centres of round, stone-edged beds, planted with scarlet pelargoniums and yellow calceolarias. Could anything be more absurd? To my mind public park gardening should be educational, with an intent to show people where and how to put flowers where they are in and not out of place, not to put them anywhere and anyhow purely for the sake of having them. H.

EUCRYPHIA CORDIFOLIA.

Among the numerous choice shrubs contained in the extremely interesting collection made by Mr. T. B. Bolitho in his famous garden at Trewidden, near Penzance, is a fine example of this South American species, which, at the present time, early September, is in full flower. It is less well known than the allied species, E. pinnatifolia, of which, by the way, perhaps the best specimen in the country is growing at Trewidden, and it is said to have flowered for the first time out of doors in this country, in the Coombe Wood nursery of Messrs. J. Veitch and Sons, in 1897. Good examples are rare, and the species appears to be unknown in most gardens in the south-west, although it is essentially a plant for the climatic conditions which prevail in Devonshire, Cornwall, South Wales, and Ireland.

E. cordifolia is a native of Chili and Chiloe, where it forms a tree in the forests. The leaves are evergreen, broadly oblong, thick in texture, two to three inches long, and one to one and three-quarters of an inch wide, very downy on the under-surface, especially on the veins and petioles, and clothed with short, silky hairs on the upper surface. The margins are more or less crenate. As in the case with the under-surface of the leaves, the bark of the younger wood is extremely downy. The flowers appear singly from the leaf axils, each one being about two inches across, with white petals, and a central mass of brownish stamens. Each shoot bears seven or eight, or more, flowers from near the apex, and a very beautiful picture is formed when the blossoms are at their best. It is apparently a difficult plant to propagate by any other method than seeds, and like the better-known species, the most satisfactory plants are those raised from them. It thrives in loamy soil, but is not averse to a little peat being placed about the roots at planting time. In those gardens in the south-west where it does not already exist it ought certainly to be given a position amongst the choicest subjects. A figure and description of the shrub is given in the "Botanical Magazine," t. 8209.

W. D.

A Handsome Poplar (Populus trichocarpa).—Our attention has recently been called to a very handsome poplar, of which two specimens occur among the trees forming the roadside avenues, consisting mainly of limes and planes, at East Acton. The tree belongs to an entirely different species from the ordinary slender poplar, representing the popular type of the genus. It has a similar habit to the lime, and bears large leaves, some six to eight inches long without the stalk, of an acutely-pointed pear-shape, attached by the semi-circular base to a rather long stalk, and with the underside of a silvery white. They are somewhat pendulous, and in a breeze display their silvery backs very freely and prettily. The tree is a by no means common one, but might well be recommended for more extensive use for suburban avenues, as its foliage appears very early in the spring, and it forms a capital foil here and there amongst the commoner trees utilised for that purpose.—C. T. D.

STONE-SPLITTING IN PEACHES AND NECTARINES.

This year I have met with rather more than the usual number of cases of stone-splitting among peaches and nectarines, and think it might not be amiss to draw attention to the causes of, and remedies for, the evil, now that we are on the eve of the planting season, in order that provision may be made to avoid such unhappy results in the future.

The evil is due to one, or both, of two causes, viz., an unsuitable border and fluctuations of temperature at certain periods of fruit development. The border may be regarded as the chief source of stone splitting, as its condition, both chemically and physically, has the greatest influence on the vitality of the tree, but even with this as it should be, unfortunate results of stone splitting will follow rapid rises of temperature at the time the stones are forming.

Peaches and nectarines love good drainage in the border in which they grow, and resent anything approaching a clammy and sour root-run; it is therefore imperative that their root medium should be well aired and sweet. All stone fruits must have abundance of lime in the soil, and none need more than peaches and nectarines, and on this account an ample supply should be provided. Phosphates and potash are also indispensable fruit-producing food constituents of a soil for peaches and nectarines.

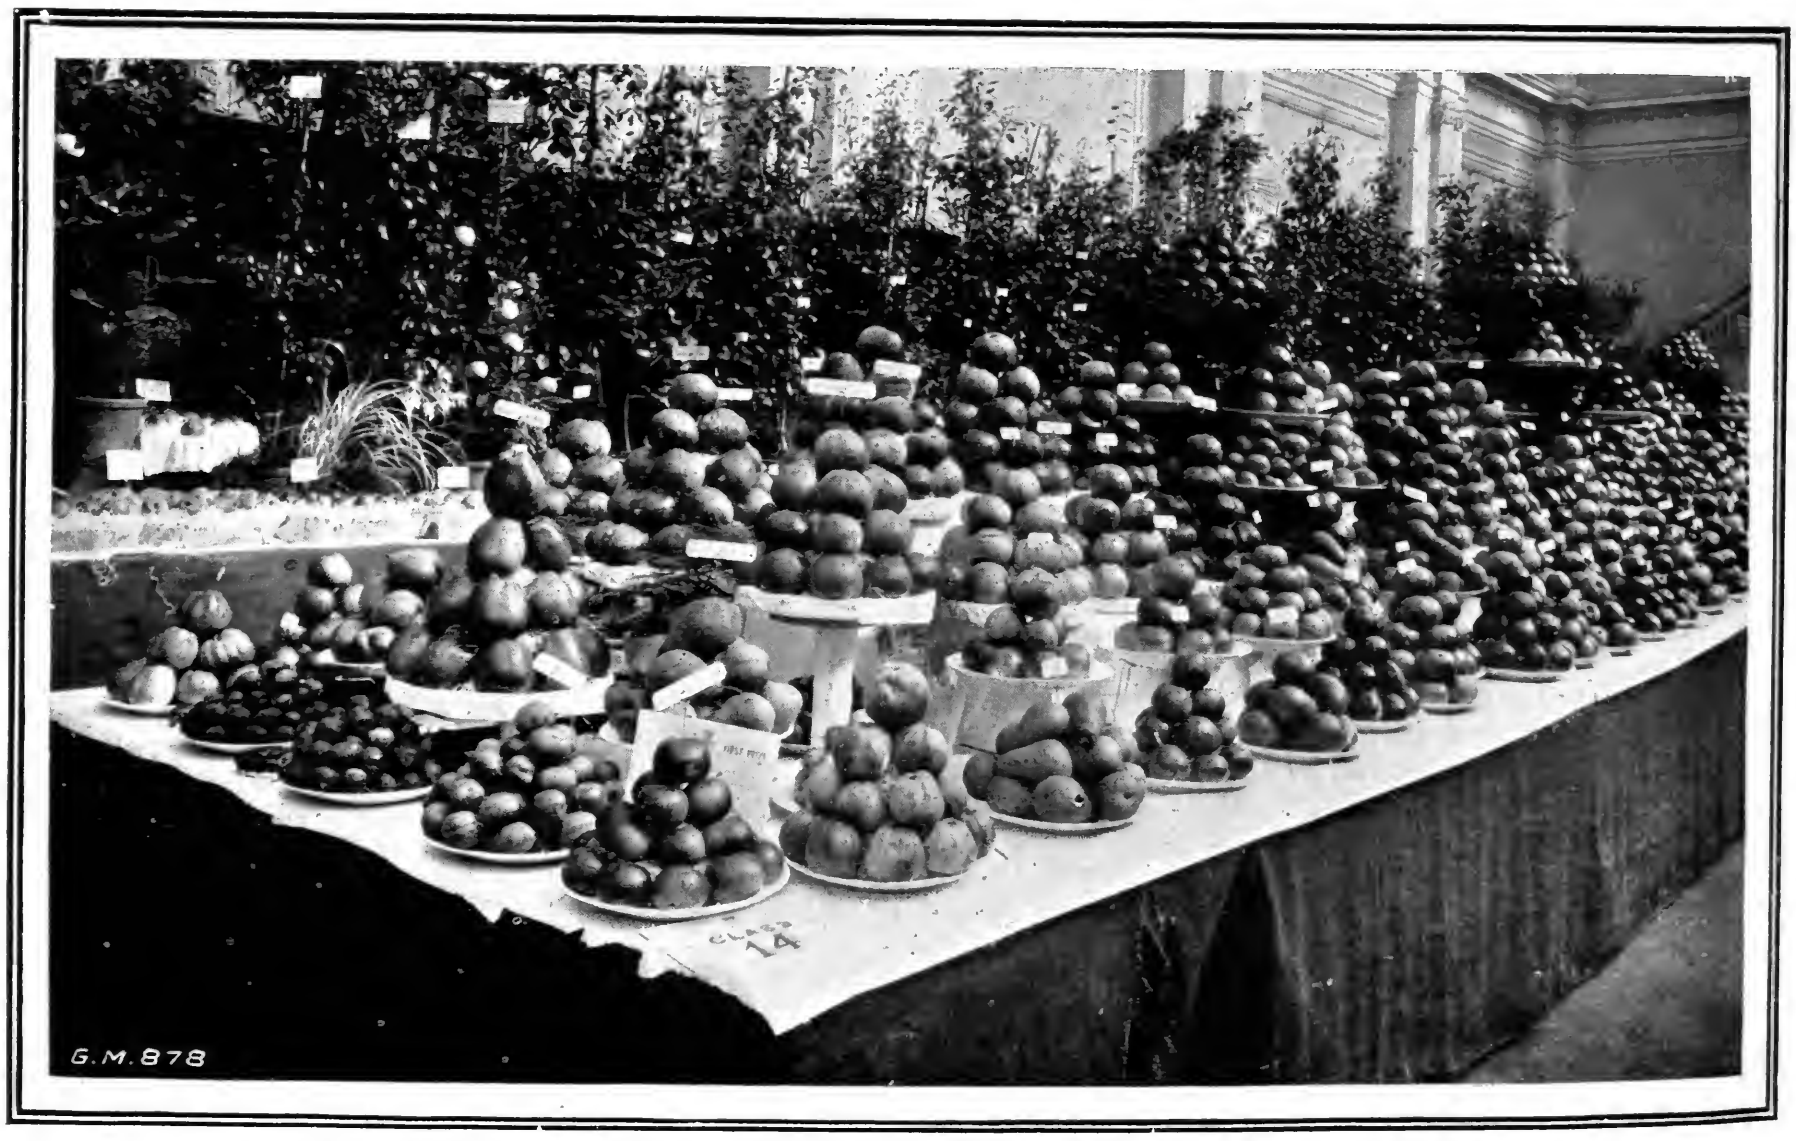
As the aim in cultivating peaches and nectarines is to produce large finely-flavoured fruits, every care should be taken to provide the trees with the needful supply of food constituents—phosphates, lime, potash—in an available form, and to regulate the quantity of nitrogenous manures in accordance with their needs. In the case of stone fruits lime is specially valuable in composts, and the larger the stones the greater the demand for lime. Peaches, nectarines, and apricots have larger stones than cherries, damsons, and the majority of plums. Consequently the former should be afforded a larger supply than the latter. Soils rich in phosphates, potash, and lime, free from acidity and excessive organic matter, give little trouble in stone-splitting, when care is taken at the beginning of the stoning period to avoid rapid changes of temperature. It is when these plant foods, especially lime, are lacking, that stone splitting is most troublesome, as the walls of the stones are weak and unable to resist the pressure of the pulpy tissues within them when a sudden expansion is occasioned by a rise of temperature.

When new borders are contemplated, I would advise making them three and a half feet deep, with a slope to the sun. Along the front of this a main drain, with others at right angles about 10ft. apart, should be run across the border, and the remainder of the bottom filled with brickbats, stones, clinker, or any other porous material, to the depth of one foot. On the top of this should be placed two and a half feet of a compost in the following proportions: Five cartloads of yellow, turfy loam chopped into pieces about three inches square; one cartload of old plaster or lime rubble, screened; three hundredweight of bonemeal, and a quarter-hundredweight of sulphate of potash. The whole must be well mixed and made moderately firm. No organic manure should be employed.

If a border of this kind is made early in the autumn it will be fairly warm, but if made in winter it becomes cold. In the latter case water at a temperature of about 90 degrees should be used to moisten it when the trees are to be started into growth. In such borders stone splitting will be little known if proper attention is paid to ventilating during the early, critical, stoning period. With early forced trees it is sometimes difficult to keep down the temperature and prevent cold winds reaching the tender foliage. If this can be accomplished, much will have been done to prevent stone-splitting. During the stoning period a lower rather than a high temperature, with a free circulation of air in the structure, should be aimed at. By this means the thin wall of the stones will have time to thicken and harden without undue pressure from within, and the likelihood of splitting be rendered remote.

Worn-out borders may be partly renewed with the compost advised, and where this is not convenient, a liberal quantity of bonemeal should be worked in, and lime and potash applied to the surface. Sulphate of potash applied in this way should not exceed one and a-half ounces to the square yard for one dressing. The dressings can be repeated throughout the growing season. Nitrogenous manures should only be employed to assist the trees to finish a rather heavy crop, and therefore should not be applied until the second swelling is taking place.

HIBERNIA.



AN ATTRACTIVE TRADE COLLECTION OF FRUIT GROWN IN THE OPEN.
Exhibited at the R.H.S. Fruit Show by Messrs. H. Cannell and Sons, who were awarded the Gold Medal. (See page 754.)

Rhubarb.—For very early forcing purposes it is absolutely necessary to have crowns which have been properly prepared and given a short season of rest, and suitable early varieties. It is advisable to lift the crowns at the earliest opportunity, leaving them fully exposed to the weather; and if they have a few frosts on them they invariably start into growth much quicker and stronger. When placed in heat the light must be thoroughly excluded, and a strong, moist heat given.—W. MESSENGER.

AMONG THE ALPINE FLOWERS.

O vagrant, happy rover!
Gatherer of treasures rare!
Never did truest lover
A heart so happy bear.

Such almost might the poet have written of the lover of alpine flowers. He is a "vagrant, happy rover," not satisfied with devoting his affections to a few flowers, but delighting himself with the enjoyment of the many treasures which the alpine flora present to his admiring gaze. Yet, though he may roam from flower to flower, he is no less constant in his affection; for it is strange, but true, that hardly anyone who has ever really become interested in the alpine flowers ever loses that love for these winsome plants, and forsakes them for other flowers. Even in autumn, as we wander through the garden we see some treasures, though, of course, the heyday of the alpines is over for the season. Yet in this bountiful year—for bountiful to these plants it has been, and one hardly remembers a better year, as a whole—one is full of gladness as one studies the flowers.

Hypericum coris.

Here, for example, is that dainty little St. John's wort, Hypericum coris, happy-looking and cheering, on its little flat bit of the rock garden. Its small, open starry, bright yellow flowers have all the brightness and beauty of the race, yet look infinitely more refined than many of the sister flowers. The little tuft of heath-like foliage, gracefully set along the fragile-looking branches, or rather stems, each with its refined-looking flowers, completes a picture of really fascinating appearance. One of our keenest critics calls it "that sweet-tempered treasure of golden beauty and golden value," and nobody can well cavil at the description, save it be those who have found that Hypericum coris is not always so "sweet-tempered," as they would like. But even the most placid will become soured by want of consideration, and we have before now seen this St. John's wort unhappy and even sulky when in blazing sun and away from the coolness it seems to appreciate. It has never done so well with the writer as in semi-shade, and there it has stood the hardest winters within many years unscathed, and has flowered with great freedom. There are more showy St. John's worts (and many of them, too), but it is doubtful if any of them is more delightful than that little coris-leaved one which is the subject of this note. Beside the golden, wide-spread flowers of H. fragile, or the softer-tinted blossoms of H. reptans, it may appear less charming, but when we come to know it, we admire it with ever-increasing admiration.

Gentiana septemfida.

Gentians are of wondrous beauty, as a whole, though there are flowers among them which should be rigorously excluded from the garden. They are the pariahs of the race, and justly banned from the company of their own kind, unless, it may be, to act as foils to the grace of their kinswomen. But no one can well say that Gentiana septemfida has not earned its right of admission into the rock gardens of all. It is not so dainty as its sister, G. verna, nor has it the compact beauty of its forerunner, our lovely gentianella, yet it has for us many charms as we look at a good plant on a level place, not too high up, where we can look down on its glossy green leaves and its wondrously fine blue flowers. Give it a cool place, and in July and August you are charmed with its glorious flowers. We call them "azure," but feel convinced that the word has not yet been coined which will give full value to that glorious hue of this easily-grown gentian.

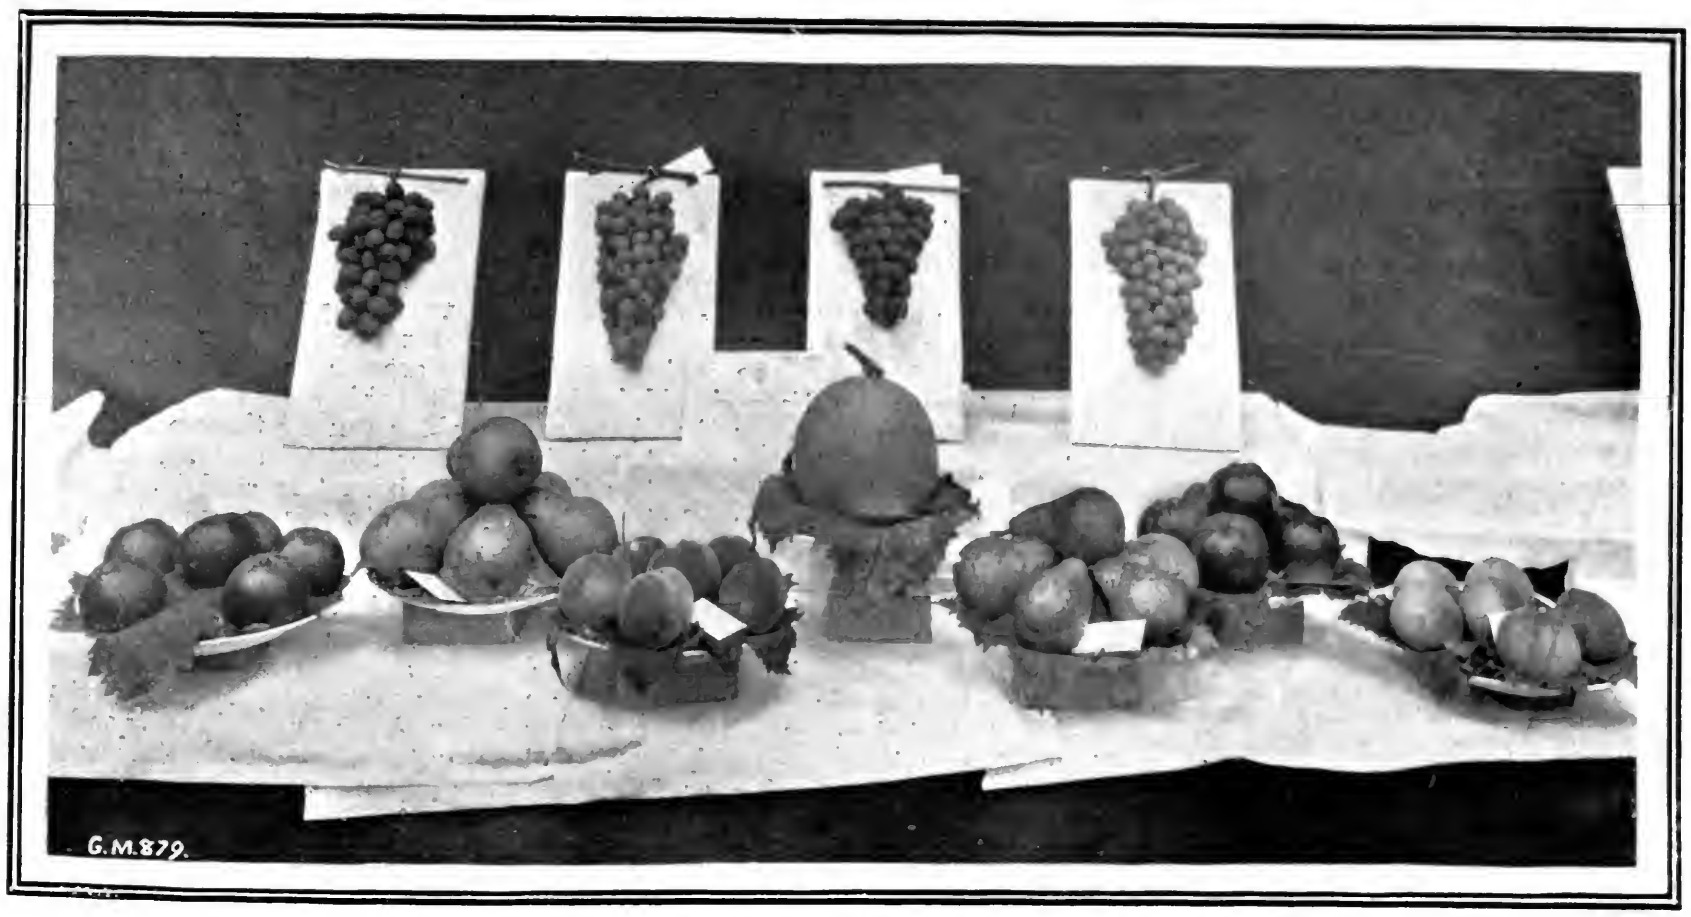
Androsace lanuginosa.

It is some years since I mentioned this grand androsace in these notes, but it is not because of any want of admiration for its charming ways, but rather because of an objection to referring to even the most lovely flowers too many times. Yet it cannot be over-praised. At least, so does one think as one sees it trailing over the stones, with its lovely satiny leaves and its exquisite flowers. Of rare value is it, too, seeing that there are none too many of our alpines which will keep up so long a period of bloom. It began in June this year; in July it was delightful; in August it was one of the most prized of our flowers; and from now until frost comes and despoils our gardens of their beauty it will be the "observed of observers," and the admiration of all. Were one confined to one Androsace alone it would be A. lanuginosa, which would be chosen as the most generally delightful and of the highest value. What more can one say of a flower such as this?

Campanula rotundifolia alpina.

There are two bellflowers which are rivals for the honour of being the finest of the lovely harebells, which come in our gardens in July, and generally last into August should the weather be cool, and not giving us showers or wet days followed by brilliant sun, than which nothing sooner shortens the period of beauty of the varieties of Campanula rotundifolia. These rivals are the true C. r. Hosti and C. r. alpina. One's allegiance may be claimed by both, and it is not easy to pay obeisance to one, and to say that this is the queen of the round-leaved harebells. There are good masses of both in my garden, and when they are in full bloom it is almost impossible to say which is the more beautiful. Both have big bells of deepest blue, and they give exquisite groups of graceful growth and lovely colouring. Of Campanula rotundifolia alpina, often sold as the true C. alpina, but a much more satisfactory plant, it is enough to say that it is a gem, with its dainty, rather hairy foliage and its fine deep blue bells in endless profusion, drooping gracefully from the stout, yet elegant, stems. Perched on the rock garden a little above the level of the eye, a group is exquisite indeed.

S. Arnott.



FIRST PRIZE COLLECTION OF NINE DISHES OF DESSERT FRUIT.
Exhibited by Mr. S. Barker at the R.H.S. Fruit Show. (See page 753.)

Cytisus Andreanus prostratus.—The plants of this cytisus shown grafted standard high are most attractive, but it promises in a general way to be most valuable when allowed to grow naturally as a creeping shrub, in which way it will soon cover a considerable space. For the foreground of shrubberies, or for the bolder arrangements of rockwork, it should be very desirable. The flowers have the colour of the typical Cytisus Andreanus, and consequently produce a bright effect.—S. W.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

CYPRIPEDIUMS. — Many of the late autumn and winter-flowering cypripediums are producing their flower scapes. The earliest to bloom are C. Charlesworthi, C. Fairieanum, and the hybrids derived from the inter-crossing of these species with other kinds. The flower scapes of these will need supporting with neat stakes. These should be put in the desired position before the flowers become far advanced. If this is done the flowers will be displayed to the best advantage. If the flowers are permitted to become expanded before staking is done, it is difficult to fix them in the desired position. Many of the specimens of the winter-flowering lady's slippers, such as C. insigne and C. Leeanum, and other vigorous-growing varieties that have their pots matted with roots, may have occasional applications of weak liquid manure, made with cow manure, as soon as the flower buds make their appearance. This will assist root-bound plants in the development of their flowers. In the case of plants that have ample room, care must be observed to see that they are not allowed to become dry. Often at this season, when artificial heat causes a more rapid evaporation, the compost dries much more rapidly than during the summer season. It is a good plan to dip the pots occasionally, instead of watering; this will ensure a thorough wetting of the roots, which are at the bottom of the pots. As the leaves of trees in the open are falling it is necessary to carefully guard the plants from attacks of black thrips. These usually work on the under sides of the leaves, where they also deposit their larvæ. This is indicated by miniature black spots, which immediately on being observed, should be carefully sponged off. If this is not done, the plant will be injured, and the pest may spread over the whole house. Sometimes thrips also attack the flower scapes, but regularly spraying with some safe insecticide will keep all exposed parts free, and it is for this reason I have referred to the desirability of examining the lower sides of the leaves.

REPOTTING CYPRIPEDIUMS.—The potting of any of the summer-flowering kinds may now have attention. Practically all the species and varieties belonging to the tessellated-leaved section do well in a compost of equal parts fibrous peat and sphagnum moss with sufficient broken crock, charcoal, and sand added to render the compost porous. Where loam is used it should be carefully picked and the fibre portions only used. See that the pots used are clean and well drained, and the potting compost should be made moderately firm about the base of the plants. The seedling cypripediums that have not already received attention for repotting purposes; that is to say, those that have not reached the flowering stage, should be attended to without delay. It will be found that young cypripediums make more rapid progress during the next few weeks than is the case at any other season of the year.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CLIMBING PLANTS IN THE CONSERVATORY.—Before the winter sets in it will be necessary to give those plants growing over the roof a thorough overhauling. In some cases pruning or thinning out can be done now, so that plants growing beneath them may receive as much light as possible. Such strong-growing plants as cobæas, tacsonias, and passifloras may be very severely dealt with now, as they make abundance of growth during the summer months. Bougainvillias may have all the old flowering growths cut hard back. Cut out all useless shoots from climbing roses, as these are often spoilt by being overcrowded with weak, useless spray. Before filling the house with plants give the glass, both inside and out, a good cleaning, and remove all temporary shading.

CAMPANULA PYRAMIDALIS.—Give the young plants another shift if they are sufficiently well rooted. Next season's flowering plants may also be shifted into their flowering pots if they are ready. They may then be plunged in ashes in a cold frame. Supply water with care through the autumn and winter months, and place the lights on the frames during very wet weather. This campanula will not stand coddling, therefore give it abundance of fresh air whenever the weather will allow, removing the lights entirely on favourable occasions.

AZALEAS.—Indian azaleas must now be placed indoors, giving them a house where they may be kept as cool as possible until they are required for forcing. The shelter of a vinery or peach house will be suitable if other convenience is not available. Before putting the plants indoors lay them on their sides and thoroughly syringe them with a strong solution of soft soap and sulphur. Pot up Azalea mollis as soon as they arrive from the nursery, using a compost of loam, peat, leaf-soil, and coarse sand, and plunge the pots in ashes out of doors.

VIOLETS. — If these are not already planted in frames, no time should be lost in dealing with them. After they have recovered from the shift they must not in any way be coddled or failure is bound to ensue. Let the lights remain off altogether until severe frost is imminent. The double kinds may be grown successfully in pots, and are most useful when well grown for placing about the dwelling; six-inch or seven-inch pots will usually be found large enough, and a compost of loam, leaf-soil, and a little coarse sand will form a suitable rooting medium. Place them in a cold frame, and keep rather close for a day or two, then gradually inure them to full exposure until the time arrives to place them indoors. During the winter months a position quite near the glass in a cool house will be necessary, using fire heat as little as possible. Special attention must be devoted to the removal of dead flowers and leaves, and in supplying water to the roots be careful not to wet the foliage. A great many flowers are often lost through carelessness in this matter. —E. Harriss, Lockinge Park Gardens.

HARDY FRUITS.

PLANTING FRUIT TREES is now a matter for careful consideration, and, although rather early yet to lift the trees, it is well to settle what amount of planting is to be done, and make every preparation. A selection of the most useful kinds should be made, and the order sent to the nurseryman at once, as most of the orders are sent out in rotation. In preference to forming large collections, plant a number of trees of the most dependable varieties, which will keep up a long supply of both dessert and kitchen apples. There are many good kinds to select from, and we find for dessert amongst the best here are Beauty of Bath, Irish Peach, Devonshire Quarrenden, Lady Sudeley, Worcester Pearmain, King of the Pippins, Cox's Orange Pippin, Ellison's Orange, Scarlet Nonpariel, Kerry Pippin, Ribston Pippin, James Grieve, Blenheim Pippin, Duke of Devonshire, and May Queen.

COOKING APPLES.—The best with us are Lord Derby, Ecklinville Seedling, Golden Noble, Warner's King, Loddington Seedling, Tower of Glamis, Bramley's Seedling, Old Round Winter Nonsuch, Newton Wonder and Byford Wonder; but those who intend to plant on a large scale for market purposes will do well to pay a visit to some good, well-known fruit grower, ascertain the most useful kinds for the purpose and the district, and obtain good, healthy trees in preference to cheap stuff; a little extra cost for good trees is by far the best outlay.

AUTUMN RASPBERRIES.—See that the stools are thoroughly moist, so that the fruits may swell to a good size. Autumn fruiting raspberries should, after the dry season, crop freely; gather the berries at intervals when ripe, as they quickly rot in damp weather if allowed to remain hanging on the canes.

FRUIT GATHERING.—Attend carefully and regularly to this work, gathering the different varieties as they become fit. Although the crops this year are in some instances heavy, and owing to the dryness of the soil the apples are dropping before they are really fit, those that will hang should remain till the very last, or they will not keep, but shrivel and soon be of no value. Watch the nuts carefully, for mice and rats quickly strip whole bushes if not checked, and before one is aware that they are at work. Filberts should be first gathered and used, and the cobs as soon as they are ready. —H. Markham, Wrotham Park Gardens.

THE KITCHEN GARDEN.

SEAKALE.—The plants prepared for forcing should be stripped of dead leaves, as they can easily be removed after the first spell of frost. In order to obtain very early seakale the crowns should be dug up fully a fortnight previous to placing them in heat, taking care of the young roots or "thongs" which may be cut off the proper length, sorted into different sizes, and placed in boxes of light soil in readiness for planting in the spring. For successional batches lift the crowns in sand or ashes under a north wall, taking them out as required. To start seakale during the present month requires a strong bottom and top heat. Crowns which have been "frosted" a time or two always start into growth much quicker than those which have not been subjected to frost.

GLOBE ARTICHOKES.—The old plants should have some protecting material placed about them before sharp frosts occur; clean coal ashes is one of the best materials for the purpose. Where the stock requires replenishing, now is a good time to secure good, strong offsets. These should be potted up and placed in a cold frame for protection during the winter months. Admit plenty of air during suitable weather to ensure stout, sturdy growth; if all goes well they will be satisfactory plants for planting out in April or May, and should yield the first year.

ENDIVE.—Select and tie up the best developed plants in sufficient quantity to meet the demand, doing this when they are dry. Frost must be guarded against, as the tender inner leaves are readily injured by a few degrees of frost. Do not tie them too tightly, but merely collect the outer leaves and secure them with a strip or two of raffia, folding them loosely over the heart. In ten days to a fortnight afterwards the plants will be fit for use. Successional batches should be similarly treated. If a cold frame is available this may be placed over the plants where they stand, and mats should be used to exclude the light. Endive, when in a half-grown stage, may be dug up with a good ball of earth attached, and potted in frames for late use. Fully-developed plants may be lifted and placed thickly together in a mushroom house where they will blanch quickly and satisfactorily.

LETTUCE.—As there is nearly always a demand for lettuce, strong plants of various ages and sizes should be lifted and planted in cold frames. Ample ventilation should be afforded, keeping the leaves as dry as possible. Young plants from the later sowings will now be ready for transplanting to frames or cold pits. Lettuces may be sown in a quite young state if seeds are sown thickly in boxes or beds of soil in a temperature of 60 degrees.—W. Messenger, Waverton Park Gardens.

THERE IS A GREAT . . . SCARCITY of

ARCHANGEL MATS.

This condition of affairs was anticipated by Messrs. WOOD & SON, who

NOW HOLD HUGE STOCKS.

Order Now, and have Mats by you against Frosty Nights.

Best full-sized 9 ft. by 4 ft. 6 in. heavy weight 5 lbs. **ARCHANGELS, 16/6** per doz., carr. paid. Orders executed same day.

Send for full particulars of . . . . . **"DARJEELING" MATS** — **Last Six Times Longer than Archangels.**

CATCH THE MOTH NOW BEFORE SHE "LAYS THE DAMAGING EGG"

in your Fruit Trees by applying now Messrs. WOOD & SON'S

FRUIT TREE BANDS and GREASE.

ROYAL HORTICULTURAL SOCIETY'S SHOW
OF BRITISH-GROWN FRUITS.

Notwithstanding the rumours of poor crops there was a wonderful exhibition of fruit at the Royal Horticultural Hall, Westminster, on Thursday and Friday, September 25 and 26. The date was a rather earlier one, the council of the R.H.S. fixing it thus so that earlier ripening fruits might be shown. There was something lacking in colour, and pears were not so numerous as usual; but apples were remarkably fine all through, and a great contrast to the examples seen at the earlier fruit shows. Grapes were good and largely shown, and orchard-house fruits were a revelation.

On the whole the competition was close, especially so in the traders' classes, where there were some notably good examples of high culture and pleasing arrangement.

A FINE TRADE COLLECTION OF FRUIT GROWN IN THE OPEN.
Exhibited at the R.H.S. Fruit Show by Messrs. G. Bunyard and Co., Lim., who were awarded the Silver-gilt Hogg Medal.
(See page 754.)

At the judges' luncheon Sir Harry J. Veitch presided, and Mr. A. H. Pearson and Mr. E. Beckett responded to "The Judges." Sir Harry Veitch was heartily thanked for presiding, his health being ably proposed by the Rev. W. Wilks.

We venture to again suggest that the council might do a little to make this autumn show a more pleasing spectacle. The use of a few palms, bamboos, etc., behind the grape classes and down the tables where the single-dish classes are staged would improve matters considerably. On this occasion the left half of the hall presented a very flat and uninteresting appearance as viewed from the entrance.

CHOICE DESSERT FRUITS.

In the leading class for nine dishes of ripe dessert fruits, six kinds at least to be shown, there were three competitors, and the premier award fell to Mr. S. Barker, gardener to the Duke of Newcastle, Clumber, Worksop, for medium-sized but finely-berried bunches of Madresfield Court and Muscat of Alexandria grapes, Emerald Gem melon, Cox's Orange Pippin and King of Tompkins County apples, Durondeau and fine Pitmaston Duchess pears, and Barrington peaches. Second prize was awarded to Mr. G. Mullins, gardener to Lady Henry Somerset, Eastnor Castle Gardens, Ledbury, whose Rival apples and Marguerite Marrillat pears were fine, and his clusters of Black Hamburgh grapes very heavy. Mr. G. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, third, with fine dishes of Princess of Wales and Golden Eagle peaches, etc.

The class for a collection of six dishes of ripe dessert fruit brought out five competitors, and the silver cup and £3 as first prize was here won by Mr. J. Shelton, gardener to Lord Hillingdon, The Wilderness, Sevenoaks, with grand bunches of Muscat Hamburgh and Muscat of Alexandria grapes in good condition, a seedling melon, Negro Largo figs, Cox's Orange Pippin apples, and Lady Palmerston peaches. Mr. W. H. Cooke, gardener to Lord Belper, Kingston Hall, Derby, was a very close second with a handsome exhibit, in which Gros Colmar grapes, Cox's Orange Pippin apples, and Sea Eagle peaches were very fine. Mr. T. Pateman, gardener to C. A. Cain, Esq., J.P., Welwyn, third with an excellent collection.

GRAPE CLASSES.

Three competitors came forward in the class for six varieties of grapes, two bunches of each, and first prize was won by Mr. S. Barker, Clumber Gardens, who staged enormous bunches of Gros Guillaume, good Buckland Sweetwater, Muscat of Alexandria, Black Hamburgh, Gros Colmar, and Madresfield Court. Second prize was awarded to Mr. J. H. Goodacre, whose best bunches were of Madresfield Court and Golden Queen. Mr. E. C. Wickens, gardener to C. Bayer, Esq., Tewkesbury Lodge, Forest Hill, came third with large, but, in many cases, rather loose bunches.

In the Black Hamburgh grape class there were five entries, and the best of these was shown by Mr. J. Shelton, who had very solid, large-berried clusters; Mr. G. Mullins second, and Mr. S. Barker third. Three competitors showed Mrs. Pince, and Mr. G. Richardson, gardener to H. St. Maur, Esq., Newton Abbot, let with long, well-coloured clusters; Mr. Mullins second. Mr. Mullins scored for Alicante with a heavy brace of richly-coloured clusters, and he was followed in order by Mr. H. Prime, gardener to the Marquis of Salisbury, Hatfield, and Mr. H. H. Bacon, gardener to Mrs. W. G. Raphael, Castle Hill, Englefield Green; there were seven entries. Four came forward in the class for Madresfield Court, and here Mr. S. Barker scored with fair-sized bunches of grandly-coloured, plum-like berries; Mr. J. H. Goodacre second, and Mr. J. Shelton third.

There were only two entries for the finely-flavoured Prince of Wales variety, and here Mr. Lintott, gardener to Sir Walpole Greenwell, Marden Park, Caterham, scored, as his fruits were better coloured than the larger bunches of Mr. H. J. Alderman, gardener to H. H. Konig, Esq., Blendley Heath, Redhill. In the any other black class there were ten competitors, and the best brace of bunches was staged by Mr. Mullins, who set up finely-berried bunches; Mr. W. Allan, gardener to Colonel the Hon. C. Harbord, Gunton Park, Norwich, second.

Eleven competitors came forward in the class for Muscat of Alexandria grapes, and the competition was keen. Mr. W. Lane, gardener to Sir Edwin Durning Lawrence, Bart., King's Ride, Ascot, won first prize with splendid, large-berried bunches, very finely coloured; Mr. W. Allan second, and Mr. J. Kidd, gardener to G. Miller, Esq., Newberries, Radlett, Herts, third. In the "any other white" class Mr. A. G. Nicholls, gardener to the Duke of Wellington, Strathfieldsaye,

was placed first for huge bunches of the green-berried Calabrian Raisin; Mr. Pateman second with Lady Hutt; and Mr. F. L. Pike, gardener to H. W. Henderson, Esq., King's Langley, third with Foster's Seedling.

COLLECTIONS OF HARDY FRUITS.

The classes for a collection of thirty dishes of hardy fruits is always an interesting one, but it is rarely well filled. There were two competitors on this occasion, and Mr. J. Cornford, gardener to Major Powell Colton, Quex Park, Thanet, was placed first for admirable apples, Marguerite Marrillat and other pears of fine quality, figs, peaches, plums, and prunes; a dish of Reculver figs was of special interest. Mr. W. H. Bacon, Mote Park Gardens, came second with very fine apples, a good selection of pears, and dishes of figs, plums, mulberries, nuts, raspberries, prunes, quinces, and St. Joseph strawberries, but no peaches.

NURSERYMEN.

In the principal class open to nurserymen the requirements were a display of fruit, grown entirely in the open air, arranged on a space 30ft. by 6ft. There were five competitors, and first prize was taken by Messrs. H. Cannell and Sons, Eynsford, Kent. This firm had good size all through their fine collection, and they were ahead on colour. Their fruits were chiefly shown in dishes and shallow baskets, and piled up pyramid fashion, a few groups of baskets being raised well above the middle row so as to give effect to the whole. Particularly fine were the samples of such apples as Smart's Prince Arthur, Mere de Menage, King of Tompkins County, Gascoigne's Scarlet, Bismarck, Blue Pearmain, Peasgood's Nonsuch, Allington Pippin, Baron Wolseley, Antonowa (a pale whitish-green apple), Annie Elizabeth, Newton Wonder, Bramley's Seedling, Chelmsford Wonder, Lady Sudeley, and King of the Pippins. Pears were also well shown, and Marguerite Marrillat and others showed quite good colour. Crabs, plums, and medlars completed a very fine display. After so many years' hard fighting for first position it is pleasant to be able to record such a capital win for the Eynsford firm. Messrs. G. Bunyard and Co., Maidstone, were placed second, and they presented a very weighty collection of apples, but had not quite the usual high colouring displayed by Maidstone fruits. There were splendid baskets of Jas. Grieve, Mere de Menage, Bramley's Seedling, Rev. W. Wilks, Warner's King, Lord Derby, Lord Castlereagh, Allington Pippin, Transparent de Croncels, and Hitchin Pippin apples; White Le Brun, Marguerite Marrillat, Beurre Diel, Beurre Superfin, and Pitmaston Duchess pears. Messrs. J. Cheal and Sons, Crawley, were placed third, and they displayed brightly-coloured fruits in pleasing fashion; though very bright, the specimens were a little below the usual size, due probably to the early date of the show. The King's Acre Nurseries, Lim., Hereford, came fourth.

Premier award for a trade display occupying a space 20ft. by 6ft. was won by Mr. R. C. Notcutt, Woodbridge, who put up splendid clean specimens, richly coloured, and of excellent size; James Grieve, Allington Pippin, Coronation, The Queen, Bramley's Seedling, Blenheim Pippin, Mere de Menage, Wealthy, King of the Pippins, Alfriston, Royal Jubilee, and Lord Stradbroke apples were all capital; the latter is a comparatively new culinary variety, dark hued, and solid. Messrs. Laxton Brothers, Bedford, secured the second prize with a highly meritorious display, and their apples and pears, all of good quality, were displayed in admirable style. We were especially interested in the new Beauty of Bedford apple, a promising, highly-coloured, striped dessert variety, obtained by crossing Lady Sudeley with Beauty of Bath—a very handsome apple. Messrs. S. Spooner and Sons, Hounslow, third, their samples of Chas. Ross apple being particularly good.

A third class was provided for nurserymen, and in this case the space allowed was 12ft. by 6ft. There were two entries, and first place was given to the Barnham Nurseries, Lim., Barnham, Sussex, for an attractive exhibit, chiefly of bright-hued apples, shown off to advantage by means of coloured foliage; of Bramley's Seedling, Peasgood's Nonsuch, Lord Derby, Chas. Ross, and Newton Wonder apples this firm had fine baskets. Messrs. Paul and Son, Cheshunt, second, this firm showing a great variety of fruits, including the parsley-leaved blackberries, crabs, and Merveille de Bon Secours strawberries fruiting in tiny pots.

ORCHARD HOUSE FRUITS.

Great interest always centres in the class for a display of orchard house fruits and trees arranged on a space 24ft. by 6ft. Messrs. T. Rivers and Sons, Sawbridgeworth, were placed first with capitally-cropped trees of Emperor Alexander, Buckingham, Gascoigne's Scarlet, Cox's Pomona, and Peasgood's Nonsuch apples; Louise Bonne of Jersey and Conference pears; Coe's Golden Drop, Coe's Violet, and President plums. The picked fruits were superb, especially the examples of Cox's Orange Pippin, Ribston Pippin, Peasgood's Nonsuch, and St. Edmund's Pippin apples, all glorified almost beyond recognition; Guigne de Winkle cherries, grand Marguerite Marrillat, Souv. du Congrès, Doyenne du Comice, and St. Luke's pears; and Primate, Late Orange, Monarch, President, and Coe's Golden Drop plums, and Sea Eagle peaches—altogether a grand display.

Messrs. G. Bunyard and Co., Lim., Maidstone, were placed second, their picked fruits being of particularly high class; Marguerite Marrillat, Doyenne du Comice, Uvedale's St. Germain, Pitmaston Duchess, St. Luke, and Durondeau pears were altogether excellent. The King's Acre Nursery Company, Hereford, were placed third, and though they were very little behind on their picked fruits (though these were very fine), they seemed to lack nothing when the pot fruit trees, clean and heavily cropped with first-rate fruits, were considered.

MARKET GROWERS' CLASSES.

Messrs. Gaskain and Whiting, Dargate, Faversham, were again successful in winning first prize for twenty baskets of cooking and dessert varieties in the section open only to market growers. Last year this firm showed grandly, and their fruits were on this occasion scarcely below last year's high standard. There were superb specimens of Warner's King, Peasgood's Nonsuch, Loddington, Lord Derby, Cox's Pomona, Blenheim Pippin, Bramley's Seedling, Ribston Pippin, Rival, Chas. Ross (splendidly coloured), Cox's Orange Pippin, American Mother, and Lady Henniker.

In the smaller class, for six baskets each of cooking and dessert varieties, Mr. G. Packman, gardener to Colonel Honeyball, Teynham, Kent, led, and here again grand fruits were shown, the varieties being Warner's King, Mere de Menage, Stone Apple, Bramley's Seedling, Lord Derby, Peasgood's Nonsuch, Chas. Ross, Cox's Orange Pippin, Allington Pippin, Worcester Pearmain, Paraquet, and Duchess's Favourite. The Swanley Horticultural College came second; and H. Lumley Webb, Esq., Ham Green, Upchurch, Sittingbourne, was placed third.

COLLECTIONS OF APPLES.

In the gardeners' and amateurs' class for two dozen dishes of apples, sixteen cooking and eight dessert varieties, there were five entries, and the silver cup and first prize fell to Mr. J. Whittle, gardener to Colonel Borton, Hunton, Maidstone, for a fine collection of clean, finely-developed fruits. The varieties, all excellent, were Gascoigne's Scarlet, Bismarck, Lane's Prince Albert, Hambling's Seedling, Belle Pontoise, New Hawthorndeu, Lady Henniker, Lord Derby, Mere de Menage, Loddington, Annie Elizabeth, Emperor Alexander, Peasgood's Nonsuch, Warner's King, Bramley's Seedling, Wealthy, Allington Pippin, Rival, Ribston Pippin, Cox's Orange Pippin, Christmas Pearmain, Chas. Ross, and Melon apples; Mr. W. A. Bacon, The Mote Gardens, Maidstone, came second, and Mr. T. Pateman, Welwyn, third.

Out of six competitors in the class for a dozen dishes of cooking and six of dessert apples, Mr. B. J. Mercer, gardener to H. G. Kleinwort, Esq., Wierton Place, Maidstone, set up a beautifully even and clean collection and obtained the premier award; Mr. J. Cornford, Thanet, second; and Mr. T. Herbert, gardener to T. Charlesworth, Esq., Nutfield Court, Nutfield, third.

The best eight dishes of cooking and four dishes of dessert apples came from Mr. J. Mullins, Eastnor Castle Gardens, whose fruits of Tyler's Kernel, Wealthy, Rival, Cox's Orange Pippin, and Emperor Alexander were finely coloured and of good size; Mr. J. Kidd, Radlett, second; and Mr. H. E. Wallis, gardener to Mrs. Trevor Goff, Sherfield Hall, Basingstoke, third.

The finest half-dozen dishes of cooking apples came from Mr. J. Whittle, Hunton Gardens, Maidstone, who put up Peasgood's Nonsuch and Bismarck in fine form; Mr. W. H. Bacon second. The best half-dozen dishes of dessert apples came from Mr. G. Mullins, who contributed beautiful fruits of Rival, Cox's Orange Pippin, King of the Pippins, Jas. Grieve, Wealthy, and Ribston Pippin; Mr. W. H. Bacon second.

COLLECTIONS OF PEARS.

Four competitors staged eighteen dishes of dessert pears, and this class made a good show. The first prize and silver cup went to Mr. W. H. Bacon, The Mote Gardens, Maidstone, for a handsome lot of fruits, wherein the varieties Marguerite Marrillat, Durondeau, Clapp's Favourite, Souv. du Congrès, Conference, Triomphe de Vienne, and Beurre Baltet pear were notably fine; Mr. J. Whittle second, and Mr. Pateman third.

The Fruiterers' Company's silver medal and £2 offered as first prize for a dozen dishes of dessert pears went to Mr. J. Cornford, Quex Park Gardens, Thanet, whose best dishes were of Gansel's Bergamot, Beurre Alexandre Lucas, and Pitmaston Duchess; Mr. J. Ridd second.

Mr. J. Shelton led for nine dishes of pears, and had Triomphe de Vienne in good form; Mr. J. Whittle scored for nine dishes of pears, and Mr. B. J. Mercer was second, while for three dishes of stewing pears Mr. J. Cornford led with Uvedale's St. Germain, Catillac, and Gilogil.

PLUMS.

The best set of three dishes of plums came from Mr. W. Messenger, gardener to C. H. Berners, Esq., Woolverstone Park, Maidstone, his varieties being President, Coe's Golden Drop, and Monarch; Mr. J. Hill, Kingston Lacy, Wimborne, second, with Grand Duke, President, and Primate, and in all cases the fruits were fine. Mr. F. G. Gerrish, gardener to J. G. Williams, Esq., Pendley Manor, Tring, led for damsons or bullaces, and Mr. G. Mullins and Mr. Gerrish were placed first and second respectively for Morello cherries.

DISTRICT COUNTY CLASSES.

In the district county section each district has two classes, one for four dishes of cooking and two dishes for dessert apples, and one for six dishes of dessert pears. In the apple class the prizes offered were, first, 4l and second-class single fare from exhibitor's nearest railway station to London; second, 15s., and third single rail fare. For pears the prizes offered were, first, 30s., and single third rail fare; second, 20s., and single third rail fare.

In the Kent growers' section first place for apples was won by Mr. J. Bond, gardener to G. H. London, Esq., Wye, who showed beautiful fruits of Jas. Grieve, King of the Pippins, and Bramley's Seedlings; Mr. J. Coleman, gardener to Captain S. G. Reid, The Elms, Yalding, second. The latter was first in the pear class with very fine dishes of Conference, Durondeau, Marguerite Marillat, Pitmaston Duchess, and Doyenne du Comice; Mr. Bond second.

The next section was open to growers in Surrey, Sussex, Hants, Dorset, Somerset, Devon, and Cornwall, and here Mr. T. Turton, gardener to F. J. B. Wingfield Digby, Esq., Sherborne Castle, Dorset, scored for pears, his Doyenne Boussoch and Doyenne du Comice being very fine; Mr. J. Hill, Kingston Lacey, second. For apples, Mr. J. A. Stidston, Bishopsteignton, Devon, won first prize finely, his Rougemont, Chas. Ross, Peasgood's Nonsuch, and Gascoigne's Scarlet being especially good; Mr. A. Tidy, gardener to C. H. Combe, Esq., Cobham Park, Surrey, came second with very heavy culinary apples; four entries.

In the section open to growers in Wilts, Gloucester, Oxford, Bucks, Berks, Beds, Herts, and Middlesex, there were four entries of pears, and first prize fell to Mr. A. Carlisle, gardener to C. Gurney, Esq., Henlow Grange, Biggleswade, for handsome dishes of Clapp's Favourite, Pitmaston Duchess, Louise Bonne of Jersey, and Marguerite Marillat; Mr. C. Page, gardener to J. B. Fortescue, Esq., Maidenhead, second. For apples, Mr. A. Carlisle scored among seven competitors with fine samples of Bramley's Seedling, Peasgood's Nonsuch, Blenheim Pippin, Ribston Pippin, and Cox's Orange Pippin, all brightly coloured and very clean; Mr. T. J. Finch, gardener to the Earl of Suffolk, Charlton Park, Malmesbury, a capital second.

A little difficulty arose in the section for growers in Essex, Suffolk, Norfolk, Cambridge Hants, and Rutland; for the apple class by far the finest fruits were exhibited by Mr. G. Davison, gardener to Colonel Petrie, Westwick, Norwich, and first prize was placed on his card. Eventually "Disq." was pencilled on the card, and the red-lettered prize slip crossed through, and a written note from the Rev. W. Wilks stated, "Prize in abeyance owing to protest, which must be investigated." At the same time, "1st prize" was pencilled on the class-card belonging to Mr. A. Andrews, gardener to the Right Hon. J. W. Lowther, Wickham Market; and second on the card from Mr. A. Humphery, gardener to Sir Montagu Turner, Havering, Romford. We understand the protest was on the ground that Colonel Petrie has a fruit farm, and is therefore a trader. Mr. G. Davison was placed first for pears, and staged superb specimens of Marguerite Marillat, Souv. du Congrès, Doyenne du Comice, Triomphe de Vienne, Pitmaston Duchess, and Durondeau; Mr. W. Allan, gardener to Colonel the Hon. C. Harbord, Gunton Park, Norwich, second. There appeared to be no question as to Colonel Petrie's or Mr. Davison's qualifications in the pear class, curiously enough.

There was but one entry each of apples and pears in the section open to growers in Lincoln, Northampton, Warwick, Leicester, Notts, Derby, Staffordshire, Shropshire, and Cheshire, and so in both classes the premier award fell to Mr. J. Taylor, gardener to F. Bibby, Esq., Hardwicke Grange, Salop, his best dishes being of Beurre de Mortillet pears and Peasgood's Nonsuch and Rival apples. The best six dishes of pears for growers in Worcester, Hereford, Monmouth, Glamorgan, Carmarthen, and Pembroke came from Mr. C. Crooks, Impney Hall Gardens, Droitwich, his Clapp's Favourite being very good. For apples F. Paget Norbury, Esq., The Norrest, Malvern, beat Mr. Crooks.

Mr. Thos. Jones, Ruabon, of sweet pea fame, scored for pears in the section open to growers in other counties of Wales, and he showed good dishes of Princess, Beurre de Mortillet, and Dr. Jules Guyot; he also secured first prize for apples, and was not troubled by other competitors. The only exhibitor in the section for the six northern counties of England and the Isle of Man was Mr. J. C. McPherson, gardener to the Earl of Londesborough, Market Weighton, who secured first prize for both apples and pears; Allington Pippin and Peasgood's Nonsuch apples, and Souv. du Congrès, Pitmaston Duchess, and Conference pears were among his best dishes.

Mr. Jas. Duff, gardener to C. L. Gordon, Esq., Castle Douglas, scored for apples in the Scottish class, and showed remarkably clean and bright examples of Duchess of Oldenburgh, Gascoyne's Scarlet, Lady Sudeley, and Worcester Pearmain—as clean and good as though from under glass; Mr. J. J. Steward, St. Fort Gardens, Newport, Fife, second. There were not any pears shown in this section. Among Irish growers Mr. W. Smart, gardener to J. Congreve, Esq., D.L., Mount Congreve, Waterford, was the only exhibitor of pears, and gained first prize. For Irish-grown apples Mr. T. E. Tomalin, gardener to the Earl of Bessborough, Piltown, Co. Kilkenny, led, and his dishes of Ecklinville, Tyler's Kernel, Hambling's Seedling, and Lady Sudeley were capital; Mr. C. B. Brond, Aghery, Conna, Co. Cork, second.

DESSERT APPLES, SINGLE DISHES.

In these classes we give only the names of the variety, the number of exhibits, and the chief prize-winners.

Adam's Pearmain, ten entries; Mr. T. J. Finch, Malmesbury. Allington Pippin, seventeen entries; Mr. J. Reynolds, gardener to W. Castle, Esq., Holland House, Barton Mills, Suffolk. American Mother, ten entries; Mr. A. Basile, Woburn Park Gardens, Weybridge. Barnack Beauty, four entries; Mr. C. Crooks, Impney. Belle de Boskoop, four entries; Mr. J. Coleman, Yalding. Ben's Red, six entries; Mr. W. Messenger, Ipswich—a fine dish. Blenheim Orange, fifteen entries; Mr. J. T. Tubbs, gardener to J. Walter, Esq., Bearwood, Wokingham.

Chas. Ross, thirteen entries; Mr. F. King, gardener to Rev. H. A. Bull, Westgate-on-Sea. Christmas Pearmain, five entries; Mr. A. Basile. Claygate Pearmain, sixteen entries; Mr. A. Carlisle—very fine dish. Cockle's Pippin, four entries; Mr. A. Tidy. Coronation, three entries; Mr. G. Richardson, Newton Abbot. Cox's Orange Pippin, seventeen entries; Mr. J. S. Kelly, gardener to the Duchess of Albany, Claremont, Esher—a very richly coloured dish. Duke of Devonshire, six entries; Mr. J. Coleman. Egremont Russett, eight entries; Mr. J. Bond, Wye. James Grieve, nine entries; Mr. F. P. Norbury, Malvern. Houblon, no entries. King of Tompkin's County, five entries; Mr. A. Tidy. Lord Hindlip, three entries; Mr. T. J. Finch.

Mannington Pearmain, two entries; Mr. J. Hill. Margil, five entries; Mr. A. Basile. Reinette du Canada, one entry; Mr. G. Richardson. Ribston Pippin, seventeen entries; Mr. W. Allan, Gunton. Rival, eight entries; Mr. W. Messenger—extra fine fruits. St. Edmund's Pippin, five entries; Mr. J. T. Tubb. Scarlet Nonpareil, two entries; second only, to Mr. C. Page. St. Everard, two entries; Mr. C. Page. Wealthy, thirteen entries, Mr. A. Basile. William Crump, no entry.

Any early dessert apple not named above, seventeen entries: Mr. Andrews first with fine Worcester Pearmain; Mr. W. Allan second with Benoni. Any other late dessert variety not already named, fourteen entries: Mr. G. Richardson first with Ballinora, and Mr. J. T. Tubb second with Ross Nonpareil—a fine dish.

COOKING APPLES.

Alfriston, four entries; Mr. A. Tidy. Annie Elizabeth, ten entries; Mr. J. Coleman. Beauty of Kent, three entries; Mr. W. Allan. Bismarck, six entries; Mr. J. Coleman. Blenheim Orange, ten entries; Mr. H. Engell, Hickling—fine dish. Bramley's Seedling, eleven entries; Mr. T. Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, Addlestone—a fine dish. Dumelow's Seedling, seven entries; Mr. G. Richardson. Byford Wonder, no entry. Crimson Bramley's, no entry. Ecklinville, eight entries; Mr. A. Basile. Edward VII., four entries; Mr. A. Andrews. Emneth Early, one entry; Mr. J. R. Smith, Bedgebury Park, Goudhurst. Emperor Alexander, five entries; Mr. W. Stevenson, gardener to G. E. Pearson, Esq., Brickendonbury.

Gascoigne's Scarlet, seven entries; Mr. A. G. Nicholls, Strathfieldsaye. Golden Noble, six entries; Mr. A. Andrews. Grenadier, five entries; Mr. T. E. Tomalin. Hambling's Seedling, six entries; Mr. T. A. Tomalin—splendid fruits. Hector Macdonald, two entries; Mr. J. Copp, Teignmouth. Hormead Pearmain, three entries; Mr. J. Coleman. King of Tompkin's County, three entries; Mr. J. Coleman. Lane's Prince Albert, six entries; Mr. W. Stephenson. Lord Derby, eleven entries; Mr. C. Johnson, The Vicarage Gardens, Yalding.

Mère de Ménage, eight entries; Mr. G. Richardson—grand dish of weighty fruits. Newton Wonder, eight entries; Mr. J. Coleman. Norfolk Beauty, three entries; Mr. A. Andrews. Peasgood's Nonsuch, six entries; Mr. A. Andrews—fine dish. Pott's Seedling, six entries; Mr. J. Coleman. Rev. W. Wilks, four entries; Mr. F. L. Pike, King's Langley. Royal Jubilee, five entries; Mr. A. Andrews. Stirling Castle, eight entries; Mr. F. P. Norbury. The Queen, seven entries; Mr. A. Andrews. Tower of Glamis, eight entries; Mr. A. Tidy. Warner's King, nine entries; Mr. G. Richardson—a heavy dish.

Any other culinary variety, fourteen entries: Mr. T. E. Tomalin, Pilton, with Loddington; Mr. G. Johnson, Yalding, second, with the same variety.

CHOICE DESSERT PEARS. SINGLE DISHES.

The same conditions prevailed in this section as in those for both culinary and dessert apples, the prizes being 7s. and 5s. for first and second places.

Beurre Alexander Lucas; three entries; Mr. T. Turton. Beurre d'Amanlis, six entries; Mr. H. C. Gardner, gardener to Lord Foley, Ruxley Lodge, Esher. Beure d'Anjou, Mr. T. Turton. Beurre Bose, four entries; Mr. T. Turton. Beurre Damont, two entries; Mr. A. Basile. Beurre Hardy, four entries; Mr. W. Messenger. Beurre Peron, two entries; Mr. W. Allan. Beurre Superfin, four entries; Mr. T. Turton. Blickling, one entry; Mr. W. Allan. Charles Ernest, three entries; Mr. G. D. Davison. Comte de Lary, three entries; Mr. A. Tidy.

Conference, four entries; Mr. G. D. Davison. Directeur Hardy, one entry; Mr. J. Taylor, Hardwicke. Doyenne du Comice, eight entries; Mr. G. D. Davison, Durondeau, ten entries; Mr. G. D. Davison. Easter Beurre, four entries; Mr. G. D. Davison. Emile d'Heyst, six entries; Mr. W. Messenger. Fondante d'Autumn, four entries; Mr. W. Allan. Fondante Thirriot, three entries, Mr. W. Messenger. Glou Morceau, four entries; Mr. G. D. Davison. Gratioli of Jersey, one entry; Mr. W. Allan. Josephine de Malines, five entries; Mr. T. Turton. Le Brun, two entries; Mr. F. A. Billings, Launceston. Le Lectier, four entries; Mr. Thos. Stevenson.

Louise Bonne of Jersey, eight entries; Mr. J. Bond. Marie Louise, five entries; Mr. G. D. Davison. Nouvelle Fulvie, three entries; Mr. G. D. Davison. Olivier des Serres, three entries; Mr. T. Turton. Pitmaston Duchess, six entries; Mr. G. Davison. Souv. du Congrès. Mr. A. Basile. Thompson, three entries; Mr. S. Barker, Clumber. Triomphe de Vienne, two entries; Mr. G. Davison. Winter Nelis, six entries; Mr. T. Turton.

Any early pear not named above, thirteen entries, Mr. W. Allan first with Williams' Bon Chretien; Mr. Andrews second with the same variety. Any other late pear not named above, eight entries, Mr. T. Turton first, with a fine dish of Beurre Baltet Père; Mr. W. Allan, second, with Marie Louise d'Uccle.

AFFILIATED SOCIETIES' COMPETITION.

The Affiliated Societies' Silver Cup for a collection of six dishes of cooking and six dishes of dessert apples, and six dishes of dessert pears, six fruits to a dish, was won on this occasion by the Ipswich and District Gardeners' and Amateurs' Association, with a fine set. A few of the finest dishes were of Lord Derby, Lane's Prince Albert, Gascoigne's Scarlet, Peasgood's Nonsuch, Chas. Ross, Jas. Grieve, and Rival apples, and

Pitmaston Duchess, Durondeau, Beurre Diel, and Doyenne Boussoch pears.

Second prize, a silver-gilt Banksian medal, went to the Colchester and District Gardeners' Association, who had fine fruits, admirably staged. Third in order of merit was the East Anglian Horticultural Club.

OTHER EXHIBITS.

Mr. George Pyne, Denver, Topsham, Devon, was awarded a silver Hogg Memorial Medal for a grand dish of the Rev. W. Wilks apple, of exceptionally fine quality and size. Mr. W. H. Hawthorn, gardener to Mrs. Chas. Charrington, Broadoaks, West Byfleet, Surrey, exhibited two dozen dishes of culinary and dessert apples, and a dozen dishes of pears, all of fair quality.

Mr. C. Turner, Slough, showed the very fine new apple named Arthur Turner, and Messrs. Merryweather and Sons exhibited their splendid new Merryweather damson, and gained for it a F.C.C. on this occasion.

MEDALS AWARDED.

In the trade classes already referred to the following medals were awarded as prizes: Premier class, 30ft. by 6ft.—Gold Medal, to Messrs. H. Cannell and Sons; silver-gilt Hogg Memorial medal, to Messrs. George Bunyard and Co., Maidstone; silver-gilt Knightian medal, to Messrs. J. Cheal and Sons, Crawley; silver-gilt Banksian medal, to King's Acre Nurseries, Lim., Hereford; silver Knightian medal, to Messrs. Wm. Seabrook and Sons, Chelmsford.

Second-class, 20ft. by 6ft. — Silver-gilt Knightian medal, to Mr. R. C. Notcutt, Woodbridge; silver-gilt Banksian medal to Messrs. Laxton Brothers, Bedford; silver Knightian medal, to Messrs. S. Spooner and Sons, Hounslow.

Third-class, 12ft. by 6ft.—Silver-gilt Banksian medal, to the Barnham Nurseries, Lim., Barnham, Sussex; silver Knightian medal, to Messrs. Paul and Son, Cheshunt; silver Banksian medal, to Mr. G. W. Miller, Wisbech.

Orchard House Fruit and Trees. — Gold medal, to Messrs. Thos. Rivers and Sons, Sawbridgeworth; silver-gilt Hogg Memorial medal, to Messrs. G. Bunyard and Co., Maidstone; and silver-gilt Knightian, to King's Acre Nurseries, Lim., Hereford.

BALSAMS.

Within recent years several distinct species of impatiens have been introduced into cultivation, some of which have now become popular garden plants. The oldest of all, however, namely, the common Balsam (Impatiens balsamina), does not occupy the high position in gardens that it once did. There is, however, no reason to account for their comparative neglect, as well-grown examples are very handsome, and, what is more, they retain their beauty for a considerable time. In the typical kind, which was introduced from Tropical Asia in 1596, the flowers are single, but now the double-flowered varieties are mainly grown. What is known as the camellia-flowered balsam is a particularly fine strain, the flowers being large, double, and with a wide range of attractive colours. The main essentials to success in the culture of these balsams is to take care that the plants do not suffer any check from the seedling stage till they are in flower. If sown towards the end of March or in April the seed will, in a gentle heat, germinate quickly. As soon as the young plants are sufficiently advanced they should be potted off, using a good open, fairly rich compost. They must be shifted on directly they are sufficiently advanced, and may be flowered well in pots from seven to ten inches in diameter. As they grow quickly the plants must be frequently turned round to prevent them becoming one-sided. S. W.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

National Chrysanthemum Society.

The opening of the chrysanthemum show season commenced on October 1 and 2, when the N.C.S. helds its early exhibition at the Crystal Palace. Except in a few classes competition was not keen, but the flowers were notably good in size and colour, and were remarkably fresh. We remember several larger early shows, but none at which brilliant colouring has been more pronounced. The traders came out in strong force, and put up very atractive groups of chrysanthemums, dahlias, Michaelmas daisies, begonias, etc.

Not many novelties were forthcoming, but Yellow Moneymaker (Messrs. Cragg, Harrison, and Cragg), Golden Diana (Messrs. Todd and Co., Edinburgh), and Mrs. Richard Hamilton (Messrs. Lowe and Shawyer, Uxbridge), each gained an F.C.C.

OPEN CLASSES.

There were two competitors for the silver cup offered as first prize by the President of the Society, Sir Albert Rollit, LL.D., for the best floral display of chrysanthemums, plants and cut flowers, associated with suitable foliage. The space allowed was a semicircle, 14ft. by 7ft. Mr. Norman Davis, Framfield, Sussex, was a capital first, and his bold disposition of big yellow and white blooms was greatly admired. In the foreground Mr. Davis used early-flowering outdoor varieties, and provided an edging of ferns. Berberis and purple plum foliage was used sparingly in the stands of blooms. Messrs. J. Peed and Son, West Norwood, secured second place, and caladiums were associated with their chrysanthemums.

Mr. Thos. Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, Addlestone, was the only exhibitor of a dozen Japanese blooms, distinct, shown on boards. He was awarded first prize for grand examples of Frances Joliffe, Mrs. Thos. Stevenson, D. B. Crane, Hon. Mrs. John Ward, Lady Talbot, Japan, Mrs. R. Luxford, and Master James. For six big blooms, Japanese, Mr. T. J. Broom, gardener to Miss Langworthy, Gay's House, Holyport, led among four competitors, and staged Amarantha, Master James, and Henry Perkins finely; Mr. G. Mileham, gardener to A. T. Miller, Esq., Emlyn House, Leatherhead, second, and Mr. C. Pullen, gardener to G. P. B. Fores, Esq., Blenheim, Raynes Park, S.W., third.

Early-flowering pompon varieties, twelve bunches, is apparently a rather difficult class to fill, and Mr. J. Smellie, Pansy Gardens, Busby, near Glasgow, annexed the first prize, and showed La Luxembourg, Canari, St. Croutts, Scarlet Gem, the old Piercy's Seedling, and other good varieties of this interesting, but, alas, not very popular section.

The class for a dozen bunches of undisbudded blooms, grown out of doors, bunches not to exceed eighteen inches in diameter, brought out two competitors, and here Mr. J. Smellie was a good first with fine flowers rather densely packed into full-sized bunches; Crimson Polly, La Parisienne, Elstob Yellow, Mrs. J. Fielding, Hector, and Cream Perrier were the best of his varieties; Mr. J. Emberson, Walthamstow, second. Two exhibitors came forward in the class for a dozen bunches of outdoor grown, disbudded chrysanthemums. Mr. Thos. Stevenson gained first prize with handsome fresh blooms of Cranford Pink, Almirante, Princess, Debutante, Emperor, El Draco, Dolores, Bronze Soleil d'Octobre, Framfield Early White, Betty Spark, Hollicot Yellow, and Hollicot Bronze; Mr. A. Henson, Milford House, St. Peter's Avenue, Kettering, a good second.

Mr. T. Stevenson scored for six bunches of early-flowering Japanese or decorative varieties with lovely flowers of Almirante, Cranford Pink, Soleil d'Octobre, Emperor, El Draco, and Debutante; Mr. A. Henson second, and Mr. J. Emberson third; five entries. The best vase of three blooms of any Japanese variety was one of the Hon. Mrs. John Ward, shown by Mr. T. Stevenson; second award fell to Mr. G. Mileham, for White Queen; and third to Mr. R. J. Gladwell, gardener to A. Gosheron, Esq., Tennyson Road, South Norwood, for D. B. Crane.

In each of the two classes for a vase of early-flowering singles, Mr. J. Smellie was the only exhibitor, and he gained second prize in each case; his flowers had suffered somewhat during the long journey.

AMATEURS.

In the amateurs' division Mr. A. Henson led the way for six bunches of early chrysanthemums, disbudded, and he showed Almirante, Cranford Pink, and Countess in fine style; Mr. H. Dunkley, St. Peter's Avenue, Kettering, second. For the same number of bunches of undisbudded, outdoor-grown chrysanthemums, Mr. Henson was again to the front, and here his Roi des Blancs, Perle Chatillonaise, Goacher's Crimson, and Improved Polly were very beautiful; Mr. H. Dunkley second; and Mr. C. Fox, Linden Gardens, Tunbridge Wells, third. Mr. D. B. Crane, Archway Road, Highgate, was the only exhibitor of early pompons, and was awarded first prize.

In the trade excluded class for a vase of chrysanthemums and foliage, Mr. C. Fox, Tunbridge Wells, was placed first, but it was a pity he used large fronds of maidenhair fern, when other more appropriate foliage was at command; Mr. T. W. Stevens, Donnington, Laurie Park, Sydenham, second; and Mr. A. Henson third.

Mr. H. Dunkley had the best three bunches of undisbudded early varieties, winning with Fee Parisienne, Roi des Blancs, and Leslie. Mr. C. Fox second, and Mr. Henson third. For three bunches, disbudded, Mr. Henson won with Miss E. Foster, Golden Queen, and Framfield Early White; Mr. H. Dunkley second.

DECORATIVE CLASSES.

Mr. T. W. Stevens scored for a dinner table decoration of chrysanthemums, and led with a pleasing design, light and elegant, of yellow and bronze flowers, and croton foliage; Mrs. W. C. Roelink, Markhouse Avenue, Walthamstow, second; and Mrs. A. M. Brill, Southdown Avenue, Brighton, third; the latter showing lilac-coloured flowers, but spoiled the effect by having eight blooms under the stands, on the cloth; eight entries.

Mrs. Roelink was the only exhibitor in the amateurs' class for a table decoration, and she was deservedly awarded first prize for her pleasing design in which single flowers of yellow and bronze hue were used with rare judgment.

Mr. T. Stevens was premier prizewinner for three epergnes of chrysanthemums, his central effort consisting of white and crimson bronze flowers; Mr. A. W. Trossell, gardener to H. Attenborough, Esq., The Avenue, Beckenham, second; and Mrs. A. Robinson, Norhyrst, Park Hill, Carshalton, third.

Mrs. Robinson scored for one epergne with a light design; Mr. T. W. Stevens second, and Mr. Fox third.

The only vase of early-flowering single varieties, arranged with suitable foliage, was put up by Mr. J. Smellie, and was a bright contribution that received a first prize. Mr. J. Emberson led for a basket of blooms and suitable foliage with a handsome arrangement of golden, yellow, and crimson flowers with asparagus sprays and fern fronds; Mr. A. R. Bide, Highlands, Farnham, second; Mr. R. Bugden, Gipsy Hill, Upper Norwood, was awarded first prize for a basket of autumn foliage and berries, but the arrangement was rather heavy and dull.

NON-COMPETITIVE.

A particularly pleasing exhibit of disbudded chrysanthemums, chiefly from out of doors, was made by Messrs. Cragg, Harrison, and Cragg, Heston, Hounslow. This large exhibit was arranged in the style of a formal garden, the four corners of a square being filled in with large vases of beautiful blooms, set up over ferns. In the centre was a square-based pyramid, composed of handsome blooms of Juliet, Framfield Early White, J. W. Streater (a yellow H. W. Thorpe), and Yellow Moneymaker, a soft yellow sport from the popular white Moneymaker. The whole of this garden was about 30ft. square, so readers will have a fair idea of its extent. Besides those named, there were fine vases of blooms of Kara Dow, the crimson-scarlet Almirante, Cranfordia, Heston Yellow, Mrs. Cragg, Cranfield Pink, Mrs. Scott, and Mdme. A. Nonin.

Messrs. W. Wells and Co., Merstham, presented a big imposing display, composed of great sheaves of phloxes and delphiniums and large stands of Climax, Grace, and Miss Brazier Michaelmas daisies, with perpetual carnations in variety in the centre, including the fine new scarlet, named The Champion. There was also a great flanking group of early chrysanthemums, set up in vases and tall stands, the most striking varieties being the golden Leslie, the pink Normandie, Mrs. J. Fielding, Goacher's Crimson, and Roi des Blancs.

Ferns were contributed by Messrs. H. B. May and Sons, Edmonton, together with chrysanthemums and begonias. Mr. J. Emberson, Walthamstow, displayed an excellent selection of cactus, pæony-flowered, pompon, and collarette dahlias in stands of varying size, and associated the flowers with asparagus and other suitable foliage. Messrs. Thos. S. Ware, Feltham, used pæony-flowered dahlias to secure the chief effect in their display, but the low pyramids of cactus dahlias under the tall stands of the other sorts was a good idea. Prominent among the "pæonies" were The Geisha, Bertha von Suttner, Flamingo, Mrs. G. Gordon, Pennant, Dusky Queen, Queen Mary, and Mrs. Alfred Platt. The same firm added to the importance of their contribution by staging tuberous begonias finely, as well as hardy border flowers in variety.

Mr. J. B. Riding, Chingford, again gave prominence to collarette dahlias, and provided for them a capital background of pæony-flowered and cactus varieties. Among the collarettes we were attracted by Henri Farman, Maurice Rivoire, Geant de Lyons, new; Maroc, a glorified Ideal; Dora Fisher, new, the only real pink sort yet; Albert Maumene, General de Solis, vivid scarlet; Ville de Schildt, new, orange-salmon; S. von Schelking, new, straw-yellow, with crimson shading towards the base, and light yellow collar. Mr. A. H. Cole, Swanley, showed a capital lot of zonal pelargoniums, growing in small pots, and carrying good heads of bloom; these were from the old "Home of Flowers."

The choicer Michaelmas daisies were put up in most charming fashion by Mr. H. J. Jones, Ryecroft Nursery, Lewisham. A white background proved eminently suitable for the soft lilac, blue, lavender, and rose colouring of these beautiful autumn flowers. Stands about 6ft. high were filled gracefully with sprays of one variety, and the effect was excellent. Outstanding varieties were Climax, Micky Adams, Mabs, Lil Fardell, and Queen, among large-flowered sorts; and Ideal, Bianca, and Chastity among the graceful small-flowered kinds. This splendid and beautifully-arranged exhibit was further brightened by stands of yellow and pink chrysanthemums, and finished off with an edging of Helxine Solieroli.

Messrs. Wm. Cutbush and Son, Highgate, had a very handsome display of Michaelmas daisies, set up in huge spreading bouquets from 4ft. to 6ft. through, set over a groundwork of flowers in vases. Sirius, Climax, Avalanche, Ideal, and Little Bo Peep were the varieties used so boldly, while the double Peggy Ballard provided a central mound of bright colouring. Messrs. W. Russell and Son, Brentwood, contributed a collection of apples and a group of ivies and other shrubs. The Four Oaks Spraying Machine Company, Sutton Coldfield, exhibited spraying machines, syringes, etc.

MEDAL AWARDS.

Gold.—Mr. H. J. Jones, Ryecroft Nursery, Lewisham; Messrs. Thos. S. Ware, Lim., Feltham; Messrs. W. Wells and Co., Merstham; Messrs. Cragg, Harrison, and Cragg, Heston, Hounslow.

Small Gold.—Messrs. Wm. Cutbush and Son, Highgate; Messrs. H. B. May and Sons, Edmonton.

Silver-Gilt.—Mr. J. B. Riding, Chingford.

Large Silver. — Mr. J. Emberson, Walthamstow.

Silver,—Messrs. David Russell and Son, Brentwood.

Small Silver.—Mr. A. H. Cole, Swanley.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE.—September 29.

Present: Mr. E. A. Bowles, M.A. (in the chair), Prof. I. B. Balfour, Messrs. J. W. Odell, G. Wilson, W. Hales, R. Hooper Pearson, A. R. Rolf, F. J. Chittenden (hon. sec.), and Rev. J. Jacob, visitor.

MITES ON LIME TREE.—Mr. A. D. Michael reported that the mites on the lime sent from Bristol to the last meeting were the lime-tree form of the common Tetranychus telarius, sometimes separated under the name T. tiliarum, but really not distinct. It seems unpleasantly abundant and most destructive.

NARCISSUS BULBS DISEASED. — The bulbs sent by the Rev. J. Jacob to the last meeting were referred to Kew, and it is reported that the trouble, which consists of an internal rotting starting apparently from the base, and proceeding gradually throughout the mass, is due primarily to the fungus Fusarium bulbigenum, Cke. and Mass. Eelworms, mites, etc., are secondary. Numerous narcissus bulbs attacked by this fungus have been received recently, and a detailed account is in preparation. Some discussion took place regarding the bulbs, which presented some curious features. There were strange outgrowths from the base presenting somewhat the appearance of roots covered with root hairs, and about $\frac{3}{8}$ to $\frac{1}{2}$ an inch in length. Examination proved them to consist of masses of eelworms, some of which were active, and mixed with them a few eggs. Some varieties were attacked, while others growing side by side with them were immune. It was thought that the attack began while the bulbs were still in the ground, and was so little advanced when they were lifted that it was unnoticed then. There seemed no doubt from Mr. Jacob's description that the damage extended rapidly as the season of storage advanced. Mr. Jacob showed further examples.

ARISTOLOCHIA SEMPERVIRENS FRUITING.—Mr. Bowles showed, on behalf of Canon Ellacombe, some fruits of this aristolochia from Bitton. There seems no previous record of its fruiting in this country.

SEMPERVIVUM ARBOREUM. — Mr. Langworthy sent from his garden at Claygate an inflorescence of this Portuguese sempervivum, with small leaf rosettes at the apex of each of the branches of the inflorescence, which had almost dried up.

SOLANUM CRISPUM. — He also sent a section of a branch of Solanum crispum, measuring about $3\frac{1}{2}$ inches in diameter, cut from a plant growing outdoors at Claygate.

CROCUS PULCHELLUS FASCIATED.—Mr. E. A. Bowles showed Crocus pulchellus with two groups of perianth pieces, one containing six, the other seven parts, arising from the top of a common tube. The stamens were normal in number.

PRIMULA VINCÆFLORA.—A Botanical Certificate was unanimously recommended to this beautiful species, shown by Prof. I. Bayley Balfour from the Botanic Garden at Edinburgh. It was introduced by Forrest, who collected the seed in Yunnan. Its solitary oblique flowers are $1\frac{1}{2}$ inches to 2 inches in diameter, of a rich purplish violet, and and have the anterior stamens bent back, bringing the anthers near together. Three other species, of which P. Elwesi is in cultivation but has not yet flowered, share this character with vincæflora, and form a unique and very beautiful group in this family. The seed from which the present plant was raised was collected in 1911.

ABNORMAL GLOXINIAS.—Mr. Odell reported that he had examined the abnormal gloxinias sent to the last meeting by Mrs. Myles Kennedy, and found that the erect flower had four petaloid outgrowths originating from the base of the corolla and adnate for two-thirds of the length of the tube, terminating with a free apex. The outgrowths were similar in structure and colour to the corolla, and reversed as they are in some semi-double primulas, the spotted surfaces of the outgrowths being turned to the inner surface of the corolla. The stamens corresponded in number and position to the outgrowths (two being suppressed), the filaments being adherent to the walls of the corolla and to the centre of the outgrowths. The anthers were basifixed at the apex of the outgrowths. In place of the normal six glands were five unequal structures, bifid, and thus resembling staminodes. The ovary was normal.

Mr. Odell showed other abnormal forms of gloxinias for comparison.

GLASSINESS IN APPLES. — Specimens showing this peculiar appearance of semi-transparency were shown. The trouble, which is apparently of physiological origin, is very prevalent this year, and no cure is known.

CYTISUS FASCIATED.—Mr. Gaskell sent a branch of fasciated Cytisus—a peculiarity not uncommon in the genus.

SWEET WILLIAMS DISEASED.—Specimens badly attacked by Puccinia arenariæ came from Liphook. This fungus attacks Lychnis dioica and several other wild plants, and no doubt spreads from these to cultivated sweet williams. The attacked plants should be burned, and the remainder sprayed with a rose-red solution of potassium permanganate.

British Gardeners' Association.

The usual monthly meeting of the Watford Branch was held recently, when Mr. Fulton presided, and there was a good attendance, being over thirty present. Mr. J. Weathers gave an able address on "Should Women Gardeners Become Members of the B.G.A.?" which brought out a good discussion, and was thoroughly appreciated by all present. The next meeting will be held on October 16, at 7.30 p.m., when Mr. Durrant will read a paper on "Carnations."

OBITUARY.

MR. ROBERT LINDSAY.

We regret to learn of the death of Mr. Robert Lindsay, at Kaimes Lodge, Murrayfield Road, Edinburgh. Mr. Lindsay had not enjoyed good health latterly, and lived quietly since 1896, when he retired from the Curatorship of the Edinburgh Botanic Gardens, a position he filled for thirteen years. Mr. Lindsay was a capable horticulturist, and no mean botanist, his knowledge of alpine plants being peculiarly intimate and extensive, and these flowers he continued to cultivate in retirement. To him we are indebted for some hybrid saxifrages, and for much assistance in the cultivation of these and allied plants. Mr. Lindsay was a prominent and highly-respected member of the various horticultural and botanical societies in Edinburgh.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of The Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of The Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in The Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

PLANTING THE WINTER ACONITE.—E. S. T., Westbury: As an amateur I am asking for your assistance in what is probably a simple or even trivial matter to my professional brethren. In the garden at my old home we had winter aconites in great beauty early in the year, and so there is a sentimental reason, at least, for my desire to have these bright little flowers in my own garden. My difficulty is to know the best time for planting. — September, indeed as early in the autumn as it is possible to obtain the little tuberous roots, is the best time for planting the Winter Aconite. However, do not despair, but purchase a quantity at once, and plant them a couple of inches deep under flowering shrubs such as lilacs and philadelphuses, where these are thinly planted; around tall oak or other spreading trees, and in the grass also, selecting sites readily viewed from the house windows. An occasional top-dressing of old manure, in autumn, will assist these bright spring flowers materially.

DESIGNS AND COLOURS FOR SUMMER AND AUTUMN BEDDING.—M. D., Bucks, who has a great deal of summer bedding to carry out, asks us to recommend him a book dealing with this subject, giving designs, plants to be used, and the colour schemes. He would prefer a book with the designs in colours. We confess our inability to recommend such a book, but shall be very glad indeed if any of our readers have any knowledge of such a publication as our correspondent desires.

BLUE AND YELLOW BORDER FLOWERS.—B. N., Berlin: Will you kindly give me in your next issue a list of blue and yellow hardy border plants, for borders of one colour, at different heights, but not above one yard?—By restricting the height to one yard, the range of subjects is severely limited, and, it seems to us, the effectiveness of such borders must be reduced as a consequence. Further, you do not tell us at what season of the year such borders are expected to be at their best. Serviceable blue flowers for a blue border would include Anemone appennina, A. blanda, and A. Robinsoniana, all about six inches; Campanula barbata, 1½ft.; C. carpatica, 9in.; C. garganica, 4in.; C. latifolia, 2ft.; C. persicifolia cærulea, 2ft.; C. Van Houttei, 2ft.; Dracocephalum speciosum, 1½ft.; Eryngium alpinum, 2ft.; E. amethystinum, 2ft.; Gentiana acaulis, 4in.; G. Andrewsi, 1½ft.; C. asclepiadea, 1ft.; G. septemfida, 1ft.; G. verna, 6in.; Geranium ibericum, 1ft.; Linum narbonense, 2ft.; Lithospermum Gastoni, 1½ft.; Lobelia syphilitica, 2ft.; selected lupins; Polemonium cœruleum, 2ft.; Veronica incana, 2ft.; V. spicata, 1½ft.; Viola cornuta and blue varieties of garden violas. Then there are such annuals as cornflowers, Asperula oriental, 1ft.; nigellas, nemesias, nemophilas, and Phacelia campanularia. The assistance of delphiniums, of the taller campanulas, of several Michaelmas daisies, and of Anchusa italica and its several varieties. Yellow-flowered subjects of merit are Anthemis tinctoria, 1½ft.; A. Kelwayi, 1½ft.; Alyssum saxatile and its variety citrina, 1ft.; Aquilegia chrysantha and yellow garden varieties of the long-spurred section, 2ft. to 3ft.; Arnebia echioides, 1ft.; Centaurea macrocephala, 3ft.; early chrysanthemums in great variety of heights and shades of colour; Chrysogonum virginianum, 6in.; Coreopsis grandiflora, 3ft.; Doronicum caucasicum, 1½ft.; D. austriaca, 1½ft.; Gaillardias in variety; Helenium pumilum, 2½ or 3ft.; German Irises of sorts, 1½ to 3ft.; Lysimachia vulgaris, 3ft.; narcissus of sorts; yellow alpine auriculas; Rudbeckia speciosa, 2½ft.; Solidago Drummondi, 2½ft.; S. lanceolata, 3ft.; varieties of Trollius europæus, 2ft.; violas in variety, and tulips. These by no means complete the lists in either case, but of yellow annuals there are many capital plants, notably the marigolds, chrysanthemums, coreopsis, erysimums, lupins, and œnotheras. Here again we must point out that the limitations of height prevent the use of the helianthuses, the newer tall rudbeckias and heleniums, many solidagos, and chrysanthemums, liliums, etc.

STREPTOSOLEN JAMESONI FOR SUMMER BEDDING.—R. C. D., Isle of Wight: Will you kindly tell me what is the system adopted by the authorities at Hampton Court to obtain such satisfactory results from Streptosolen Jamesoni in beds? This summer I put out plants raised from cuttings last year. These plants were small, but have grown now to be 3ft. or more high, and, as the small plants were pegged down like verbenas, they have now become a mass of foliage. There have been no flowers, however, and at this late date (September 26), flowers can hardly be expected. I have grown Streptosolen Jamesoni for years in a greenhouse, and have had abundance of flowers. Is the secret of success at Hampton Court to be found in putting out large, two-year-old plants?—To ensure a fine effect in summer bedding by means of Streptosolen Jamesoni, it is necessary to have large plants to start with, and those two years from the cutting are quite frequently used. They are started into growth in the spring, and are in flower or just coming into flower when placed out of doors about the first week in June. As such plants are in many cases in fairly large pots, they are sometimes plunged and not planted, and this has the effect of checking exuberant growth, and at the same time induces the production of flowers, but watering and feeding have to be considered regularly if such methods are followed.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

N. M., Chepstow.—1, Cyperus laxus; 2, Cimicifuga racemosa; 3, a variety of Aster amellus; 4, Cypripedium Milo.

A. F., Midlothian.—Two fine blooms of Cymbidium grandiflorum.

J. C. C., Alverstoke.—1, Streptosolen Jamesoni; 2, Physalis Francheti; 3, Symphoricarpus racemosus; 4, Lonicera japonica.

F. J. W., Bristol.—1, Lycesteria formosa; 2, Clianthus puniceus; 3, Lilium neilgherense; 4, Helianthus multiflorus; 5, Artemisia lactiflora; 6, Justicia carnea.

W. H., Woking.—Please send again when plants are in flower. No. 1 is a sedum, No. 2 a stapelia, and No. 3 probably a genista, but better and flowering specimens are necessary for determination.

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, Gardeners' Magazine, as advised in the notice at the head of "Answers to Correspondents."

S. E. C., Aberystwith.—Muscat Hamburgh grape.

E. J. S., Rye.—1, Emperor Alexander; 2, Golden Noble.

T. N., Wolverhampton. — 1, Chelmsford Wonder; 2, Worcester Pearmain.

A. N., Cromer.—1, Fearn's Pippin; 2, Newton Wonder; 3, Bramley's Seedling.

O. F. R., Carnforth.—1, not recognised; 2, Pitmaston Duchess; 3, Dumelow's Seedling.

F. A. G., Swindon.—1, Mère de Ménage; 2, Gloria Mundi; 3, not in character; send again.

B. C., Merton.—1, Bramley's Seedling; 2, Stone's; 3, Beurre Diel; 4, Souv. du Congrès; 5, Beurre d'Amanlis.

J. C. C., Alverstoke.—1, Claygate Pearmain; 2, Lane's Prince Albert; 3, probably a small fruit of Peasgood's Nonsuch; 4, King of the Pippins.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

NEW BOOK.

"BULBS AND THEIR CULTIVATION." By T. W. Sanders, F.L.S. (W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London, E.C.).

The appearance of the second edition of this highly popular and extremely useful work on the cultivation of bulbs, is opportune at the present time, when all who are concerned with garden management are busily engaged in planting the various kinds of bulbous plants that are grown in British gardens, or are making preparations for proceeding with this interesting work. The new edition is also of interest for the direct evidence it affords of the high appreciation of the general body of garden owners of the author's endeavours to assist them in taking full advantage of the aid that the various classes of bulbs are so well able to render in the production of beautiful colour effects. The book is comprehensive in scope, and the cultural details are full and so clearly stated that even the tyro in gardening should have no difficulty in understanding the directions given, or of carrying them out. The selections of the various kinds are sufficient for the various purposes, and afford ample evidence of a thorough acquaintance on the part of the author with all the finest kinds, and a strong desire to assist the reader, whatever may be the purpose for which the bulbs are required.

Statice brassicæfolia. — According to the "Dictionary of Gardening," this shrubby species of statice was introduced from the Canary Islands in 1859, but it would appear to be but little known. It does not occur in the Kew Hand List, but in the greenhouse there it is, and has been for some time, very showy. It belongs to the same section as Statice arborescens and S. profusa, and, like them, should be useful for growing into specimen plants, as well as in smaller examples for greenhouse decoration.—K.

VOL. LVI.—No. 3,128. SATURDAY, OCTOBER 11, 1913.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Size of Vegetables.

Few of the many questions that exercise the minds of horticulturists from time to time have given rise to so wide a divergence of opinion as have those relating to the sizes most suitable for vegetables intended for table use and for competitive purposes at public exhibitions. This difference of opinion may be traced back to the time when the exhibition of vegetables in accordance with modern views was in its infancy, and it is not unreasonable to assume that many years will elapse before it will be possible to obtain a consensus of opinion on all points in connection with the selection of the several kinds for the two purposes referred to. There has been a considerable convergence in the views held by the leading cultivators within recent years, and there is a general agreement that both exhibitors and judges should place a higher value upon the quality of vegetables exhibited than was for a long time the case, and that their size should be a secondary consideration in determining the relative merits of the kinds in competition. As the result thereof there has been a considerable reduction in the sizes of the various kinds, as compared with those which found favour with competitors and those entrusted with making the awards a quarter of a century or so ago. While this reduction has been in progress a general feeling, amounting almost to a consensus of opinion has arisen that practically all kinds may be staged at the exhibitions of a larger size than would be suitable for the tables of those who place quality on a plane considerably higher than that which they would assign to mere bulk. This agreement, while difficult of justification, with a rigid adherence to the view that competitions are of value only for the encouragement of the cultivation of vegetables for the table, has proved a convenience in enabling the judges to make their awards more readily than would be possible were all the specimens limited to table size. Vegetables, when comparatively small, are usually more or less shapely, and differ but little in appearance when shown by various exhibitors, whereas when larger examples are allowed considerable skill is necessary in their production to prevent the development of coarseness, which is a serious defect in vegetables of all descriptions. Whether, because of this convenience in determining the relative merits of products in competition, a size ranging from twenty-five to fifty per cent. in excess of that most suitable for the table should be allowed opens up another question of considerable importance. With reference thereto, we shall not do more than express an opinion to the effect that the closer the approximation in size of exhibition and table vegetables the better for all concerned. The question as to the sizes of exhibition vegetables has become somewhat acute, as a consequence of the disqualification of two exhibitors at the recent vegetable show held by the Royal Horticultural Society. There has been considerable discussion in horticultural circles with reference to the matter, and it appears to have been assumed by some that the Council of the Royal Horticultural Society are endeavouring to effect a decrease in the size of esculents shown at their meetings, and that to enforce their views drastic steps were taken at the show in September last without the exhibitors having been given sufficient notice. In so doing they have been under some misapprehension, for, as we understand the case, a class for nine kinds was, as in previous years, provided for the purpose of obtaining a representation of vegetables that are in general use of a size that is most favoured in households in which the culinary arrangements are under the supervision of a first-class chef. Seeing that a similar class had been included in the schedule of previous exhibitions, and had somewhat failed in its object, it would have been well had the conditions of competition been more explicit, and more fully set forth. Turning to the schedule, we find it simply stated in connection with the class in question that, "The object of this class is to illustrate vegetables which are in daily use and possess the qualities most valued for table use by cooks." This statement was hardly sufficient to meet the necessities of the case, and some reference should have been made to the fact that the real object of the class was to ensure their representation at a stage of development that would admit of their being served whole. It is obvious that pods of runner and French beans ranging from ten to twelve or more inches in length, tomatoes weighing half a pound or more, and other kinds of like proportions, would be unsuitable for the purpose. Not in all households where skilled cooks are employed is this manner of serving vegetables adopted, and, this being the case, it would have been extremely difficult for the exhibitors to clearly understand what was really required of them had they received no information beyond that given in the schedule. It appears, however, that further particulars were supplied, for we learn on good authority that after the exhibitors had sent in their entries they were advised as to the stage of development in which the several kinds must be shown, and the consequences that would follow the staging of products similar

MR. A. C. SMITH.

to those presented at previous exhibitions. It is, therefore, obvious that mistakes were made on both sides, and that, as a consequence, visitors lost the opportunity of seeing at the exhibition vegetables at the stage at which they can be served other than in the manner which finds favour in the greater proportion of households at the present time. It would be a distinct advantage were such classes to be provided in the schedules of the leading societies, inasmuch as the collections in competition would not only constitute a feature of much interest, but they would demonstrate the possibility of considerable variation in the methods of placing upon the dinner table the several kinds of vegetables now represented in British gardens.

Mr. A. C. Smith, estate steward and head gardener to Sir H. B. Samuelson, Bart., Hatchford Park, Cobham, Surrey, is particularly well known in the Metropolitan district by reason of his connection with the Royal Horticultural Society, as its assistant superintendent at Wisley, for six years. Mr. Smith commenced his gardening career under his father, who had charge of the gardens and plantations at Dormont, Lockerbie, Dunfriesshire. After leaving home he spent various periods, as journeyman, at Byram Park, Yorks, the seat of Sir J. Ramsden, Bart.; Brayton Hall, Cumberland; and Petworth Park, Sussex. He eventually became foreman at Ascog House Gardens, in the Isle of Bute, and then secured the post of general foreman at Knighthayes Court, North Devon, the seat of Sir John Heathcote Amory, Bart. Mr. Smith's first post as head gardener was at Eden Hall, the residence of Sir R. G. Musgrave, Bart., where he remained for six years. During the latter part of this period Mr. Smith had the management of the woodlands on the estate, and he was a member of the committee of the Carlisle and Cumberland Horticultural Association. Mr. Smith then came south, and for three years had charge of the Lydhurst Gardens, near Haywards Heath, where Mrs. Mackenzie has a very interesting and extensive collection of flowering trees and shrubs and conifers. While at Lydhurst Mr. Smith was an occasional exhibitor, and on one occasion secured the Silver Banksian Medal of the Royal Horticultural Society for begonias. Mr. Smith left Lydhurst to take up the position of assistant superintendent at Wisley under Mr. S. T. Wright. Here he remained for six years, adding materially to his own renown as a cultivator, and gaining experience of a quite unique character in connection with trials of fruits, flowers, and vegetables. It is not very long since Mr. Smith entered upon his present position at Hatchford Park, but his equipment for his duties is such that he has gained the fullest confidence of his employer.

Ulster Apple Orchards.—Some years since the Ulster Horticultural Society instituted, with the assistance of the Irish Department of Agriculture, a series of competitions among the owners of apple orchards in the several counties forming the province of Ulster. Originally there were two competitions, one for orchards exceeding three acres, and one for orchards not less than one acre or more than three acres. These proved so successful in creating increased interest in the management of apple orchards, and effecting improvements in their management, that two years since a third competition was introduced, this being for orchards exceeding three acres and from four to ten years old. Last year there were four orchards in competition in the last-named class, but this season there were eight, and these were in the counties of Antrim, Armagh, Down, Fermanagh, Londonderry, and Monaghan. In the larger class for old orchards the premier award is the Aberdeen Cup, and in that for small orchards the Gibson Cup is the chief prize. The important task of making the awards was entrusted to Mr. J. Lynas, Moyallen Gardens; Mr. J. Harding, Caledon Castle Gardens; and Mr. W. J. Harding, Fruit Inspector of the Department of Agriculture, and they may be congratulated on the admirable manner in which they performed their somewhat onerous duties. The Aberdeen Cup was awarded Mr. J. Donnelly, Blackwatertown, Armagh; and the Gibson Cup to Mr. J. Moffett, Lisnamintry, Pottadown; while the premier award for young orchards was made in favour of Miss Wright, Desertlyn, Moneymore. The improvement that has been accomplished in the management of the apple orchards since the institution of these competitions is very great, and, as a consequence thereof, their value as a source of profit to the owners has been materially enhanced.

National Rose Society. — This society continues to increase in popularity, and, as the result, new members are being added to the list at a more rapid rate than at any previous period in its history. The present rate in the increase of membership is, we understand, about 100 per month. The society will, in 1914, hold a spring exhibition at the Royal Horticultural Hall, a metropolitan exhibition in the gardens of the Royal Botanic Society, Regent's Park, in the second week in July; a provincial show in the following week at Bath; and an autumn exhibition at the Royal Horticultural Hall in September, the date of the last-named being about a week later than the show held last month.

Horticultural Club.—Following the house dinner of the Horticultural Club, on Tuesday, the 21st inst., Professor W. B. Bottomley, B.A., will give a lecture on "The Effect of Soluble Humates on Nitrogen Fixation and Plant Growth." The lecture will be illustrated with lantern slides, and with living plants showing the good effects of manuring with peat after it has been treated in the manner to be described by Professor Bottomley. The dinner will, as usual, take place at the Hotel Windsor, Westminster, S.W., and commence at 6.30 p.m.

Cause of Colour Changes in Flowers. — Colonel H. E. Rawson, C.B., presented to the Botanical Section of the British Association a paper on "Variation of Structure and Colour of Flowers under Isolation." In this he described certain experiments begun eight years ago in which the method had been followed of shading off with a perfectly opaque screen all direct rays of the sun for certain selected intervals of daylight, while admitting all the diffuse light possible. The garden nasturtium (Tropæolum majus) had been used for the experiments. The new mauve variety obtained in Pretoria by the method of screening, whose seed was brought to England in 1907, and came true, now flowered and seeded freely in any aspect. When any material change had been made in the colouring pigments of the petals the flowers experimented with always showed a marked tendency to be sterile. Sometimes, as the flowers grew, markings on petals had been removed altogether, or, in other cases, intensified and enlarged, so as to suffuse the whole face. Honey guides had been removed. Besides these changes, flowers with a short, blunt spur (a recognised variety), or with none at all, or with two and three spurs, had become common, and were transmitted through the seed. The experiments definitely pointed to a connection between the variations of colour and structure and the sun's altitude, both seasonal and diurnal. There seemed little room for doubt that by this method of screening, which departed but slightly from the conditions to be found in nature, metabolism had been affected, and changes of colour and structure produced which could be reproduced in other individuals. Many instances had occurred of low sun modifying crimson colouring pigments, so that the yellow predominated, and of the highest sun available in these islands promoting the purple and violet pigments. Some red pigments, but not all, could be intensified by intermediate sun.

Perpetual-flowering Carnation Society.—The winter exhibition of this society will be held at the Royal Horticultural Hall, Wednesday, December 3, and the schedule of prizes offered for competition is now before us. There are sixty classes, the most important being the open class for a group of cut carnations, in which the silver cup presented by American florists will form part of the premier award; the open class for twelve vases of blooms, in which the prize is the fifty-guinea silver-gilt challenge cup, presented by Mr. G. Munro, jun.; and the class, open to private growers, for a group of plants of perpetual-flowering carnations, in which Lord Howard de Walden's silver-gilt challenge cup will be the principal award. On the same day Mr. G. H. Lawrence will give a lecture on "Carnations for Amateurs," at 3 p.m., and at 6 p.m. the annual general meeting of the society will be held. The lecture will be given and the annual meeting held, in the Lecture Room of the R.H.S. Hall.

An Interesting Competition at Olympia.—An interesting position has arisen in connection with the Ideal Home Exhibition which opened at Olympia on Thursday last. A fifty-guinea cup was offered to the firm which laid out the best garden on a very limited site such as would be available in a very small area at the back of a house in a congested town district. The task of beautifying such an unpromising site is obviously very difficult, a fact that was, evidently, fully appreciated by the general body of garden makers, for only two firms entered into the competition. In the circumstances the authorities offered to divide the value of the cup between them, but this offer was not accepted, as both firms—Messrs. J. Carter and Co. and Messrs. J. Cheal and Sons—preferred to have the merits of their arrangements determined in the usual way. Sir Albert Rollit was accordingly invited to act as judge, and this invitation was accepted on the condition that if he was in any doubt in the matter he should call in two members of the Councils of the Royal Agricultural Society and Royal Horticultural Society to assist him, in which case the final decision is to be by a majority.

Plants as Rock Builders.—In Sir Archibald Geikie directed attention to the important position occupied by the calcareous algæ in the formation of limestone it was generally assumed by geologists that the limestone deposits were of animal origin. The eminent geologist, Professor E. J. Garwood, has recently made further reference to these lowly forms of plant life with a view to stimulate further interest in them as rock-builders, and the influence they have had in modifying the face of the earth, and in affording supplies of lime that are of immense value to cultivators. Only two British genera of these plants have as yet been described from the

rocks of this country, but Professor Garwood considers that there are several other forms from British rocks that will ultimately be included in the group With reference to the conditions which probably obtained during the growth of these limestone-forming plants, it is suggested that the oolitic deposits and dolomites, with which they are closely associated, accumulated in wide lagoons, similar to those which now exist in the neighbourhood of coral reefs, and in sheltered, submerged plateaux as may be found at the present time in the Bay of Naples. The general conclusions of Professor Garwood are that during the periods at which these growths took place there was considerable elevation or subsidence of the land areas.

Export of Potatoes to America.—The Horticultural Board at Washington has decided to continue indefinitely the quarantine against potatoes from Great Britain, Germany, Austria, Newfoundland, St. Pierre, and Miquelon, notwithstanding the request of the British Board of Agriculture that the quarantine on Great Britain should be raised or modified.

Lawes and Gilbert Centenary Fund.—Next year (1914) is the centenary of the birth of the late Sir John Lawes, and 1917 is that of the birth of Sir Henry Gilbert, and it is proposed to celebrate the occasion by erecting a suitable Commemoration Laboratory at the Rothamsted Experimental Station, which these distinguished agriculturists founded. For this purpose the sum of £6,000 is required to be raised by public subscription. Everyone interested in agriculture and horticulture owes a debt to the work of Lawes and Gilbert at Rothamsted. It was they who first demonstrated in this country the value of artificial manures, and their experiments, more than any others, showed what these could do, and how they should be used. The Rothamsted Field Experiments have become the model on which practically all others are based. They carried out experiments on almost all branches of agriculture, and obtained results of the greatest value to cultivators. The Rothamsted Laboratories are further famous as the place where two other distinguished scientists have worked. Here it was that Professor Warington did so much for Agricultural Chemistry and Mr. A. D. Hall carried out researches that will long continue to bear fruit both at home and abroad. The changes that are gradually taking place in cultural methods make it more urgent than ever that the Rothamsted work should continue to expand. The present laboratories are not adequate for this new work, and it is proposed to build and fit the new Commemoration Laboratory. It is most desirable that horticulturists should assist, especially as when £6,000 has been raised by public subscription a similar sum will be given from the Development Fund. The sum of £12,000 will suffice for the provision of a laboratory adequate for all purposes. Those who desire to contribute should communicate with The Secretary, Rothamsted Experimental Station, Harpenden.

Action of Bordeaux Mixture.—In a paper contributed by Professor Barker and Mr. C. T. Gimingham to the Agricultural Section of the British Association on the action of Bordeaux mixture, the authors stated that their experiments had shown that germinating spores and the thin-walled cells of fungus hyphæa, when in contact with or within a limited radius of particles of the copper compounds of the spray fluid, exercised solvent action, and were killed by absorption of the dissolved copper.

OCTOBER IN THE ROSE GARDEN.

Judging from the general appearance of roses at the autumn show of the National Rose Society, I fear many of my friends are not so well off for rose blooms as we are in East Sussex. We have never had a more pleasing outlook for October, and, with the greater profusion of good autumnal bloomers now available, our beds are really gay. To name the varieties would occupy much space, for most of the free-blooming hybrid teas and teas, together with the dwarf polyanthas, are one mass of blossom, and with quite clean foliage.

In a summer note I mentioned a number of perpetual-flowering climbers and pillar roses. I would like to add that Climbing Liberty, Climbing Orleans Rose and Climbing Richmond are great acquisitions, and there is no need to grow such a lot of our extra vigorous varieties, which only carry one good crop of blossom each season. I think it was in the issue for July 12 that the few notes referred to appeared, and I would like to remind intending purchasers of the varieties then mentioned.

One cannot have a better time than the present for preparing ground intended for roses, and I would not delay longer than can be avoided. Freshly-prepared ground is all the better when it has had time to settle down a little and, unless ready, one's rose plants are not always put in so promptly as many desire.

SYMPHORICARPUS MOLLIS.

Fruits relatively large and pure white. F.C.C., R.H.S., October 7, Hon. Vicary Gibbs, Aldenham House, Elstree.

Where plants have been, or are still, suffering from mildew, red rust, and black spot, which I fear have been rather prevalent this year (if one is to judge by the numbers of queries I have received relating to these diseases), it will be wise to collect and promptly burn all fallen leaves as soon as possible. There can be no doubt that these fallen and affected leaves will spread diseases next season as soon as weather conditions and young growth favour their development once more. There can be no material benefit from rose foliage as a future plant food, so it is better to collect and burn it.

Examine and be prepared to house pot roses at any time now, for bad weather so often comes unexpectedly, and causes a confusing rush of work if one is not duly prepared. Our maiden standards are in full growth and flower. Mdme. Abel Chatenay, Hugh Dickson, Lady Hillingdon, Lyon Rose, Sunburst, Edu Meyer, Caroline Testout, Marie Van Houtte, G. Nabonnand, Mrs. Aaron Ward, Gen. McArthur, and Peace are very gay with blossom, and as bright as at any time this season. Rosarian.

THE NATIONAL ROSE SOCIETY.

Beginning in quite a small way, the National Rose Society has so grown in numbers and developed in operation as to become the one recognised authority on all matters relative to the rose. With increased membership comes increased responsibility, and the question has arisen—Can the society be made still more useful, and that, not only to its own members, but to all who love and cultivate the rose?

There was a period when the National Rose Society confined its attention solely to the organising and holding of exhibitions, but at the present day its efforts are extended to the issuing of publications which should be of valuable assistance to rosarians throughout the United Kingdom. In this respect, as in others, the aim of the society is to inform, to instruct, to focus, and if this is to be efficiently carried out, the society's perspective should be as broad as its membership, and as wide as its title—national in its knowledge, national in its helpfulness. Is there here room for improvement? Is there a danger lest it should fail to fulfil its aims, and so failing, subside into a Southern Counties Rose Society? Let us consider.

The National Rose Society acts through an elected council, from which body standing committees are formed for the purpose of dealing with specific departmental work, and it is obvious that each committee should be in full possession of all facts relative to the subject with which it has to deal. But consider the composition of the council from which committees are formed. The council meets in the Metropolis, and it is essential that its members should be more or less regular in their attendance. Indeed, a record of individual attendances is tabulated, and published at the close of the year, preparatory to the next election. It is, therefore, evident that residential proximity to the Metropolis is an important factor in the composition of the council, with the result that a large majority of its members—nearly all in fact—reside within the Metropolitan area or, at least, in the home counties. But the society claims to be national.

To illustrate this point, let us consider the official catalogue of roses, in which is not only an extensive alphabetical list of roses, with a brief description of each variety, but also several lists of roses recommended for various purposes. It is well known that the quality and habit of a particular rose varies considerably according to the locality in which it is cultivated. In support of this we have only to look at the many roses emanating from Ireland, which, although they were each awarded the gold medal when first exhibited, have been discarded as unsatisfactory by growers in England. Some varieties that flourish in Ireland are poor in the South of England, and vice versa. The writer has visited rose gardens in the south as well as the north of Ireland, and seen varieties flourishing, and, therefore, highly esteemed by their growers, which we in England consider hardly third-rate, and have ceased to grow. And the same may be said of Scotland.

If the committee which prepares the official catalogue is limited to residents in the South of England, can its members have a personal knowledge of the value of a particular rose for growers in Scotland and Ireland; can they, except from report, give adequate advice to growers in these districts?

Now one is perfectly certain that it is the earnest desire of the Publications Committee to make their publications as helpful as possible to all members of the N.R.S. in whatever locality they may reside. But how can this be accomplished? Surely by ascertaining the views of growers as widely dispersed as the membership, so that the catalogue or other publication should help, not only the rosarians of England, but also those of Scotland and Ireland. In a word, it should be a national official catalogue. In the way that this should be done two methods suggest themselves, namely, (1) by the appointment of official correspondents or (2) by a District Committee having advisory, but not executive, powers. The first method, adopted, one believes, in France, has this inherent weakness—it depends for its efficiency in execution upon the knowledge and efforts of an individual. The second is free from such weakness; the body is summoned, members consult together, and, after the opinion of the members has been crystallised, the advice sent to the council carries more weight than if it came from an individual.

It may be asked, is there any real need for this? Well, it has been the privilege of the writer for some years to visit rose shows in an official capacity both in Scotland and Ireland. Here he has seen great gatherings of keen rosarians—one of them met this year was a miner from the pit showing a twenty-four—and also many beautiful varieties that are seldom grown now in the South of England. It is surprising, however, to find how few of these exhibitors belong to the N.R.S.; how small is the influence of the society. And one of the causes is this—the publications of the society, especially the catalogue and pruning book, do not materially assist them, and this question has on more than one occasion been put to the writer: "What practical benefit shall I derive by joining the N.R.S.?" The miner mentioned above remarked, "You in the South of England like Florence Pemberton, but I have to grow it under a jam jar." So let us try to meet the requirements of all rose growers in the United Kingdom.

A few weeks ago "conversations" took place—an informal meeting of a few rosarians was held just for interchange of ideas on this point. The meeting was composed of two growers from Scotland, two from Ireland, together with some Vice-Presidents, two southern trade growers, and the honoured secretary of the N.R.S., Mr. Mawley, and, without going into details here, we may state that it was agreed without one dissentient that the matter was worthy of the consideration of the council of the N.R.S. The plan suggested was that District Consultative Committees should be appointed for Scotland and Ireland, and, if possible, for the North of England as well. The Irish and Scottish growers mentioned names of those who might be willing to serve on their respective committees. For Ireland, it was thought the Irish Rose Society might act; in Scotland leading trade and amateur growers were prepared to move. But they one and all impressed upon the meeting the desirability of undertaking something on the lines indicated in order to extend the influence and efficiency of the National Rose Society, and the writer of these notes was deputed to bring the case before the council.

SUCCULENT PLANTS FOR AMATEURS.

(Continued from page 619.)

Euphorbias.

The genus Euphorbia is one of the largest in the vegetable kingdom, and includes a large number of succulent species. Most of these are natives of tropical and sub-tropical Africa, India, Madagascar, Canary Islands, and Mexico. Nearly all the species in cultivation are African, and thrive in a warm, sunny greenhouse. They contain a virulent poison in all their parts, and on this account are not recommended for window culture. They should always be handled with caution, and any wound made by their sharp thorns should be immediately washed. Several cases of badly-poisoned hands and arms have come under my notice during the past fifteen years caused by slight scratches from these plants. There is, however, no need for alarm, providing the most ordinary care is taken when handling them, and I have personally handled many hundreds of plants without any serious injury. The succulent species present a most extraordinary amount of diversity in the shape and size of the stems, and many are very beautiful and symmetrical.

Most of the euphorbias possess thorns of some kind, the arrangement of these on the stems being the means of dividing the genus into well-marked sections. Many of them greatly resemble some of the cacti in their general appearance, but botanically are widely separated. A selection for all purposes may be made from the following: E. triangularis, with erect, roundish leading stems, and triangular lateral branches. E. canariensis, E. lactea, and E. heterochroma are dwarf, bushy species, with four-angled stems, and E. abyssinica, E. Hermentiana, and E. candelabrum are tall, tree-like species, also with square stems. E. pentagona usually has five-angled stems; E. heptagona and a few other species, with six-angled stems, while those with eight-angled stems are common and include such well-known species as E. cereiformis, echinus, mamillaris, meloformis, and Beaumeriana. A section of the genus have dwarf, gouty, leading stems, and long or short slender lateral growths; an example of this kind is the well known E. Caput-Medusæ. Many species again have round (terete) stems and branches; these vary in size considerably. Examples of this class should include E. balsamifera fanalis, Tirucalli, mauritanica, and Bertheloti. Two old garden plants of this genus are the well-known "Poison Thorn." E. splendens, and its near ally, E. Bojeri, the stems of which are densely clothed with dark brown or black thorns. Both are quick-growing species, and of trailing habit, and are usually grown trained on balloon-shaped wires, or near the glass as a climber. Their charm lies in the large numbers of bright crimson or red bracts and flowers, which are produced during early spring and summer. The flowers of most of the succulent species are inconspicuous, and of no great beauty.

C. P. Raffill.

(To be continued.)

TUFTED PANSIES.

Despite the many vicissitudes through which gardening has passed during the last decade or two, tufted pansies have ever received recognition as being among the most meritorious of garden plants. They combine the tufted habit and hardy nature of the alpine viola with the rich and varied colouring of the pansy, and it is the union of these qualities that make them so desirable in the garden. They succeed under varied conditions, and on a great variety of soils. Of the latter, those rich in humus, and having a high percentage of calcareous matter, produce the best and most lasting results with tufted pansies, while soils deficient in these substances should have an edequate supply introduced before planting, and the ground should be deeply trenched wherever practicable.

The humid atmosphere of the northern counties fosters the development of the tufted pansy to a remarkable degree, consequently it is there that it appears prominent in every scheme of garden decoration, and from this source many varieties of outstanding merit have emanated. In the southern counties, with drier air and more powerful sun, it is often difficult to maintain such a high level with tufted pansies during the summer months. They are surface-rooting subjects, and the roots form a perfect network of fine fibres that soon exhausts the soil, so that during the hottest periods it is essential to supply some rich surface dressing, augmented by supplies of water, both clear and in the form of liquid manure. It is also of assistance to the plants if all spent flowers are removed at an early stage, as the strain of seed bearing militates against their flowering.

Provided the soil is brought into proper condition tufted pansies will practically succeed in any position, except under dense shade; planting may be carried out at almost any season, if ordinary care is taken to follow up with mulching and watering in dry weather. The months that give the best results in planting violas are October and March. The former guarantees an early spring display, and the latter gives similar results during the summer months. Tufted pansies are readily propagated by seeds, cuttings, or division. The latter gives excellent results in ordinary garden decoration, the flowers are most numerous, but never of the largest size. Such a method entails little expense in time or labour. Cuttings give the strongest plants and largest flowers. They are usually inserted in July or October. The earliest date gives stock for planting in October for a spring display, while cuttings inserted during October are not placed in their permanent quarters before March. This, and division, are always practised when the variety is required true. Seeds from tufted pansies germinate freely, and may be sown any time during the growing season, either in frames or in the open ground. The resulting plants vary to a considerable degree, so that this method of increase is almost entirely adopted for the raising of new varieties. The ranks of the latter are also occasionally added to by older varieties sporting to a different shade.

Tufted pansies are distinguished by having either rayed flowers, when finely-pencilled lines radiate from the centre, or rayless flowers, when these lines are absent. The former have a particularly smart and attractive appearance on the exhibition table, but I think the latter are the most effective in garden decoration. The varieties of the tufted pansy are extremely numerous, and all but the hardiest should be eliminated for garden decoration. Other features of scarcely less importance are dwarf habit, and close, dense growth, so that when in flower the plants present a close carpet of colour. The practice of planting tufted pansies as an undergrowth to roses is one of the most effective arrangements that has lately sprung into prominence. Not only does it solve the problem of the bare soil that detracts from the roses, but the soft contrasts of colour that are readily found are instinct with fresh beauty when associated with roses, and, incidentally, it illustrates that art whereby the most commonplace garden may readily attain to the foremost rank, and results we formerly approached with diffidence now receive full measure of unstinted admiration.

A good selection of bedding violas include: Ardwell Gem, primrose; Ariel, lavender; Bullion, yellow; Blue Cloud, white ground, suffused blue; Blue Bell, violet; George Palmer, golden yellow; Jubilee, dark blue; J. B. Riding, deep mauve; Glencoe, mahogany; Isolde, yellow; Kingcup, deep yellow; Kitty Bell, lavender; Lady of the Snows, white; Marchioness, cream self; Mrs. Allsop, bluish-mauve; Royal Scot, blue; Mrs. Swettenham, rich lavender; William Hill, rose; W. H. Woodgate, soft lavender; and White Empress, white.

THOS. SMITH.

Coombe Court Gardens.

AUBERGINES.

The varietal forms of Solanum melongena provide variously shaped and variously coloured fruits, and consequently there are numerous popular names, such as Egg Plant, Aubergine, Jew's Apple, Mad Apple, and Brinjal, the latter being a title very commonly used in the East; while at home and on the Continent, especially in France and Spain, Aubergine is the most common appellation.

So far aubergines are not very well known or understood in this country as articles of diet, but when their culture is better understood, and a taste for them has been acquired, they may prove scarcely less popular than the allied tomato. As an autumn vegetable the aubergine makes a very interesting and pleasing change from the ordinary kinds.

Unless especially early crops are needed, the best time to sow seeds is during March or April. Thin sowing in pots or pans, in moderate heat, is a good plan—indeed, early treatment follows upon the lines usually laid down for tomatoes—but the great point is to secure sturdy, stout growth. For the seedlings 60-sized pots will suffice; and good loam, leaf-soil, and sand will provide a suitable compost. Larger pots must be subsequently used,

AUBERGINE PURPLE TOKIO.

One of the finely-fruited aubergines shown by Mr. G. Cradduck at the R.H.S. meeting, September 23.

and spent mushroom-bed material and good loam form an excellent compost for the aubergines to fruit in.

A moderate or intermediate temperature should be provided during the earlier stages of growth, ventilation being increased as the plants grow and as the weather permits, until during July and August a house that is thrown wide open day and night will provide the right conditions. Stop the leaders at six inches high, and when the plants are placed in their fruiting pots, of 8in. size, provide a stout 4ft. stake for support. It may be necessary, and it is always advisable, to pollinate the flowers to secure a good set of fruits, just as is done in the case of early tomatoes. In some seasons, however, there is no difficulty in obtaining a "good set."

The best aubergines for cooking are Perfection and Early Long Purple, but Purple Tokio is a very heavy cropper; and other good varieties are Purple Pekin and Purple Pear-shaped. The white-fruited varieties are not considered so good as the purple ones for cooking. For culinary purposes the fruits should be gathered when they have attained full size, but before the seeds commence to form.

Greenfly is sometimes troublesome, but red-spider is the worst enemy the aubergines have to contend with under cultivation, because it is not easy to provide sufficiently moist atmospheric conditions by means of the syringe, etc., and at the same time secure a good set of fruits. It is during the flowering period, and when the fruits are setting, that special care must be paid to keeping the foliage clean and healthy; and, of course, when the fruits are attaining full size a drier atmosphere is again desirable. However, with a knowledge of these peculiarities, and ordinary care, aubergines may be grown readily and in quantity. From a decorative point of view aubergines are not to be despised, and the interest taken in the group staged seems to prove that Colonel Lockwood is quite right in believing that if fruits are exhibited occasionally they will become popular.

G. Cradduck.

Bishop's Hall Gardens, Romford.

AUBERGINE PURPLE PERFECTION.

A well-fruited example shown by Mr. G. Cradduck at the R.H.S. Meeting, September 23.

Franciscea calycina. — Having completed its growth, this lovely flowering plant may be placed in a warm greenhouse, and be kept rather drier at the roots until shortly before it is required to bloom, when it may again receive stove conditions. Plants rooted in spring may be kept in the stove, but many flowers cannot be expected of them; they will commence to grow early, and if potted and occasionally pinched will be useful for next season.—H. Prime.

CHRYSANTHEMUM NOTES.

Intending exhibitors will now be very busy getting their blooms finished for the shows. With the new exhibitor the work will be done with much anxious thought. No doubt many beginners will have closely examined the classes in the schedules, and marked a number in which to enter.

I do not wish to damp the spirits of new exhibitors, but rather to encourage them in their efforts. It is often the case, however, that, as the actual dates of the shows approach it will be found very inadvisable to fill all the classes marked. In some instances the classes may all be filled simply because the blooms are good enough.

The Treatment of Forward Blooms.

The greatest difficulty experienced in regard to early-developed blooms is that of keeping the outer petals fresh. Where blooms of the incurved section are concerned they are often greatly improved by the removal of the coarser outer petals, whereas the blooms of the Japanese section are dwarfed, and lose their chief characteristic by this course of procedure.

When dealing with blooms of both sections the cultivator should carefully examine the outer petals, and, if they are beginning to fade, remove them forthwith, as if left they would be too much decayed to show, and also they would have had time to contaminate other petals which would have remained sound.

Shading the Blooms.

Begin to shade forward blooms in good time, as if once they begin to lose colour and freshness they will soon become worthless for competitive purposes and for vases in the dwelling-house. The best way to apply shade is to put on scrim, paper, or mats early in the morning, long before the sun's rays fall on the flowers, then burning and damping will be avoided to a great extent. Such shading material should be entirely removed after the sun has set, as the exposure to the light will tend to keep the petals firm. As darkness comes place sheets of paper over the flowers, inside the house, and about twelve inches above them, to prevent moisture settling down on the petals.

Feeding and Watering.

All plants bearing blooms more than half developed must have clear water only. Liquid manure must not be given, and only in cases where the centres of backward blooms require developing should a little nitrate of soda or sulphate of ammonia be applied.

Often enough, a great mistake is made in trying to force open backward flowers by giving them very strong doses of nitrate, ammonia, or other concentrated stimulants. Keep the temperature of the house a little higher, and group the plants in a sunny position, only shading the blooms for an hour or so when the sun first shines on them. Although bronze, chestnut, and yellow and bronze colours fade more quickly than clearer colours, such as yellows and whites, the latter show up specks caused by excessive damp and cold draughts more. Keep all doors of glass structures closed now, and depend mostly on the top ventilation for air.

Suckers.

The rarer varieties are generally very shy in producing cuttings, and where this is the case the young shoots from the base, and even the base of the stem of the plant, should be preserved. The time soon comes when cuttings must be rooted, and then it is satisfactory to be able to cut some really good ones for the purpose.

George Garner.

AN AUDIT OF GRAPES.

Those who saw the fruit show held recently by the Royal Horticultural Society at Vincent Square will readily agree that the grapes there shown were most creditable, and, taken as a whole, superior to any seen at a similar show for some years.

The varieties covered a wide range, and this gave one an opportunity of inspecting many varieties that are not generally grown by the cultivators of the luscious grape. Eighteen varieties in all were staged, which proves that some growers still have sympathy with some of the older grapes which, in the opinion of some, are useless in point of high quality. That gardeners as a body are distinctly in favour of much variety cannot be denied, as they find variety interesting, if not profitable.

When the list I have compiled is examined, it will be found that many grapes that I regard as superfluous—as, for example, Gros Guillaume—are sparsely represented as compared with desirable sorts like Muscat of Alexandria or Madresfield Court.

Muscat of Alexandria heads the list by a long way; and, when we consider that this has not been an ideal season for colouring grapes, the specimens staged throughout were really very fine. Perhaps the berries were a trifle small. The second prize pair of bunches ran the premier exhibit closely, and were the result of inarching the Muscat on to Foster's Seedling, a practice which has been eminently successful for many years. One vine so treated has this year, under Mr. Allan's supervision, produced over 130 bunches. On this stock the berries set easily, the bunches are compact, the colour is of a pleasing amber tint, and there is an absence of shrivelling in the skin.

Very fine were many of the examples of Madresfield Court. The berries in nearly all instances were rather small, but the premier exhibit in the special class was an exception, as the bunches were shapely, with fine berries and colour. How much better it is to grow an extra rod of this grape than encourage such coarse varieties as Gros Maroc, or even Alicante! Black Hamburgh was staged in really superb condition, and especially when we consider that late September is not the best time for this grape. The exhibits still further proved what a valuable grape this is.

It would be difficult to find finer examples of Muscat Hamburgh than those staged by Mr. Goodacre; yet how strange it is more do not grow this, the best-flavoured grape in existence. What could be more meritorious in bunch, berry, or colour than those noted? Yet in not one garden in fifty do we see a vine of it! Gros Guillaume was finely shown by Mr. Barker, each bunch being about 6lb., of much symmetry, fine berry and finish; but, alas! the flavour is but third-rate.

Appley Towers was finely shown several times, the bunches of full size, with medium, well-coloured berries. This grape should be more grown than it is, as its good quality and late keeping properties warrant its extension. At Windsor Mr. McKellar thinks highly of it for late use. Alicante was staged in goodly numbers. The bulk of the bunches were of medium rather than large size; while most of the berries were undersized for that variety, which at its best is not of high quality. As an amateur's grape it is all very well, being of easy growth.

The class for Mrs. Pince contained one pair of handsome bunches, fully 14in. long, with perfectly-finished berries, such as would have pleased the late Mr. Meredith, who showed this variety in the highest condition some thirty-seven years ago. Prince of Wales, a sport from the former, was staged quite indifferently. Somehow this fine grape does not make much headway, and gardeners do not seem to grasp its cultural requirements.

It is seldom we see Buckland Sweetwater so good as it was shown on this occasion by Mr. Barker. The berries were evenly disposed over full-sized bunches, and were beautifully coloured. Lady Downes is not a popular exhibition grape, for as a rule the bunches are not large enough, but in spite of that it deserves more extended culture than it receives, as it is easily the best keeping black grape we have of any quality. Calabrian Raisin was represented by two bunches, weighing not less than 5lb. each; and, although the berries were of good size, they carried that objectionable white, dust-like appearance so characteristic of the variety. Lady Hutt was represented once, and, although of undoubted quality, growers prefer Muscat of Alexandria.

Except as quite an early ripening variety Foster's Seedling is not much grown; consequently was but once staged, and in moderate quality. Mrs. Pearson and Golden Queen were staged once each. The former is free bearing, sets freely, and gives a heavy crop, which, if ripened in strong heat, is of good flavour.

Variety.	Bunches.
Muscat of Alexandria	44
Madresfield Court	18
Alicante	18
Black Hamburgh	14
Gros Maroc	10
Appley Towers	8
Muscat Hamburgh	8
Gros Colmar	6
Lady Downes	6
Mrs. Pince	6
Prince of Wales	4
Buckland Sweetwater	2
Gros Guillaume	2
Golden Queen	2
Mrs. Pearson	2
Calabrian Raisin	2
Lady Hutt	2
Foster's Seedling	2
Total Bunches	156
Total Varieties	18

Swanmore Park.

LARGE ONIONS.

Probably the most important item in connection with the cultivation of fine onions is the preparation of the soil. This should be dealt with in autumn, and the soil must be worked 2ft. deep—3ft. is better—and given a good dressing of manure. I use equal proportions of cow and horse manure, with soot and wood-ashes. As the work proceeds, the surface soil should be left as rough and uneven as possible, so that frost and wind can pulverise and sweeten it.

The best time for sowing seeds is about the middle of January; if sown earlier, I find the seedlings become drawn and weakly. A suitable compost consists of about three parts fibrous loam to one of leaf-mould passed through a ½in.-mesh sieve, the rougher portion being placed in the bottom of the pans or boxes prepared for seed-sowing. After the pans are filled with the compost a gentle watering is given. I sow the seeds thinly and evenly, cover them with fine soil, and place near the glass in a temperature of about 60 deg.

A FINE CROP OF AILSA CRAIG ONIONS.
Grown in Finstall Park Gardens.

The seedlings are pricked off into pots or boxes when large enough to handle, and grown freely until about the beginning of April, when I begin to gradually harden them off, and finally plant out about the end of April or early in May, according to weather conditions.

Previous to planting I give the onion plot a good dressing of soot, and several successive applications are afforded during the growing season. I find this is a sure preventive against the onion grub. If extra large bulbs are required, they should be fed with liquid or artificial manure (Webbs' Special Compound is splendid) from about the middle of June to the beginning of August, and the bulbs should be in a fit condition to be pulled and dried by the beginning of September.

By following these methods I have been particularly successful with onions, and send with this note a photograph of our onion bed. The bulbs were large and shapely, and many exceeded 2lb. each. The variety is Webbs' strain of Ailsa Craig.

Ernest Avery.

Finstall Park Gardens, Bromsgrove.

DAFFODILS IN THE GRASS AT DALHOUSIE CASTLE.

Daffodils never appear to greater advantage than when naturalised in grass, and there is no doubt that this is the most artistic way of treating them. Where space is ample, the larger the masses the more effective are they, but it does not follow by any means that effective arrangements cannot be secured in more restricted areas, nor should even the possessor of a villa garden despair of having at least a few odd corners and suchlike spots utilised in this way. Collections in beds are, of course, very fine, and it is the only way in which it is advisable to grow some of the newer and choicer kinds until their properties for naturalising are tested; but such arrangements are always more or less formal, and do not present such pleasing effects as when they are planted in their natural setting.

At Dalhousie Castle, the residence of C. W. Cowan, Esq., who is one of the most enthusiastic and extensive cultivators of the plant in the country, and where the accompanying photograph was taken last spring, daffodils have been naturalised on a very extensive scale, and some very fine effects have been obtained. Dalhousie Castle stands on the right bank of the river Esk, and the soil is a rather heavy loam, which, judging from the way the plants thrive, seems to suit their requirements very well, while the situation is an extremely suitable one for effective treatment.

Many kinds have been tried for naturalising here, and appended is a list of the varieties which Mr. Pirie, Mr. Cowan's head gardener (who is also an enthusiastic grower as well as raiser of narcissi, and some of whose seedlings are very fine indeed), has found to adapt themselves best to naturalising, and they are so inexpensive as to be within the reach of all. Of course, some of the kinds mentioned may not suit all soils and situations (for example, Horsfieldi has failed to establish itself in Princes Street Gardens, Edinburgh), and, on the other hand, there may be varieties which do not succeed at Dalhousie which might grow very well elsewhere; but the number of varieties which Mr. Pirie has found to do well at Dalhousie is large enough to meet almost any case.

In the planting of the bulbs some care is necessary. Lifting the turf in patches, and laying the bulbs underneath it, does not give them a fair chance, more especially in the case of large bulbs. Making holes with an iron rod is also objectionable, as it compacts the soil too much round the bulb, and does not leave a kindly medium for the roots to penetrate. The implement which Mr. Pirie has found to give by far the best results is Barr's bulb planter. By means of this implement a circular hole is cut out of the turf to the desired depth, the plug of soil contained within the cutter being released in the operation of forming the next hole, and, after a portion of the soil corresponding to the depth of the bulb has been removed, is ready for insertion therein. By means of this implement Mr. Pirie has found that one man cutting holes can keep four men at work planting.

The following are the daffodils found most useful for naturalising in the grass at Dalhousie Castle:—

Trumpet varieties.—Alice Knight, Duke of Bedford, Emperor, Empress, Glory of Leiden, Golden Spur, Horsfieldi, J. B. M. Camm, Madame de Graaff, Madame Plemp, Mrs. Thompson, Obvallaris, Queen of Spain, Scoticus, Victoria, and William Goldring.

Incomparabilis varieties.—Beauty, C. J. Backhouse, Frank Miles, Gloria Mundi, Gwyther, Lucifer, Queen Sophia, and Sir Watkin.

Barri varieties.—Conspicuus, Firebrand, Flora Wilson, and Mrs. C. Bowley.

A COLLECTION OF CHOICE DAFFODILS AT DALHOUSIE CASTLE,
Growing in the Walled Garden.

Leedsi varieties.—Albatross, Duchess of Westminster, Katherine Spurrell, Mountain Maid, Seagull, Waterwitch, and White Lady.

Other good varieties are Poeticus ornatus and the double daffodils, Argent and Telamonius plenus.

A. D. Richardson.

Edinburgh.

Figs.—With very few exceptions, the crops of ripe figs will now be over, so cleaning and maturation of the wood must receive attention. Early trees in pots or tubs should soon be placed under protection, and the pruning must be done at once. Very little pruning is necessary, as by bending down the shoots, heavy cropping, and summer pinching, grossness is soon reduced. Cleanse and paint the houses, wash the trees, and also wash the walls with hot lime and sulphur where scale or mealy bug has been troublesome. — F. Jordan, Warter Priory Gardens.

IBROX HILL GARDEN, GLASGOW.

Annually the citizens of Glasgow have some additions made to their sources of pleasure, as derived from the public parks and gardens. Within the last two or three months the old walled garden belonging to Ibrox Hill House, and now included in the Bellahouston Park, has been opened to the public after having been laid out and planted for the purpose. The garden is of large size, and is surrounded by high walls, which, when fully clad with climbing plants, will not only give shelter, but an added beauty to the flowers with which the garden is filled.

On entering by the main entrance we find on either side beds of good ferns arranged in borders in front of the walls flanking the gateway. These look highly attractive, the ferns being planted in groups, with stones between. Many choice ferns are to be seen here, including unusually beautiful varieties of athyriums, scolopendriums, etc. Another pretty feature of the garden is a bed of heaths of various kinds, planted among stones, and comprising an unusually good selection, among them being the new varieties of Erica carnea.

In another border we find a large variety of the best dwarf-flowering shrubs, these being likely to prove a popular and useful class of subjects for the public taste. Large numbers of phloxes are also cultivated, and among them we noticed as some of the best the following: Hercule, the fine white Meteore, the lovely Mary Campbell, soft pink with white eye, Baron von Deden, Regulus, Henri Farman, Selma, Gruppen Konigin, Fanny, La Mahdi, and a number of others.

Violas are greatly appreciated, and are planted in groups, and along some of the edgings. Among the many varieties one observed Bertha, a fine white; the old, but good, yellow Bullion; Archie Grant, and a number of others. They are doing well at Ibrox Hill. Some good pentstemons are used in groups, and among them was a capital bedding white one, called Countess of Strathmore, which, though not the largest white, is so free and good that it deserves greater favour. It is largely employed in Glasgow parks. Newbery Gem, Southgate Gem, and others are also grown. Sweet peas are cultivated in good groups, and add much to the appearance of the garden. They are very fine here—as good as any the writer has seen this year. Herbaceous plants are not forgotten, and are supplemented by some good annuals. There is a fine variety of the perennial asters with chrysanthemums of the type of King Edward, and others of the same class, veronicas, pyrethrums, and other flowers of worth.

Early chrysanthemums are an impressive sight. There are thirty-six varieties, in lines of one variety, and thirty-six plants in each row. They are very finely grown, and made a grand feature to all admirers of these useful and beautiful autumn flowers. Roses are a feature of this garden, and good pergolas or arches have been erected over some of the main paths. They are of substantial construction, and, unlike too many now erected, have a sufficient span to prevent interfering with the plants beneath on either side of the path. A capital collection of Wichuraiana and other ramblers is planted, and these are doing well, though they have not had time to cover the archways with their beautiful foliage and charming flowers. Another feature of this garden is the group of Polyantha and other dwarf roses. To show the varieties which constitute such a delightful feature one may say that they include Baby Tausendschon, Madame Norbet Lavavasseur, Jessie, Gloire des Polyanthas, Ducher, the old Crimson China, Cramoisie Superieure, Engène Beauharnais, Clothilde Soupert, and others of approved quality. Other roses also receive a full share of attention.

Some good hollyhocks were also noted, and a most pleasing plant observed among the border and bedding plants was Calceolaria Mrs. Gladstone, which was raised by a Vale of Leven amateur. It is hardy enough for a cold frame in winter, and is of a fine crimson, broadly margined with gold. It is highly effective. Dahlias of different types are not neglected, and there would appear to be a good future before the collarettes for park and public garden purposes.

Many other good features of this, one of the latest additions to the beauty spots of Glasgow, might be mentioned, but enough may have been said to show how well justified is the popularity of the old garden of Ibrox Hill, now open to the public. Mr. James Whitton, V.M.H., the Superintendent of the Glasgow Parks, may well be gratified at the public appreciation of this evidence of his anxiety to improve the public gardens under his care, and Mr. Williamson, the Bellahouston Park foreman, with Mr. Macdonald, who has the immediate charge of the garden, may well be congratulated on their admirable work.

S. Arnott

DAFFODILS IN THE GRASS AT DALHOUSIE CASTLE.

These are growing on the Castle slopes.

AN OLD-ESTABLISHED SUFFOLK NURSERY.

In more than one respect Mr. R. C. Notcutt's nursery at Woodbridge has an individuality quite uncommon among the nurseries of Britain. It has been in existence well over 150 years, and the records of the early days reveal the fact that business was done with county families whose descendants are still numbered among the firm's regular clients. Until less than twenty years ago the name of the owner of this old-established nursery was John Woods, but in the Diamond Jubilee year, after the death of the last male representative of this highly-respected family, the business passed into Mr. Notcutt's hands, who had already established a reputation as a chrysanthemum specialist with a nursery in Ipswich, which, by the way, is still retained, it being here that a varied collection of stove and greenhouse plants is grown.

One scarcely has passed through the entrance gates to the Woodbridge Nursery ere he is confronted with unmistakable evidence of the great age of the garden. For it is more in the nature of a garden than an ordinary nursery—afforded by the remarkably fine magnolias that completely cover the front of the house. There are also in the nursery noble trees of Cedrus Deodora, and a magnificent fern-leaved beech and the maidenhair tree that must have waved their spreading branches in the breeze for many a long year.

At one end of the nursery is a plantation of tall Scots pines, and in a sheltered hollow in this plantation one finds a splendid colony of bamboos growing with a luxuriance that bespeaks entire satisfaction with their environment. Not many nurseries have a collection of bamboos to equal that at Woodbridge, for, in addition to towering masses of Phyllostachys, Bambusa metake, and Arundinaria anceps, there are fine clumps of the handsome foliaged Arundinaria nitida, the neat little B. nana, the graceful Phyllostachys aurea, and P. quadrangularis, with curious four-cornered canes. As a matter of fact, almost all species of bamboos found in this country are seen growing in the Woodbridge Nursery, and Mr. Notcutt is justly proud of his extensive and valuable collection.

That the nursery is more like a garden than an ordinary trade establishment is largely due to the fact that great care is exercised in order that even the stock beds of flowering plants are so arranged that in height, colour, and season of flowering each may contribute its proper share to the harmonious effect of the whole display. The ground rises from the roadside in a gentle slope, so that one obtains a fine view from the offices, and at all periods from spring to autumn a pleasing picture is presented. Hardy perennials are extensively grown, and the collection includes a large number of the best subjects for the border, the rock garden, and for bedding. Romneya Coulteri does wonderfully well here, there being plenty of bushes 5ft. or 6ft. high, and almost as much through. Eremuri were practically past at the time of my visit, but the tall spikes carrying innumerable seed pods bore witness to the glory that had been theirs. Some beds of the newer varieties of Heuchera sanguinea were aglow with crimson and coral-red. The Shirley variety of H. sanguinea grandiflora was exceptionally fine, and it is open to question whether any more dazzling but delightfully elegant plant for a circular bed, or for a group in the herbaceous border is available. Curious, but quaintly beautiful, was Salvia turkestanica hybrida, with large cordate, somewhat hoary foliage, and dense spikes of almost white flowers, arranged in tiers surrounded by mauve-coloured leafy bracts. A colony of this plant grows on the rising margins of a newly-formed water garden wherein aquatic plants have already established themselves

A BEAUTIFUL WATER GARDEN
In the Woodbridge Nursery.

while the boggy stretch of ground surrounding the water has been well planted with spiræas, funkias, irises, and other moisture-loving plants. Astilbe Ceres, A. Davidi, and the increasingly popular pink forms were throwing up a wealth of bloom, and the noble leaves of gunneras, the rising plumes of Arundo conspicua and Gynerium argenteum produced an effect of stately luxuriance.

There is a sunken rockery in the nursery with a lily pool, and shelving rocks adorned with a great variety of alpine plants. Dianthus of sorts, gay helianthemums, and the nodding yellow flowers of Onosma taurica claimed admiration, and although mostly past the flowering stage, one noticed a fine selection of saxifrages, both of the encrusted and mossy sections. Delphiniums receive the attention their striking beauty deserves, and among the many fine-class varieties the one named Mrs. Notcutt particularly pleased me. It produces

dense spike of beautifully symmetrical flowers of pure sky-blue colour.

Away beyond the herbaceous quarters one finds a rich and varied collection of the most useful flowering shrubs, and also of coniferous and other ornamental trees. Hedysarum multijugum was flowering most beautifully, and kalmias, philadelphus, berberis, and cistus were represented by all the best kinds. The collection of cut-leaved acers is very fine, and ornamental vines, wistarias, clematis, and other climbing plants were plentiful.

On a well-furnished pergola the best of the rambler and hybrid Wichuraiana roses run rampant. The white-flowered Una was at the time of my visit just one sheet of glistening whiteness in contrast to the ruddy glow of Paul's Carmine Pillar, and others of varied tints. The bulk of the garden and exhibition roses are grown on the Creek Farm Nursery, which is a recent development due to the growth of the business. Suffice it to say that the collection of roses embraces practically all the varieties worth having. A similar remark may be made in regard to the fruit which is also grown at Creek Farm. The English paradise is the stock most in favour for apples, although certain varieties are also worked on the crab.

A large stretch of land has been permanently planted with fruit trees, there being bush and cordon trees in alternate rows. The latter are entirely unsupported, and are rendering a capital account of themselves, producing fine crops on a quite small space per tree. The plantation includes varieties of the several fruits in cultivation, both dessert and culinary, so that purchasers have an excellent opportunity of comparing style of growth and quality of fruit, as well as cropping capabilities, where all trees are grown under like conditions. Flowering trees, such as cherries, crabs, and the like, are largely grown. A highly ornamental tree that attracted attention was Pyrus malus floribunda purpurea. Its foliage is of a distinct bronzy purple shade, and it bears deep carmine flowers, which are extremely effective.

On still another branch nursery, known as Martlesham Fields, there is a further stock of fruit trees and bushes, and also of forest trees and game covert shrubs, so that altogether Mr. Notcutt's establishment is comprehensive, and embraces practically all branches of the nursery, seed, and florist's business, and it is the more interesting in that while, as here mentioned, there are features that have taken generations to develop, the whole business is to-day carried on in accordance with the modern methods, and among the plants cultivated one finds both the oldest of old favourites and the latest productions of present-day raisers and collectors.

Reference must be made to the Old English Rose Garden, which, surrounded by such a yew hedge as one but rarely sees, is so outstanding a feature of this nursery that it should not be overlooked. This hedge, rising like a solid green wall to a great height, impresses one, perhaps more than anything else, with the great age of this nursery garden, and it forms the most perfect boundary for the rose beds cut in the greensward, with the rough-flagged, straight walks that divide the garden into four quarters, an old, weather-worn sundial standing where the walks cross at right angles in the centre of the garden. In the crevices between the broken flagstones grows the creeping thyme, with stonecrop, thrift, and toadflax for its companions, and in the beds the Provence and the Damask rose, the well-loved moss rose, and the showy Rosa Mundi, seem more at home and befitting than the modern hybrid teas of ever so perfect form. It is no disparagement of the freedom from formality in present-day garden making to admit that in this peaceful little enclosure, where the whole atmosphere seems to belong to long ago, there is a charm and air of restfulness quite distinct from the delights of any other type of garden. VISITOR.

FLORAL TABLE DECORATIONS.

The article on "Table Decoration" in THE GARDENERS' MAGAZINE of August 30 has aroused not only the public interest, but that of the exhibitors themselves. I, as a fairly well known exhibitor, second Mrs. Hales in her remarks concerning rustic stands. These have been most useful, both at the shows and on private dinner-tables, and if anyone should decry them it is surely the florists, simply because the vessels require so few flowers; these can be so lightly arranged, and every bloom can be shown off to perfection.

We do want something new in the table decoration classes to vary the monotony; that is why I like the rustic designs, as one can have high or low decorations. There is not much chance of introducing anything really new at the shows, as most of the judges have a fixed idea, and it is only sheer pluck that allows an exhibitor to venture on a new colour-scheme, much less a new arrangement. There were forty tables at the Royal Botanic Gardens, and a number that secured prizes were very much alike; and if some of the show committees do as Mr. E. Molyneux suggests, viz., limit the height as well, the sameness will be greater than ever. He also seems to think it difficult to hide the silver colour of the rustic stands; that is so in about one instance, where sweet peas with their own foliage is used; otherwise it is really quite simple.

Originality is what we want, and there ought to be a class for it at all shows. There is not a show in town where we can use mixed flowers. I wonder if your corespondent is so restricted. Perhaps he has not thought of that. We have to use flowers according to the show. Most of the classes are open, so why does he not compete? We should all welcome any idea that he has dared to put before his committee.

Now that I am writing on the subject of table decoration, I think there is a great deal to be said about the wording of the schedules, and, to my mind, many alterations are really quite necessary. For instance, lately, at the National Rose Show, one noticed how new blooms and varieties secured first prizes. Ought this to be? When our schedules say, "For the most artistically-arranged dinner-table," what are we to understand by that? Does it mean well-arranged tables shall count, or good blooms? It ought to be made clear, and points given thus: First, artistic arrangement (most essential); second, lightness; third, good style, blending of colours of foliage and flowers; fourth, originality; fifth, quality of bloom.

As there are many like myself who have nearly always to depend on market flowers, this makes it very difficult to compete with more fortunate exhibitors, who are able to grow, or secure, specimen blooms. The principal rose grown for market is Mdme. Abel Chatenay, now quite old-fashioned, but beautiful to decorate with, and a good night colour; but how can it succeed in the eyes of judges who welcome new varieties like Melody, etc., before good arrangement? Table decoration must be considered an art pure and simple, and must not be judged on the quality of the flowers or the new varieties used. At how many private houses can prize blooms be obtained? The thing needed is to arrange, as artistically as possible, nice flowers that can be secured from one's own greenhouse, garden, or shop.

Then, again, there is the size of the table; they may be 8ft. by 3ft. or 5ft. by 3ft. It ought to be stated if the exhibitor is to take those measurements for the centre of a dinner table or that the floral arrangement is to be in proportion with the measurements. One hardly ever sees a 3ft. wide private dinner table. Did your correspondent think what a handicap that is?

I have been most interested in this discussion, and trust it will still continue.

(MRS.) A. ROBINSON.

Norhyrst Park Hill, Carshalton.

DEEP CULTURE AND PRIZE ONIONS

Under the heading, "Some Debatable Topics" in THE GARDENERS' MAGAZINE for October 4, "H." expresses doubt as to the wisdom of deep culture for exhibition onions. That onions are deep-rooting subjects is beyond dispute, and a shallow soil is consequently incapable of producing large, heavy bulbs. I have grown a good many exhibition onions in my time, and call to mind one particular plot on which they were grown for five seasons in succession. In the first place, the plot was trenched and well manured to a depth of fully four feet, the trenching being done six months before the onions were planted. In after years the ground was only dug to a good spade's depth, and there were as many three-pounders in the fifth season as in any of the preceding crops. In my opinion, when once a piece of ground has been thoroughly broken up to a great depth, it is several years before the soil becomes really solidified, and the roots of onions, which, as "H." remarks, like a firm soil, will without difficulty find their way down.

On one occasion, to satisfy my own curiosity, I took out a trench alongside the outer row of the plot, and, with the aid of a small handfork and my fingers, laid bare the roots of the onions, which I found had gone straight down to the full four feet that had originally been dug. To my mind, therefore, although it is quite unnecessary to trench the onion bed every year, it is hopeless to attempt to grow big onions on ground that has not been deeply dug, and well manured right through.

A. J. MACSELF.

ROOT-PRUNING.

Those fruit trees that annually bear but little, if any, fruit, and produce too much soft wood, should have their roots lifted and pruned some time during October and November. Open out a trench quite two feet wide, and fully five feet away from the stem of the tree, remove the soil with care, and thoroughly undermine the roots, severing any that may have grown down into the cold subsoil; trim the damaged ends, and relay all in a fresh, sweet compost. Large trees may have half their roots pruned this autumn, and the remaining half next year. Young trees may have the whole of their roots lifted and relaid at various depths. This is by far the best way to deal with young peach trees until the wood made annually is of medium thickness, and firm, with a brown tinge on the bark; when once the trees begin to make the right class of growth little further attention will be necessary, with the exception of feeding, etc., when the crops are heavy. Old pears and other trees growing on walls and trellises that have become fruitless, but otherwise are healthy, may be greatly improved by carefully removing from amongst their roots all the old, worn-out soil, and giving fresh, sweet turf and bone-meal. All the trees to be lifted should first be thoroughly watered, and before filling up with good soil the drainage should be made efficient. H. MARKHAM.

Saintpaulia ionantha. — The plants raised in spring and fully established in 48's may now be allowed to flower. The best position for them will be a stage or shelf near the glass. Apply a little plant food occasionally, and take care that no fallen flowers remain on the plant to cause damping, a fine show will thus be ensured for the next two or three months. Those raised in May or June should be ready for potting into 48's; keep the plants to a single crown, and remove all flower spikes as they appear. This batch will provide a good display for Christmas and the succeeding two or three months. —H. PRIME.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

CYMBIDIUMS. — The late autumn and winter-flowering cymbidiums, species and hybrids, will now have flower scapes in different stages of development, and should receive every encouragement. Several of these may be successfully cultivated under the same atmospheric conditions as odontoglossums. In fact, we consider C. Tracyanum does far more satisfactorily under these conditions than when grown in a higher temperature; the flowers produced are of finer colour and substance, and are much more durable under the cooler conditions. As most of the cymbidiums do not flower satisfactorily until they have filled their pots with roots, a little weak liquid cow manure may be applied occasionally up to the time that the flowers expand, but manures for orchids must be used with every care and discretion. If there is plenty of root room and a good compost was used when potting, there is little need for any other material, and rain water will generally afford all that is necessary for their successful cultivation. The plants should be placed in a position where they will have the full benefit of available light, as this will prevent the flower scapes becoming unduly drawn and will also assist the development of colour in the flowers when they expand.

POTTING.—Such of the winter-flowering kinds that are producing growths, instead of flowering, may be repotted, and the flowering plants, as they pass out of bloom, should also receive attention. Plenty of good fibrous loam of a lasting nature should be used, with ample broken crocks, charcoal, and sand to render the compost porous.

PERMANENT SHADING should now be removed from the roof glass, and ends of the orchid houses. The ends may have to be covered for a short time during the middle of the day, where they are facing due south, but full advantage should be taken of the available light during the next few weeks, for, after the end of the present month, there is little power in the sun's rays to assist in maturing growth. The roof blinds also must be used with discretion, and should only be lowered where there is a danger of the foliage being injured by the sun. With the cooler conditions prevailing outside, the greater amount of moisture in the atmosphere and the rapid shortening of the days, less damping is needed to provide atmospheric requirements. The temperature of the different divisions should reach the normal degree in the morning before damping is done, and the weather outside will suggest whether further damping will be advisable later in the day.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

EUCHARIS. — Eucharis that have been resting since completing their summer growth will have benefited considerably by the recent spell of lovely autumn weather. Assuming they are now in a slightly heated frame or an intermediate house, to ensure a prolonged supply of their beautiful flowers a few of the most forward plants, which are probably just showing their spikes, should be placed in a temperature of 70 deg. Give them a thorough watering, and maintain genial conditions by occasionally damping between the pots and syringing overhead when the weather is favourable. After the flowering season and just as growth is recommencing a good opportunity is offered for repotting, or for removing some of the spent surface soil, and top-dressing as may be considered desirable. The remaining plants will provide one or two successional batches, and for the present may continue partially resting, though at no time must they be kept excessively dry. Where mealy bug or scale exists, occasional sponging with a strong insecticide will be necessary to keep these pests in check.

APHELANDRA ROEZLI.—This handsome flowering plant will now be showing its spikes, and will require somewhat drier atmospheric conditions. Continue to give occasional applications of weak liquid manure, and of an approved fertiliser, until the colour of the flowers is seen, when only clear water should be given. After flowering a few plants may be retained for the production of seeds, from which stock is easily raised. If large plants are desired, they may be kept somewhat dry, though not dried off, have the flower spikes removed, and when growth recommences in spring they must be shaken out and repotted, with the intention of giving larger pots when ready for them.

ALOCASIAS.—The evergreen species will now require similar treatment to that recommended for anthuriums in a preceding calendar. Deciduous forms should be rested and stored, as recommended for caladiums.

HÆMANTHUS KALBREYERI.—Having completed its growth this should be allowed to rest, and no water will be required until the flower spikes are seen. Evergreen species of Hæmanthus will require less water at the root from now until new growth commences. They require to be wintered in the stove.—H. Prime, Hatfield Gardens.

FRUITS UNDER GLASS.

EARLY PEACHES.—No further time should be lost in having all root-lifting, root-pruning, and any renovating of the borders brought to a conclusion. The summer and autumn have been most favourable to the ripening of the wood, so that any large trees which were prepared last season, by being root-pruned, may now be moved with perfect safety to other positions. The removal of large trees must be carefully and quickly performed; it is also most important that one or two good waterings should be given before lifting is attempted. Peach trees which are kept in good condition lift easily, and soon recover when placed in a fresh position if the soil is well washed in with tepid water, which is the best method of settling the compost amongst the roots. Tie loosely to allow for settling down; keep rather close and syringe frequently, and shade for a few days to prevent distressing the trees more than is necessary. Treated carefully in this way, large trees in full leaf will be re-established in a month or so, and, given ordinary attention afterwards, will be ready for forcing with the other trees.

PRUNING must be very light for lifted trees. Where former directions have been carried out it will be very slight in any case and only the mere removal of a shoot here and there to balance the trees. The same remarks apply to undisturbed trees, except that more of the old bearing wood may be spared, and other shoots which were overlooked at summer pruning. I do not favour the shortening back of bearing wood, but it sometimes becomes a necessity for the proper balance of the trees.

SUCCESSION HOUSES.—Trees in these houses, when well thinned of old bearing wood, and where the buds are well advanced (the best proof of well-ripened wood), should be well watered if this is found necessary until the foliage falls naturally. In many places, there is no help for it, but where possible avoid wintering flowering and other plants in the peach houses, as this keeps the buds in a state of excitement when they should be resting. Such conditions are also favourable to bud dropping, weak flowers, and other causes of failure in the spring.

LATE HOUSES.—Thin out the wood on late trees as soon as possible to let in light and air; a little steady fire-heat can do no harm until the wood is ripe, always providing ventilation is on a liberal scale. Fumigate where there is any suspicion of insects, and frequently wash the trees by means of the hose. Follow on with root-pruning and top-dressing, etc., so that all may be finished off without delay. — F. Jordan, Warter Priory Gardens.

THE FLOWER GARDEN.

SWEET PEAS.—The autumn sowing of sweet peas has greatly increased in favour during the past few years, and the advantages are obvious to all who adopt it. Some growers are very successful with autumn sowing in the open ground early in the present month, but probably the most satisfactory method, especially in localities where the soil lays wet and cold, and where exhibition flowers are required, is to sow the seed in pots. Five-inch pots will be found very suitable for this purpose, and should contain soil to which a good quantity of sand has been added. Seven or eight seeds to each pot will suffice, and these should be covered with about a half-inch of soil. Plunge the pots containing the seeds in ashes, up to the rims, in a cold frame. When the young peas appear, as much air as possible should be given them whenever the weather permits, the lights being left on only during wet and very cold weather; this is a most important detail, and one that has a great effect constitutionally on the plants. Water must be cautiously given, and very little will be required until the days lengthen in the New Year.

SPRING BEDDING.—Much reluctance is often shown in clearing beds of their summer occupants, especially when no early frost has been experienced to make them appear unsightly. To be over-indulgent in this respect is not wise, as the subjects used for spring bedding are much benefited by being planted in good time, so that they may become well rooted before hard frosts set in; and, as bulbs figure largely in such displays, it is necessary to get them planted as early as possible if they are to be satisfactory. After the beds have been cleared, dig in a good dressing of rotten manure.

DAHLIAS.—A few degrees of frost quickly terminates the flowering season of dahlias, and no time should be lost, once that condition is arrived at, in lifting the tubers. As the work proceeds, secure the labels with thin wire to one of the strongest tubers, and afterwards stand the roots in an airy shed to dry previous to storing them away in a cool, dry shed for the winter, where they will be safe from frost and damp, and not subjected to artificial heat, which has a drying effect on the tubers.

TRANSPLANTING TREES AND SHRUBS. — The roots of deciduous trees and shrubs are now less active than at any other period, and, providing the ground is thoroughly moist, it is a most suitable time to commence transplanting them. When moving specimens which have been growing undisturbed for several years, it is most important that the work should be carried out in good time, owing to the fact that many strong roots will be severed in lifting, and the longer these have to develop new root-fibres before the spring growth commences the better. It is not quite such an important matter when dealing with trees and shrubs coming from a nursery, as the practice which most nurserymen follow of frequently moving them prevents the roots becoming coarse, and they are then in a good condition for transplanting. But even in this case early planting is to be recommended.—T. B. Field, Wych Cross Place Gardens.

CLAY'S FERTILIZER THE STANDARD PLANT FOOD

"THERE IS NOTHING LIKE CLAY'S TO BUCK THINGS UP."
The Fruit-Grower.

SOLD EVERYWHERE in 6d. and 1/- TINS; and in BRANDED and SEALED BAGS:—7 lbs., 2/6; 14 lbs., 4/6; 28 lbs., 7/6; 56 lbs., 12/6; 112 lbs., 20/-.
Or direct from the Works, Carriage Paid in the United Kingdom for Cash with Order (except 6d. TINS).

Every Genuine Bag, Tin and Seal bears this Trade Mark.

OF
CHOICE HARDY BULBS.
COLLECTION "F" FOR SPRING GARDENING
Contains **1,140** Bulbs.

48 Hyacinths, distinct colours.	300 Crocus, in 4 distinct colours.
50 Tulips, single early.	100 French Ranunculus.
50 Tulips, double.	50 Snowdrops, single.
50 Tulips, single, late.	100 Spanish Iris.
50 Narcissus, best mixed.	36 Scilla sibirica (2 colours)
30 Narcissus incomparable	4 Lilium umbellatum.
24 Narcissus poeticus.	50 Eranthis hyemalis (Winter Aconite).
24 Anemones, double.	50 Ixias, best mixed.
50 Anemones, single.	24 Triteleia uniflora.
50 Gladiolus nanus.	

HALF OF THE ABOVE FOR **11s.**
Our Bulbs are Perfect Bulbs direct from Holland—THE Great BULB LAND.

The above Package may be had from our Agents,
MERTENS & Co.,
3, Cross Lane, London, E.C.,
On Receipt of Cheque or Post Office Order.

Our **DESCRIPTIVE CATALOGUE** of SPLENDID BULBS (100 pages in English), containing FULL CULTURAL DIRECTIONS, will be sent post free on application to our Agents, as above, or ourselves direct at

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

The Clerk of the Weather has to be primarily thanked for the splendid exhibition held at the Royal Horticultural Hall, Westminster, on Tuesday, October 7. Had he been in a bad temper and given frost and rain a few days previously the show would have been shorn of more than half its glory, because dahlias, and the great majority of the border flowers so finely displayed, would have been a dreary desolation. As though regretting his generosity, the weather man gave us a deluge of rain in the earlier part of the day, but followed this with sunshine and warmth, consequently the attendance at the hall was large. Mr. S. T. Wright informed us that on no previous occasion has there been such a demand for space at the hall.

Besides dahlias and Michaelmas daisies there were many groups of fruit, a good show of autumn-flowering orchids, carnations, late roses, and wonderful exhibits of bamboos and new Chinese trees and shrubs. Novelties were fairly numerous, and of considerable interest.

TREES AND SHRUBS.

Filling a large breadth all along the whole side of the hall was one of the most remarkable collections of new Chinese trees and shrubs ever exhibited. It was from the celebrated gardens at Aldenham House, Elstree, where the Hon. Vicary Gibbs and his able gardener, Mr. Edwin Beckett, V.M.H., do so many wonderful things. This fine collection of trees and shrubs, grown almost entirely in pots, consisted of six hundred species and varieties, many as yet unnamed or determined. Every plant had been raised from seed at Aldenham, and seed sowing commenced in the autumn of 1908. The seeds were collected and sent home by Mr. E. H. Wilson, whose work as a plant collector in China is well known to our readers.

A few of the plants exhibited, like Berberis Wilsonæ, for example, are sure to become popular and general favourites in our gardens, and there are others that will find a place in the larger gardens and pleasure grounds of the country, but there are very many which, as at present known, have little claim to special notice, although of their value as park or woodland trees it is not possible to speak; years must elapse before the full value of Wilson's finds can be estimated. Everyone is grateful, however, to the Hon. Vicary Gibbs for cultivating such an immense collection, and for the opportunity of seeing so many well-grown examples.

In the gold medal group in question a few kinds that seemed to possess merit were the extraordinary broad-leaved willow, Salix magnifica; Ligustrum Pratti, small-leaved, and suggesting a free-growing cotoneaster; Clematis uncinata, with dark purplish-green trifoliate leaves; Liriodendron chinense, a new tulip tree; Ailanthus Vilmorinianus, a very graceful "Tree of Heaven"; Paulownia tomentosa lanata (A.M.), with big palmate leaves; Liquidamber formosana monticola, with dark purple-red leaves; Berberis subcaulialata, of neat and elegant growth; Berberis Sargenti, with large spines and autumn-tinted foliage; and an evergreen perpetual-flowering yellow jasmine. Symphoricarpus mollis, an American plant, crowded with large snow-white berries, also came from Aldenham, and gained, deservedly, a F.C.C.

Dahlias and cut sprays of trees and shrubs from Messrs. J. Cheal and Sons, Crawley, proved interesting; ceanothuses, Genista tinctoria, Amygdalus communis purpurea, Choisya ternata, and Buddleia Veitchianus were notably good things, while Dahlia Crawley Star attracted everyone by means of its bright pink and elegant flowers.

Bamboos were most extensively exhibited by Messrs. James Veitch and Sons, Chelsea; there were about forty species and varieties, and these were represented by large specimens, grouped with grass plumes, along the end of the hall.

HARDY FLOWERS.

Michaelmas daisies were well shown by Messrs. Cutbush and Son, Highgate, and included huge bouquets of the small-flowered Silver Queen, Perfection, Novelty, Ringdove, Ideal, and Simplicity. With these were other varieties, notably Climax, Sirius, and Bluebeard, and small grouplets of perpetual carnations, where the new cerise and heliotrope Mrs. L. Fullerton was conspicuous. Messrs. Barr and Sons, Covent Garden, showed early chrysanthemums in variety, Michaelmas daisies, montbretias, kniphofias in variety, the lovely pink Gladiolus Dawn, and some spikes of the yellow-flowered Groff's hybrids.

Mr. G. W. Chantler, Cockmannings, Kent, filled a table in the fruit annexe with a selection of hardy autumn flowers and dahlias. Messrs. G. and A. Clark, Dover, in their group of hardy flowers, displayed the beautiful Helianthus sparsifolius, the white Delphinium Moerheimi, and the graceful Cimicifuga simplex. Messrs. Gibson and Co., Bedale, put up Verbascum Caledonia in fine form, and a selection of Michaelmas daisies and the light blue form of Lupinus polyphyllus. Mr. A. L. Gwillim, Sidcup, was a small exhibitor of hardy flowers, and showed Campanula Burghalti and the useful Boltonia asteroides, but his chief display consisted of picked blooms of his fine strain of double and single tuberous begonias.

Pot plants of various pretty little polyantha roses were grouped on the floor by Messrs. Paul and Son, Cheshunt; Jessie, Katherine Zeimet, Madame N. Levavasseur, Queen of the Musks, and Mrs. Cutbush were the leading varieties; the same firm contributed sprays of interesting shrubs.

Mr. Ernest Ballard, The Court, Colwall, Hereford, presented new Michaelmas daisies in bulk; Ragtime, loosely single, bluish-lavender; Glory of Colwall, double, pale lavender-blue; Nancy Ballard, and Peggy Ballard, the latter double blue, were a few of the best sorts.

Roses were capitally shown in large stands by Messrs. B. R. Cant and Sons, Colchester; the popular Madame Abel Chatenay, Frau Karl Druschki, George Dickson, La Tosca, Mrs. J. Laing, and Irish Elegance were very much in evidence. Messrs. G. Jackman and Son, Woking, submitted roses in variety, and put up a bank of Climax and other Michaelmas daisies, chrysanthemums, Kniphofia corallina, helianthuses, etc. Mr. G. Reuthe, Keston, including Desfontainea spinosa, Berberidopsis corallina, Schizostylis coccinea, red and white lapagerias, and Gentiana Andrewsi in his group of flowers. Messrs. Price and Fyfe, Grove Park, Lee, were exhibitors of hardy flowers.

The Wargrave Plant Farm, Arcade, Liverpool Street, E.C., put up a big bank of Michaelmas daisies and chrysanthemums, and among the former made special features of Thora, Bianca, Gaiety, Climax, Chastity, Proserpine, Damosel, and other good varieties. Messrs. W. Wells and Co., Merstham, made up a bright autumnal display of chrysanthemums, showing big blooms of Mrs. R. Luxford, Queen Mary, and Mrs. W. Hookey, and stands of smaller blooms of Joan Caster, Monarch, Harrie, Leslie, and the pink Normandie.

Mr. H. J. Jones, Ryecroft, Lewisham, always shows well, and on this occasion used a white paper ground for his sprays of Michaelmas daisies Henry Adams, Climax, Micky Adams (of Climax type), Silver Queen, and Royalty. Mr. Jas. Box, Lindfield, had a splendid bank of autumn flowers, a trifle crowded perhaps, but it contained a fine selection of phloxes and Michaelmas daisies, with the blue Gladiolus Baron Hulot, Lilium tigrinum fl. pl., Cimicifuga simplex, delphiniums, and montbretias. Messrs. Whitelegg and Page, Chislehurst, were large exhibitors of Michaelmas daisies, pentstemons, delphiniums, etc., and had a nice grouping of the pretty Potentilla Miss Willmott, a fine rockwork plant.

A rock garden exhibit from Messrs. Thompson and Charman, Adam Street, Adelphi, contained a selection of encrusted saxifrages, Liatris pycnostachya, the dainty litle daisy-like Lagenophora Forsteri, the equally dainty white-flowered Veronica Lyalli and Primula megasæfolia.

DAHLIAS.

Dahlias were brilliantly exhibited by Messrs. Dobbie and Co., Edinburgh. This firm confined its attention to collarette varieties, and in many instances set up from fifty to a hundred blooms of a variety. Outstanding sorts were Frogmore, Eddystone, Lowestoft, clear yellow; Tuskar, crimson and rose and white; Queen Anne; Clock, lavender; Princess Louise, and the white varieties Inchcolm and Purity. A very fine display for the time of year. Show dahlias were very finely shown by Mr. S. Mortimer, Farnham, the blooms being of large size, full, and richly coloured, especially in the case of the varieties Esmond, Marjorie, Perfection, Wm. Pemberton, and Buttercup.

Mr. J. B. Riding, Chingford, submitted collarette dahlias again, and the attention paid them by the visitors was ample evidence of the way these varieties attract the public. Varieties that met with the approval of the Floral Committee were Carl Bechstadt (A.M.), scarlet, tipped yellow, and yellow disc florets, and General de Sas (A.M.), rich crimson-scarlet with yellow collar and fine stiff stem, very fine. Mr. Riding had also a splendid yellow decorative dahlia named Offenbach (A.M.), of large size, satiny sheen, slightly pointed florets, and splendid stem. These varieties also secured the F.C.C. of the National Dahlia Society. Mr. A. H. Cole, who has now the Swanley Nurseries, put up a considerable variety of dahlias, representing most of the sections.

Pæony-flowered and cactus dahlias associated with Michaelmas daisies, and together, made a pretty exhibit from Messrs. T. S. Ware, Lim., Feltham. The largest display of dahlias was from Messrs. Carter Page and Co., London Wall. This firm staged selections of collarette, pompon, cactus, pæony-flowered, decorative, and single dahlias, and in the midst of these gorgeous autumn flowers they had the fine Cory Cup won at the previous meeting for decorative dahlias.

A particularly pleasing corner group from Messrs. Pipers, Bayswater and Barnes, commanded attention, and was greatly admired. The sides of the corner were filled with towering stands of such handsome pæony-flowered dahlias as Mrs. T. E. Baker, Mrs. W. E. Whinerey, Codsall Gem, The Warrior, Connie Humphreys, Hon. Mrs. Walter Forbes, King Leopold, Mrs. Stanley Hill, and the pink Mrs. R. Copeland. Out in the centre of the corner space, with a path all round it, stood a column of Michaelmas daisies and pæony-flowered dahlias—just that little bit of novelty that proves so interesting and attractive. The firm had also a number of dwarfed Japanese shrubs on view.

GREENHOUSE FLOWERS.

Perpetual carnations were shown by Messrs. Allwood Brothers, who made up bold stands of Fairmount, Mary Allwood, and Enchantress Supreme; with these were some perpetual Malmaison varieties named Majestic, blush; and Exquisite, old rose. A very

bright exhibit of perpetual carnations, set up by Messrs. Stuart Low and Co., Enfield, was very pleasing, and the flowers of St. Nicholas, British Triumph, Snowstorm, Sunstar, and Salmon King were excellent.

Winter-flowering begonias, shown by Messrs. Jas. Veitch and Sons, Chelsea, included splendid varieties we have previously referred to, and there was a newcomer named Optima, the result of crossing B. Pearcei with B. Socotrana; the habit is free and graceful, and the flowers are soft salmon-pink. Celosias in a variety of colours, all carrying fine plumy heads, made up a bright group from Mr. L. R. Russell, Richmond. Messrs. Wm. Cutbush and Son, Highgate, displayed coleus, liliums, the lovely rose-pink Hydrangea General de Vibrage, heaths, etc.

Messrs. J. Hill and Son, Edmonton, presented a grand group of ferns, and put up fine examples of Platycerium angolense, Gleichenia rupestris glaucescens, Davallia repens, Adiantum Farleyense gloriosa, and A. macrophylla. Messrs. H. Cannell and Sons, Eynsford, sent cut pelargoniums in variety.

A small group of new varieties of nerines from Mr. H. J. Elwes, Colesbourne, contained many good things; and Miss Violet Elwes, salmon; Hon. Mrs. H. Beach, rich hued; Salmon Queen, light salmon; Lady Carrington, pale rosy-pink; and Lady Clementina Mitford, a lovely soft pink, were very beautiful. Tricyrtis stolonifera (A.M.) from Mr. Elwes proved very interesting. Messrs. H. B. May and Sons, Edmonton, exhibited well-grown chrysanthemums in pots, exquisite little specimens of Erica mollis, etc., in tiny pots, veronicas, and the newer ferns.

ORCHIDS.

Messrs. Charlesworth and Co., Haywards Heath, put up an effective group of orchids. Oncidium incurvum and odontoglossums lent elegance to the larger deeper flowers and hues of Brasso-cattleya Marie, Miltonia Bleuana nobilior, L.-c. Pallas, Odontioda Brewi callistoglossa, cypripediums in variety, and the lovely autumn-flowering form of Epidendrum vitellinum majus. Mr. E. V. Lowe, Vale Bridge, Haywards Heath, showed a very fine orchid in Cattleya Iris Prince Arthur, with deep maroon petals and sepals. Mr. C. H. Davidson, Twyford, and Mr. H. S. Goodson, Putney, each showed a few orchids.

Brasso-cattleya Iris (C. Iris crossed with Brasso-cattleya Thorntoni) has a fine violet-purple, gold-blotched lip, and mauve-purple sepals and petals; it gained an A.M., and was the feature of a small group of orchids submitted by Messrs. J. and A. McBean, Cooksbridge, Sussex; Cattleya Lord Rothschild albescens was also fine in this group. Mr. C. J. Phillips, Sevenoaks, sent Cattleya Adula Glebe var. (F.C.C.), a beautiful orchid, with old rose petals and buff-rose sepals, and glorious purple lip. P. Ralli, Esq., Ashtead Park, Leatherhead, sent Odontoglossum Crawshayanum superbum (A.M.), carrying white-lipped, yellow, and chocolate-blotched flowers.

Messrs. Armstrong and Brown submitted Cattleya aurea, C. Armstrongæ, Cœlogyne pendurata, Cattleya Fabia, and other good autumn-flowering orchids. Mr. R. G. Thwaites, Streatham, sent forms of Cattleya Iris, and Messrs. Flory and Black, Orchid Nursery, Slough, showed Lælio-cattleya Morna superba, and the pretty Brasso-lælia-cattleya Eric, with a bluish blotch on the fringed lip. Messrs. Hassall and Co., Southgate, had a very bright exhibit, in which the leading subjects were Cattleya Iris, C. aurea, C. Adula, C. Hardyana, C. Hassalli, the chaste C. Harrisoniæ alba, and the handsome Odontoglossum grande.

Fine spikes of Oncidium varicosum were shown by Messrs. Stuart Low and Co., and these arched over blue spikes of Vanda cærulea, Cattleya Harrisoniæ, and Brasso-cattleya Masonæ. Messrs. Sander and Sons, St. Albans, brought up a great variety of orchids, and a few of the more important kinds were Cattleya Mrs. J. W. Whiteley, Lælio-cattleya La Belle, Cypripedium Rich-man, Odontioda Charlesworthi, the curious Eria Mooreana, and the graceful Stelis longifolia.

FRUITS.

A splendid collection of fruit from Mr. E. Neal, gardener to J. A. Nix, Esq., Tilgate, Crawley, proved a great attraction; it consisted of sixty-three varieties of apples grown on the paradise stock, twenty-two varieties of pears grown on the quince stock, and six varieties of grapes all from one house. The finest of the apples were Mère de Ménage, Blenheim Orange, Nancy Jackson, Bramley's Seedling, Peasgood's Nonsuch, Warner's King, Lane's Prince Albert, and American Mother. Of Doyenne Boussoch, Catillac, and Pitmaston Duchess pears there were fine samples. Mr. Neal has proved himself to be a splendid cultivator of hardy fruits, and he deserves full credit for his success in this direction.

Apple trees, lifted from the open and shown in pots, both bush and trained, were very finely shown by Messrs. James Veitch and Sons, Chelsea. Some of the small trees carried over a dozen splendid fruits; Newton Wonder, Lane's Prince Albert, Bismarck, Bramley's Seedling, Landsberger Reinette, and Cox's Pomona were a few varieties that attracted special attention. The new variety, S. T. Wright (A.M.) was very fine; this is a cross between Peasgood's Nonsuch and Bismarck. Mr. P. H. Potter, Pond Farm, Old Malden, submitted two dozen dishes of well-grown and highly-coloured apples, chiefly popular varieties.

The Purfleet School Garden, Purfleet, Essex, exhibited a quite good collection of apples and pears grown in the school garden by lads from eleven to fourteen years of age, on trees planted in November, 1909. There were very fair samples of Golden Spire, Warner's King, Allington Pippin, and Lord Derby. In this garden there are over 150 varieties of fruits, including about thirty varieties of plums. The group included tiny bunches of Esperione grape grown out of doors, on a wooden fence.

CERTIFICATES AND AWARDS.

First Class Certificate.—To Symphoricarpus mollis, from the Hon. Vicary Gibbs (gardener, Mr. E. Beckett, V.M.H.), Aldenham House, Elstree; to Cattleya Adula Glebe var., from C. J. Phillips, Esq., The Glebe, Oak Lane, Sevenoaks; to Apple The Guelph, from Mr. W. Pope, Newbury.

Award of Merit.—To Dahlias General de Sonis, Carl Bechstadt, and Offenbach, from Mr. J. B. Riding, Chingford; to Dahlia The Quaker, from Messrs. Strudwick and Son, St. Leonards; to Helianthus speciosus, from Mr. W. Batchelor, Bruerne Park, Towcester; Paulownia tomentosa lanata, from Hon. Vicary Gibbs, Elstree; to Tricyrtis stolonifera, from H. J. Elwes, Esq., F.R.S., Colesbourne, Gloucester; Nerines Giantess and Gloria of Sarnia, from Messrs. Barr and Sons, Covent Garden; to Nerine Salmon Queen, from H. J. Elwes, Esq.; to Carnation Yellowstone, from Messrs. Allwood Bros., Haywards Heath; to Apple Peacemaker, from Mr. W. Pope, Newbury; to Apple Clivedon Prolific, from Mr. Cam. Cliveden Gardens, Taplow; to Apple S. T. Wright, from Messrs. James Veitch and Sons, Chelsea; to Odontoglossum Crawshayanum superbum, from Pantia Ralli, Esq., Ashtead Park, Leatherhead; to Cattleya Fabia Prince of Wales, from Messrs. Sander and Sons, St. Albans; to Brasso-cattleya Iris, from Messrs. J. and A. McBean, Cooksbridge; to Carnation Queen Alexandra, from Mr. G. Clarke, March.

MEDAL AWARDS.

Gold.—To the Hon. Vicary Gibbs (gardener, Mr. E. Beckett, V.M.H.), Aldenham House, Elstree, for Chinese trees and shrubs.

Silver-gilt Knightian.—To J. A. Nix, Esq. (gardener, Mr. W. Neal), Tilgate, Crawley, for fruit.

Silver-gilt Flora.—To Messrs. Charlesworth and Co., Haywards Heath, for orchids.

Silver Flora.—To Messrs. W. Cutbush and Son, Highgate, for hardy flowers, etc.; to Messrs. Carter Page and Co., London Wall, for dahlias; to Messrs. J. Veitch and Sons, Chelsea, for bamboos, etc.; to Messrs. Armstrong and Brown, Tunbridge Wells, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids.

Silver Knightian.—To Messrs. James Veitch and Sons, Chelsea, for fruit trees in pots.

Silver Banksian.—To Mrs. H. Potter, Old Malden, Surrey, for fruits; to Messrs. B. R. Cant and Sons, Colchester, for roses; to Messrs. J. Cheal and Sons, Crawley, for dahlias, etc.; to Messrs. Dobbie and Co., for dahlias; to Messrs. J. Hill and Sons, Edmonton, for ferns; to Messrs. G. Jackman and Son, Woking, for roses and hardy plants; to Mr. H. J. Jones, Lewisham, for asters and chrysanthemums; to Messrs. Hassall and Co., Southgate, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; to Messrs. H. B. May and Sons, Edmonton, for flowering plants; to Messrs. Pipers, Bayswater and Barnes, for dahlias and Japanese shrubs.

Bronze Knightian.—To Purfleet Council School, Essex, for collection of fruits.

Bronze Flora.—To Mr. S. Mortimer, Farnham, for dahlias; to Messrs. Paul and Son, Cheshunt, for roses, etc.; to Mr. J. B. Riding, Chingford, for dahlias; to Mr. L. R. Russell, Richmond, for celosias; to Wargrave Hardy Plant Farm, Lim., The Arcade, Liverpool Street, E.C., for asters and chrysanthemums; to Messrs. W. Wells and Co., Merstham, for asters and chrysanthemums; to Mr. E. Ballard, Colwall, for Michaelmas daisies; to Mr. J. Box, Haywards Heath, for hardy flowers.

Bronze Banksian.—To Messrs. Thomas S. Ware, Lim., Feltham, for dahlias and asters.

Northern Counties Fruit Congress.

Held at Kendal on September 24 and 25, the Northern Counties Fruit Show and Congress proved a great success. The delegates to the Congress were welcomed and entertained on the evening of September 23, in the Town Hall Assembly Room, by the Mayor and Mayoress, Mr. J. R. Illingworth, and Miss Illingworth. The Rev. J. Bernard Hall suggested that the show and congress should be held at Hexham and Kendal in alternate years. Mr. G. P. Berry pointed out how greatly fruit culture had advanced in the north during recent years, and how the Northern Fruit Congress had encouraged that advance. Mr. Jas. Hudson, V.M.H., referred to the need of increased fruit cultivation and consumption, and to the fact that fruits were often exported from this country.

The opening ceremony on the following day was performed by Lord Henry Cavendish Bentinck, M.P., the Mayor presiding. Mr. J. Hudson, V.M.H., as representing the Royal Horticultural Society, referred to the exhibits, and offered a brief criticism of the show.

He was followed by Mr. Joseph Cheal, who made special reference to the need for greater care in combating insect and fungus pests. Mr. Harper, of Manchester, spoke of the great advantages of proper grading and packing, and said there was nothing better than a 24lb. sieve for uniform packing. Votes of thanks to his Lordship and the Mayor concluded the opening proceedings.

On the Wednesday evening Lord Henry Bentinck, M.P., presided at the Conference, when Mr. C. J. R. Tipper, Director of Education in Westmorland, lectured on "Organisation of the Fruit Industry in Westmorland," and he pressed for the co-operative plan. An excellent discussion followed.

Mr. R. A. Harper Gray, of Armstrong College, then lectured on "Fruit Insect Pests: the Winter and Codlin Moths," and we hope to publish his lecture in a succeeding issue.

The subject for the afternoon meeting on Thursday, September 25, was "Land Tenure and Fruit Culture." Mr. F. W. Crewdson

presided, and the lecture, by Mr. W. F. Emptage, was read by the Rev. J. Bernard Hall. This proved a most interesting subject, and a great point made was that a tenant should have at least a 21 years' lease in front of him when planting fruit on suitable agricultural land. Mr. C. H. Hooper explained the "Evesham Custom" and its advantages, and Mr. G. P. Berry referred to the splendidly-organised raspberry industry in Scotland.

During the afternoon Mr. G. P. Berry, General Inspector of Horticulture under the Board of Agriculture, lectured on "The Culture of Potatoes," and advised prospective planters to have their soil chemically tested, and manured accordingly. Mr. Berry quoted Professor Wallace's formula for manuring for early potatoes: 18 to 20 tons of ordinary farmyard manure, and chemical materials at the following rate—6cwt. sulphate of ammonia, 6cwt. of superphosphate (25 per cent. soluble), 2cwt. of potash salts (35 per cent. solution), 1cwt. guano, containing 6 per cent. ammonia and 40 per cent. of phosphate. This should be applied at the rate of 12cwt. per acre.

At the evening meeting Mr. W. B. Mercer, B.Sc., lectured on "The Diseases of Potatoes." The customary votes of thanks brought the Congress to a close.

Bristol Gardeners' Association.

The monthly meeting of this association was held at St. John's Parish Rooms on Thursday last, Mr. Baston presiding over a large attendance.

The evening was devoted to a lecture and demonstration in table decoration, by Mr. Thoday, who dealt with his subject in a most practical manner, every detail receiving his most careful attention. Numerous questions were asked, and much valuable knowledge gained from the answers. A hearty vote of thanks to Mr. Thoday brought a most instructive evening to a close.

Mr. Coombs was elected assistant secretary, in place of Mr. Wiltshire, who is leaving the district. A hearty vote of thanks was passed to Mr. Wiltshire for his past services.

The prizes for four dishes of ripe fruit were won by Mr. Jennings, first; Mr. Scott, second; Mr. Spry, third. In the point competition Mr. Bird was awarded 93 points for a cypripedium.

TRADE DISCOUNTS.

Did I not read in some newspaper, a few days ago, that a trade society desired to call the attention of the Government (such as it is, worse luck!) to the offer of discounts to gardeners by foreign firms? I rubbed my eyes, adjusted my pince-nez, and read again—Yes, there it was, in cold black and white! The grandest book ever written records an incident in which those who were without sin were invited to cast the first stone! A grand old book, and yet ever new.

F. R. H. S.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of THE GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of THE GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in THE GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

GLASSINESS IN APPLES.—R. L. M., Chepstow: I am sending you a couple of apples which have a very peculiar appearance; they look glassy or waxy. We have many fruits affected in this way, but not to the extent of the examples enclosed. Kindly state whether this peculiarity is caused by a disease; and, if so, what methods can be taken to cure it.—Glassiness in apples is not caused by disease, but is the result, we believe, of moisture getting into the intercellular spaces of the fruits. How the moisture gets there is not well understood, and at present no cure for the trouble can be suggested. Unfortunately, glassiness is more in evidence this year than usual.

THE BEST MICHAELMAS DAISY.—B. R. Y., Lincoln: Following a meeting of gardeners a few days ago, the conversation turned upon Michaelmas daisies, which are exceptionally fine this season, and there was some difference of opinion as to which is the best variety. The varieties that appeared to find most favour were Climax, Ideal, and Beauty of Colwall, curiously enough, all representing distinct sections. As we could not arrive at a definite conclusion, I promised to write to THE GARDENERS' MAGAZINE, and ask you to decide between the three varieties named.—Taste enters so largely into the determination of your question that it is scarcely likely any answer we give will meet with general approval, because "a man convinced against his will is of the same opinion still." Some of our friends are all for the small-flowered and beautifully graceful varieties like Ideal, Chastity, Bianca, etc., while others, still appreciating these smaller-flowered sorts, give preference to the larger flowers of the Nova-belgiæ section. We do not admit that there is any one best Michaelmas daisy, but we are prepared to go so far as to say that, if circumstances compelled us to grow only one variety, and our selection had to be made from the three you name, then we should choose Climax without the slightest hesitation.

DISEASED CHRYSANTHEMUMS.—R. B., Bickley: We hope to reply to your question in our next issue.

STORING CARROTS.—C. G., Portishead: Kindly tell me how best to store carrots. I have an excellent crop, and should like to lift and store them for the winter. As an amateur gardener I take a great interest in THE GARDENERS' MAGAZINE, but have not noticed a reference to this matter, though doubtless most of your readers understand the business quite well.—An open shed, i.e., one with a roof and sides and no front, forming a lean-to against a wall, is a capital place for storing crops of garden roots; but, failing such a shed, the store heap may be arranged at the foot of a wall and shielded from severe cold and wet by means of soil, straw, and a piece of galvanised iron roofing. Lift the carrots carefully, remove the soil from the roots and trim off the tops within an inch or so of the crown. Place a layer of ashes on the ground where the store heap is to be made, and on this lay a little straw or dry bracken. Then add some finely sifted dry soil, and lay the roots, crowns pointing outwards, in a single layer. Add more soil and then another layer of roots, and so on. An endeavour should be made to estimate the amount of space the crop will need, and as the heap is built up it should gradually recede towards the wall, and eventually form the half of a circular-based cone. Until severe weather sets in only a covering of straw or bracken will be needed, with a sheet of iron to throw off the water if the heap is not under cover; but when severe weather is imminent, then the covering of straw or bracken must be thickened and covered with soil, allowing a twist of straw to protrude from the soil and form a sort of ventilator for the heap. This method is subject to several modifications, and most gardeners have their own pet method of dealing with roots, but we have found the method described very successful over a number of years.

NORTH OF ENGLAND HORTICULTURAL SOCIETY: A. L., Manchester.—I think I noticed in your columns lately that the Rev. J. Bernard Hall was retiring from the secretaryship of the North of England Horticultural Society; if that is so, please tell me who is the new secretary.—We believe the new secretary has yet to be elected, but for the present all communications respecting the North of England Horticultural Society should be addressed to Mr. J. C. Jackson, A.C.A., hon. secretary, 26, Bond Street, Leeds.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

H. R. E., Epsom.—1, Berberis Thunbergi; 2, Abutilon megapotamicum; 3, Fuchsia macrostemma.

E. H. O., Limerick.—1, Cornus florida; 2, Eleagnus pungens; 3, Begonia gracilis; 4, Alisma plantago.

S. S., Warwick.—1, Cotoneaster microphylla; 2, Juniperus chinensis; 3, Tsuga canadensis; 4, Verbena venosa.

T. C. J., Southport.—1, Cypripedium Miss; 2, Epipendrum vitellinum majus, autumn-flowering variety; 3, Cattleya labiata.

E. L. P., Iver.—1, Polygonum affine; 2, Cupressus Lawsoniana Allumi; 3, Caryopteris mastacantha; 4, Viburnum Tinus; 5, Penstemon Southgate Gem; 6, Hypericum calycinum.

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor of GARDENERS' MAGAZINE, as advised in the notice at the head of "Answers to Correspondents."

H. W. Durham.—Probably Golden Eagle peach.

D. G., Hereford.—1, a very fine fruit of Gascoyne's Scarlet.

W. C. H., West Bromwich.—1, Adam's Pearmain; 2, Court Pendu Plat.

P. R., Merton.—1, Cox's Orange Pippin; 2, Fearn's Pippin; 3, Wealthy.

R. R., Warminster.—1, Mother Apple; 2, Dutch Mignonne; 3, Ecklinville Seedling; 4, Golden Noble.

J. B. C., Exmouth.—1, Fearn's Pippin; 2, Mabbott's Pearmain; 3, Warner's King; 4, Buerre d'Amanlis.

A. E., Wolverton.—1, Colonel Vaughan; 2, not recognised; 3, Tyler's Kernel; 4, Brownlee's Seedling; 5, King of the Pippins; 6, Bismarck.

S. T. H., Hungerford.—1, D'Arcy Spice; 2, Lemon Pippin; 3, not recognised; 4, probably Chelmsford Wonder; 5, Cornish Aromatic; 6, Blenheim Pippin.

VOL. LVI.—No. 3,129. SATURDAY, OCTOBER 18, 1913.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Tulips.

Tulips, which are now so highly appreciated for the aid they are so well able to render in beautifying the flower garden during the spring months, have had a somewhat chequered career during the three and a half centuries that have elapsed since Richard Hakluyt, writing in 1582, recorded the fact that "within these four years there have been brought into England from Vienna, in Austria, divers kinds of flowers, called tulipas." They were at once regarded with great favour, and their increase by means of seeds was entered into with much spirit; and Gerard has an interesting note relating thereto in his "Herball," which was published in 1597. He writes: "My loving friend Master James Garret, a curious searcher of simples, and learned apothecary in London, hath undertaken to find out, if it were possible, the infinite sorts by diligent sowing of their seeds, and by planting those of their own propagation, and by others received from his friends beyond the seas, for the space of twenty years not being able to attain to the end of his travail, for that each new year bringeth forth new plants of sundry colours not before seen; all which to describe particularly, were to roll sisiphus stone or number the sands." The work so well begun by Garret was taken up by others, and, as the result of their labours, an immense number of beautiful varieties, evincing a wide diversity of form, were raised and introduced to cultivation. For a long time tulips enjoyed a high degree of popularity, and about the middle of the seventeenth century such high prices were paid for the bulbs of the leading varieties in Holland and France as to bring ruin to many. Tulips were held in high estimation by the British florists until the nineteenth century was well advanced, and societies devoted to them were a hundred years ago, if not as plentiful as blackberries at Michaelmas, very numerous in and around London and other great centres. Towards the middle of the century there was a decrease of interest in the delightfully-marked show flowers and the collections slowly disappeared. This was not all that befell the tulip. The use of tender plants for the production of summer effects was introduced, and the fashion became so general that, as in the case of many other hardy plants of great beauty, the decorative varieties, now known as cottage tulips, were banished from gardens of any pretensions. Happily, the majority of the finest of them obtained refuge in the gardens of cottagers and others, who cared but little for blue lobelias, yellow calceolarias, and scarlet pelargoniums, or were unable to incur the expense involved in the annual renewal of stocks of them. Now the garden tulips have returned to their own, and, as we enjoy the surpassing beauty of a tastefully-arranged selection during the season of flowering, it is impossible to suppress a feeling akin to wonder that fashion should have been so blindly followed as to prevent for a long period owners of gardens enjoying the varied charms of the cottage or May-flowering tulips. The show varieties, on which the older florists lavished so much love and care, have not been able to regain their popularity, and afford opportunities for becoming acquainted with their distinctive characteristics. As a counter-balance owners of gardens are able to plant, grow, and enjoy the beauty of the Darwins and Rembrandts, which have been been developed by means of cross-fertilisation and selective culture within quite modern times. Those who give their attention to garden tulips have their preferences, not only for different varieties, but for the sections, and sometimes this preference is shown by a disparagement of others. To refer otherwise than appreciatively to either section is a mistake, for, while one section may appeal the more strongly to some tastes than others, it should be recognised that all possess much value in garden decoration, and can be utilised to advantage. To produce a continuous display of the flowers of these bulbs over the longest possible period, and less should not satisfy the owner of a garden of some size, all the important sections must be pressed into service. A free use must be made of the Dutch varieties which bloom in April, when bright colouring is especially appreciated, and if they do not possess the grace of the chief sections that bloom a month or so later, they have finely-formed flowers, so varied in colouring as to admit of the production of colour schemes suited to the most varied tastes. The reader has only to refer to a fairly comprehensive bulb catalogue to find how wide is the range for selection, even among the cheapest varieties. If Coleur Cardinal and Crimson King are selected from the crimson-scarlet varieties, Dusart, Maas, and Vermilion Brilliant from the bright scarlets, Duchess de Parma and Keizerkroon from those with flowers coloured scarlet and gold; Prince of Austria and Thomas Moore from those having orange-red flowers. Ophir d'Or and Yellow Prince from the yellows, Cottage Maid, Fabiola, President Lincoln, Proserpine, and Rose Grisdelin from the pink and rose shades; and La Reine and White Potterbakker from the whites, a selection will be obtained that will enable the owner to produce colour schemes of great beauty. The Darwins and Cottage tulips bloom at much the same time, and three or four weeks later than the Dutch varieties, and are especially suited to border cultivation. They produce fine effects in the beds, but when arranged in groups in mixed borders, there is not the same

MR. G. E. GREENHOW.

necessity for disbudding the bulbs before they have completed their growth, as in the case of flower beds that have to be cleared for the purpose of preparing them for their summer occupants. We need not give the names of varieties in these two sections, because their merit is high throughout, and there will be little risk of obtaining flowers of decided inferiority, even if the selection is limited to those of quite moderate price. The use of the Darwin and Cottage tulips should not be limited to filling beds and borders in the flower garden, but be planted in the reserve ground or kitchen garden for the supply of flowers for indoor decorations. Flowers of tulips stand remarkably well when in water, provided they are cut before they reach an advanced stage of development, and the end of their stalks placed in water immediately on their severance from the plant. To those who fully appreciate the distinctive beauty of the Darwin and Cottage tulips, a fairly comprehensive selection will afford immense pleasure and unbounded interest throughout the season of flowering. From six to twelve bulbs of each variety will suffice, and these should be planted in a border convenient of access, and where they can remain undisturbed until the leaves reach a stage that clearly indicates the completion of their functions. With these should be included some of the finer of the specific forms which are now sufficiently numerous to form a considerable collection and to afford much pleasure.

Mr. George E. Greenhow, the newly-appointed lecturer in horticulture to the Aberdeen and North of Scotland College of Agriculture, was born at Hulton-in-the-Forest, where his father is still head gardener to the Dowager Lady Vane. Under his father's care, Mr. G. E. Greenhow served an early apprenticeship, and so was well trained ere he passed on to Greystoke Castle, and subsequently, with added experience, to Styford Hall. From Styford Hall, after a term of three years' service, he became gardener to the Northumberland County Council, at Cockle Park, Morpeth, where the horticultural and forestry departments came under his charge. Seeking to widen his experience, Mr. Greenhow went to the Royal Botanic Garden, Edinburgh, and after two years and a-half very profitably spent at that famous establishment, he passed on to become assistant lecturer in horticulture at the East of Scotland College of Agriculture. Later on the Fife and Kinross area of the college activities came under his direct care and supervision, and it is from that responsible post he has been appointed lecturer at Aberdeen. Mr. Greenhow has taken advantage of every opportunity for increasing his knowledge of horticulture and its allied arts and sciences, and rarely has a man been so well equipped for the duties he now takes up.

Anglo-American Exposition at Shepherd's Bush.—Arrangements are being made for holding an exposition at Shepherd's Bush from May to October next year in celebration of the centenary of Anglo-American peace, and on Tuesday afternoon a meeting of the general committee was held at the Mansion House under the presidency of the Lord Mayor. Reports on the progress that has already been made were read by the Earl of Kintore, chairman of the executive committee, and by the chairmen of several of the sectional committees. Horticulture will, we understand, receive due prominence in the scheme. Among the horticulturists present we noticed Sir Jeremiah Colman, Bart., V.M.H., Mr. John Green, and Mr. George Gordon, V.M.H. A special committee has been formed for horticulture, arboriculture, and forestry, and the members thereof are Mr. Edwin Beckett, V.M.H., Mr. Fred. J. Chittenden, F.L.S., Mr. Oswald B. Cowley, Mr. Edward Davidson, Mr. George Gordon, V.M.H., Mr. John Green, Professor F. Keeble, F.R.S., Mr. George Marshall, Mr. Arthur W. Paul, F.L.S., Mr. Spencer Pickering, F.R.S., Dr. A. B. Rendle, F.R.S., Mr. Donald McDonald, F.L.S., Major A. L. Renton, Mr. Martin J. Sutton, Mr. Fred. V. Theobald, F.E.S., Sir Everard im Thurn, K.C.M.G., Hon. J. H. Turner, and Mr. R. W. Wallace.

"Gardeners' Magazine" Rose Number.—The season of rose planting on which we have just entered has, in consequence of the remarkable increase in the popularity of roses, the promise of proving one of the busiest on record. The remarkable extension of rose culture has given rise to a largely increased desire for information on the selection of varieties and the various cultural details requiring attention at this season of the year, and for the purpose of assisting our readers we shall devote our next issue (October 25) chiefly to roses. The subjects that will receive prominent attention will be "The New Roses of the Year," "Roses for Arches," "Roses for Beds and Borders," "Pot Culture of Roses under Glass," "Roses for Pillars," "The New Hybrid Briar Race," and "The Best Roses for Standards." The issue will be freely illustrated, and the illustrations will include several of the new roses introduced during the current year.

Rose Wedding at Worksop.—Mr. Henry Vessey Machin, of Gateford Hill, Worksop, one of our foremost amateur rosarians, was married on October 2 to Miss Evelyn Mary Hawson. The wedding ceremony was largely attended, as both bride and bridegroom are very popular in Worksop. From a horticultural point of view, the ceremony was remarkable for the profusion with which roses were used in all the decorations; every pillar and every window of St. John's Church was wreathed with roses, and there were splendid blooms over the reredos and in the candelabra. The flowers used came chiefly from Mr. Machin's garden, but Messrs. Alex. Dickson and Sons, of Newtownards, sent over a thousand blooms, and also arranged the Mdme. Abel Chatenay roses on the shepherds' crooks carried by the bridesmaids. The bride's dress had roses for its design, and the bride's bouquet consisted of Molly Sharman Crawford roses. All rosarians join with us in wishing that every happiness may attend the Squire of Gateford Hill and Mrs. H. Vessey Machin. Mr. Machin is a vice-president of the National Rose Society, an ardent horticulturist, a keen huntsman, and a successful breeder of cattle.

Ghent Autumn Show.—The last of the flower shows to be held in connection with the Ghent International Exhibition will take place on October 25 to 28. The schedule provides for 256 classes for chrysanthemums, other flowers, fruit, vegetables, etc. A supplementary schedule, adding further chrysanthemum classes, has recently been issued. The premier prize is a work of art, value 1,000 francs, for the finest group of chrysanthemums, not less than 250 plants. The second prize in the same class is a gold medal, value 500 francs. About 40 classes are devoted to chrysanthemums in all. The others are for ornamental-flowering plants, floral art, hardy plants, hardy shrubs, orchids, apples, pears, stone fruit, grapes, market garden produce, in various sections. Coincident with the show will be held the annual congress of the French Chrysanthemum Society. Various questions relating to the flower will be considered, and a programme of festivities issued. We note that on Saturday, 25th inst., the jury and Floral Committee will meet, the opening of the show will take place, and a visit will be paid to the International Exhibition. On Sunday, October 26, visits to the great nurseries will be made, and a reception of the members of the Congress by the Royal Agricultural and Botanical Society of Ghent. On Monday, October 27, there will be a morning and an afternoon session of the congress. Official banquet in the evening. Tuesday, October 28, an excursion toBruges; visit to Sander's Nursery. Lunch given by M. Firmin de Smet.

Grass Lawns at Ghent.—The beautiful grass lawns have been one of the most attractive features of the great international exhibition now being held at Ghent. It is therefore a matter of some interest to learn that the success has, in a large degree, been achieved by sowing Messrs. Sutton and Sons' grass seeds, for which the Reading firm has been awarded a Grand Prix by the jury.

Accident to Mr. H. C. Prinsep.—Our old friend, formerly of Buxted Park Gardens, and now residing at Brookthorpe, Gloucester, was travelling home the other evening after a visit to the famous Toddington Orchards, where he met Mr. G. P. Berry, the Inspector of Horticulture, when a motor car ran into his conveyance and smashed it. By great good fortune Mr. Prinsep was uninjured, and we congratulate him upon his providential escape.

Presentation of Fruit to the Lord Mayor.—In accordance with an ancient custom, the Worshipful Company of Fruiterers made, a few evenings since, the annual presentation of fruit to the Lord Mayor of London. In making the presentation the Master of the Company (Mr. J. C. Hewlett) said that, as usual, the whole of the fruit had been grown in the British Isles, and admirably illustrated the high position to which fruit culture had attained therein, and helped to bring before the citizens an industry of much importance. The Lord Mayor, in acknowledging the gift, said he accepted the magnificent collection of fruit with great pleasure, especially as it must bring home to every one who had an opportunity of seeing it the great potentialities of the great industry with which the Fruiterers' Company had been so long associated.

Trials at the Wisley Gardens in 1914-1915.—The following trials will be held in the Wisley Gardens of the Royal Horticultural Society during 1914-15: Melons, of which ten seeds of each variety are to be sent in February. Tulips, of all descriptions, as mentioned in another paragraph. Herbaceous phloxes, three plants of each to be sent in February. Early flowering outdoor chrysanthemums, three plants of each to be sent in March. Perennial stemons, three plants of each to be sent in March. Perennial sunflowers (including heleniums and rudbeckias), three plants of each to be sent in February. Asters, French, German, or China, seed to be sown in February. Broccoli, one packet of seed of each to be sent in February. French beans, outdoor, one pint of seed of each to be sent in March.

Proposed Trials of Tulips at Wisley. — The Royal Horticultural Society has been asked to take the lead in drawing up a list of correct names of tulips. This the Council will gladly do, provided the Dutch bulb growers will cordially co-operate. The proposal is to plant the autumn at Wisley (where tulips do well as

representative a collection of all descriptions of tulips as can be got together, and then, when they are in bloom, it is hoped the Dutch bulb growers will send over some of their best men to co-operate with the Council in determining the correct names. All who can assist are invited to send, as soon as possible, five bulbs (named) of each variety, to the Superintendent, R.H.S. Gardens, Wisley, Ripley, Surrey, England.

Perpetual-flowering Carnation Society.—Having concluded arrangements with the Bournemouth authorities, this society will hold its second provincial show in the Winter Gardens of this popular resort on April 29 and 30, 1914. The famous musical conductor, Mr. Dan Godfrey, has charge of the local arrangements, so that a highly successful exhibition is anticipated. The society's annual winter show will be held at the R.H.S. Hall on December 3. New members joining before October 31 will receive the 1913 "Year Book," and all other privileges until October 31, 1914. Schedules may be had on application to Mr. T. A. Weston, hon. secretary, Orpington.

Distribution of Surplus Bedding Plants in London.—The surplus bedding plants in the London County Council parks and gardens will be distributed to the public to-day (Saturday, October 18). Persons desiring to participate in the distribution should make personal application at the parks or gardens. The distribution will commence at 9 a.m., and terminate not later than 11 a.m. Plants will not be handed to children under the age of 14, unless they present a note from their parents or teachers.

Nerine Bowdeni Out of Doors.—Some raisers who are especially interested in bulbous plants are aiming at a race of variously coloured hardy nerines—at least, hardy in favoured situations. With this end in view they are using Nerine Bowdeni as a parent, because this is about the hardiest kind we have. At Kew, in a warm border in front of the orchid houses, where gerberas are now flowering, and where Amaryllis belladonna is a fine sight in its season, Nerine Bowdeni has been planted, and at present there are about a score of spikes or umbels of its rosy flowers. At the recent R.H.S. meeting a very strong-growing hybrid named N. The Giantess gave evidence of extreme vigour and freedom, and suggested further possibilities, when others, like it, have been raised from N. Bowdeni.

United Horticultural Benefit and Provident Society.—For the purpose of advertising its usefulness the above society, through its committee, has just issued a large, stout card, 19 inches by 12½ inches, on which are printed in bold characters the chief aims and objects of the society, together with amounts of subscriptions and benefits. We notice with pleasure that the society has £42,000 invested. The card referred to—which, by the way, has calendars for 1914 and 1915 attached, so is well abreast of the times—has been distributed among leading gardeners and nurserymen, and a covering letter has been sent by the secretary, Mr. A. C. Hill, Alexandra Road, West Kensington Park, asking the recipients to place the card in a prominent position in one or other of the dwelling-places or offices in the garden or nursery. The committee ask those who have it in their power to do so to use their influence in attaining the objects in view, "believing that by placing the advantages of membership of this society before journeymen and apprentices in gardens, they are serving, not only the best interests of the society, but of the young professional gardeners also."

CATTLEYA ADULA THE GLEBE VARIETY.

A beautiful hybrid orchid, with bright old rose petals, and buff-rose sepals, and a handsome violet-purple apex to the broad lip. F.C.C., R.H.S., October 7. C. J. Phillips, Esq., The Glebe, Oak Lane, Sevenoaks.

Burnham Beeches. The members of the Coal and Corn and Finance Committee of the City of London recently paid their autumn visit to Burnham Beeches, under the direction of the chairman, Mr. Deputy Morton, M.P. The beeches were found to be wonderfully green for the time of the year, a few frosts being needed to turn this delightful tract of country into a fairy land of russet and gold. A halt was called at a point on the north-west side of the Beeches, and there the Chairman planted a fine young beech, close to the entrance to an unnamed road—leading from the main highway to Halse Drive—which was afterwards christened "Morton Drive."

Southampton Chrysanthemum Show, originally fixed for November 4 and 5, will be held on Tuesday and Wednesday, October 28 and 29, in the Coliseum, Portland Terrace, Southampton.

JULY-FLOWERING LILIUMS.

While it is impossible to define the actual flowering period of lilies, so much depending on the season and the situation of the garden, the species and varieties named below may be expected to be at their best during the month of July. A few of them may commence to blossom during June; while others, like the Panther Lily, which lasts in good condition for some time, may continue well into the month of August.

Lilium giganteum.

Groups of this lily in the flower garden and pleasure grounds are few and far between, the reason for this generally being lack of knowledge of its cultivation. Most lily bulbs, whatever their size, push up flowering stems the first season after planting, but, unless the bulb is a large one, the Giant Himalayan Lily does not do this, but builds up a good bulb, perhaps taking two or even three years before producing a vigorous flower-stem 5ft. to 10ft., sometimes even more, in height. Another peculiarity is that after flowering and producing seed the bulb dies; but it also generally leaves several offsets in the ground, which in their turn, on reaching maturity, produce flowering stems. A stem may carry from six to eighteen, possibly more, of the long tubular, white blossoms, which are streaked inside with purple. The large heart-shaped leaves are also a distinct and attractive feature of this lily. L. giganteum is one of the most proliferous lilies in seed production, and it is also one of the longest in reaching the flowering stage after sowing the seed. Yet the noble flower-spikes are worth waiting several years for, and, when once a commencement has been made, a few seeds sown each year as soon as ripe will ensure an annual production of flowering stems; while, when planted in favourable surroundings, the bulbs also develop offsets. Choose half-shaded positions for planting, where the subsoil is moist, and do not cover the bulbs with more than about two inches of soil.

L. longiflorum.

It would probably not be an exaggeration to state that there are as many, if not more, bulbs of the White Trumpet Lily sold annually in this country as of all the other lilies put together. Market growers purchase the bulbs by the thousand and grow them under glass to supply the demand for cut flowers; and in public and private gardens hundreds are used, both under glass and outside, for decorative purposes. Whether it is because the bulbs can be purchased at such a small cost that it would not pay to cultivate the bulbs in this country, or may be the climate and soil are not favourable for the free growth of the bulbs, the fact remains that the imported bulbs fail to establish themselves in our gardens, and it is necessary to frequently replenish the stock. It is not a difficult matter to raise the bulbs from seeds, but as a commercial venture the competition of imported bulbs is apparently too great for such an undertaking to be successful. Japan, and in a lesser degree Holland and South Africa, supply the imported bulbs. Though thousands of acres of the White Trumpet Lily are cultivated in Japan, experts who have studied the subject are inclined to the belief that L. longiflorum is a native of China.

A gross-feeding, stem-rooting lily, the bulbs should be planted 8in. or 9in. deep in light, well-drained soil, containing plenty of grit and leaf-mould or peat. In addition to the type there are several improved varieties or forms. Harrisi and formosum are early-flowering varieties recommended for pot culture; eximium, or Wilsoni, is a very free-flowering dwarf variety; giganteum, or robustum, is a vigorous form, and perhaps the most desirable for outdoor planting; and Takesima, which has dark stems, and the outside of the trumpet tinged with brown.

L. japonicum.

This species, more often grown in gardens as L. Krameri, is a lily which every enthusiast tries to grow, but few succeed in permanently establishing the bulbs in their gardens. It is an easy matter to purchase imported bulbs of this lily annually coming from Japan, but these seldom flower more than once or twice, failing to become established. L. japonicum is worth much trouble in its culture, and success seems most likely by raising seedlings. The flowers are funnel-shaped, pink or blush in colour, borne on a slender stem 2ft. to 3ft. high; usually one to three flowers, occasionally more, on a stem. Plant the bulbs among low-growing shrubs in a mixture of sandy loam, leaf-mould, and peat.

L. japonicum var. colchesterense—also known as L. Browni var. odorum—is not unlike L. Browni in general appearance, but the leaves are shorter and broader, while the interior of the flower is not so dead white, and the outside is not so dark. The flowers are deliciously fragrant, and the plant, on the whole, is a better grower than L. Browni. A stem-rooting lily, plant the bulbs 5in. to 6in. deep in light, well-drained soil. The average height of the stems is from 2ft. to 30in.

L. Humboldti.

A Californian lily, growing to a height of from 4ft. to 5ft.; resembles in some respects the well-known L. pardalinum. When established, a single stem may bear twelve to twenty recurved orange-red flowers, splashed with purple. The variety magnificum is an improvement on the type. This lily will grow in a well-drained light loam, and should be planted 7in. to 9in. deep.

L. Thayeræ.

This is a Chinese lily, introduced by Mr. E. H. Wilson when collecting during his second journey for Messrs. Veitch, of Chelsea, in 1904. For some time this lily has been grown in gardens as L. sutchuenense, a species, also from China, introduced by Father Farges, a French missionary. Under cultivation the lily introduced by Mr. Wilson proves to be quite distinct from L. sutchuenense, and for garden decoration is far more valuable. Growing 3ft. to 4ft. high, occasionally more, the stems of L. Thayeræ are thickly clothed with lance-shaped leaves, and carrying up to twenty-five flowers and buds. With its orange-red flowers, much recurved, and black spots, this lily might be described as an early-flowering tiger lily, though it lacks the familiar bulbils in the axils of the leaves of that species. L. Thayeræ is an easy lily to raise from seeds, flowering in two or three years from the time of sowing. A stem-rooting species, the bulbs should be planted from 6in. to 8in. deep. It thrives well in ordinary garden soil, and is also adapted for cultivation in pots.

L. carolinianum.

This is a rare lily, in the way of L. superbum, but is not nearly so free in flowering, and not often seen. The dainty, reflexed, orange-red flowers, spotted with maroon, are borne on stems 2ft. to 3ft. in height, and are pleasantly fragrant. A native of the Southern United States, this is another lily to plant 4in. to 5in. deep among shrubs of the erica family.

L. Browni.

This is a very old inhabitant of our gardens, coming, presumably, originally from China, as Mr. Augustine Henry collected wild specimens in that country some twenty-five years ago. Annual importations reach this country from Japan and Holland, but comparatively few of these bulbs establish themselves in our gardens. Growing about 2ft. in height, the large trumpet-shaped flowers are white inside, with conspicuous brown anthers, the exterior chocolate-brown. One to three blooms are produced on a stem. L. Browni appears to thrive best in a light, sandy soil, in which flaky leaf-mould and peat have been liberally incorporated. A stem-rooting lily, plant the bulbs 6 to 8in. deep.

A. OSBORN.

(To be continued.)

SUGGESTIONS FOR BORDER PLANTING.

A delightful feature in many gardens is to combine beauty with utility, and nowhere is the charm of flowers more acceptable than when plants are skilfully introduced as a screen or foil to the various occupants of the kitchen or fruit garden. The latter in themselves present no indifferent picture when wreathed with their beautiful flowers in spring, and again in autumn, when the fruits take on their ruddy tints, so that a combination of flowers at these seasons adds considerably to the attraction of the garden. A simple and effective display is produced here by Aubrietia deltoidea, planted as narrow borders at the foot of cordon apple trees; the mauve of the aubrietia is charming in contrast with the rose, pink, and white of the apple blossom, and the display is by no means a short one. Three double borders were planted respectively with German iris, antirrhinums in various colours, and different kinds of annuals. Fruit trees occupy the borders, and are planted at regular intervals, so that they appear let in a carpet of flowers, and rivet attention, and the ordinary occupants of the kitchen garden have their presence scarcely revealed.

One of the most satisfactory borders of the past season consisted of a broad belt of mixed Sweet Williams arranged in front of apple trees, with a single row of Viscaria oculata cærulea as an edging. The growth of this free-branching annual interlaced among the Sweet Williams, and the rich green foliage of the apple trees, formed an ideal background for the flowers.

Recently I visited some Scottish gardens, where a similar idea is carried out, in one case with pentstemons planted in bold groups of a kind; in another instance East Lothian stocks were used in distinct colours, and a third had China asters, while several examples had antirrhinums, both tall and intermediate varieties being used, a sure index of the great popularity these handsome and easily-grown subjects enjoy.

THOS. SMITH.

Coombe Court Gardens.

NEW PLANTS, FLOWERS AND FRUIT.

NERINES.

The Giantess.—A large-flowered nerine, with elongated blooms borne in a large and slightly lax umbel. The colour is a bright shade of rose. We understand this is the result of crossing N. Bowdeni with N. corusca major. A.M., R.H.S. Messrs. Barr and Sons, Covent Garden, W.C.

Glory of Sarnia.—Evidently a Guernsey-raised variety, derived from N. Fothergilli major crossed with N. corusca major. The flowers are of good size, and carried in a shapely umbel. The colour is brilliant scarlet of a peculiarly "live" shade. A.M., R.H.S., October 7. Messrs. Barr and Sons.

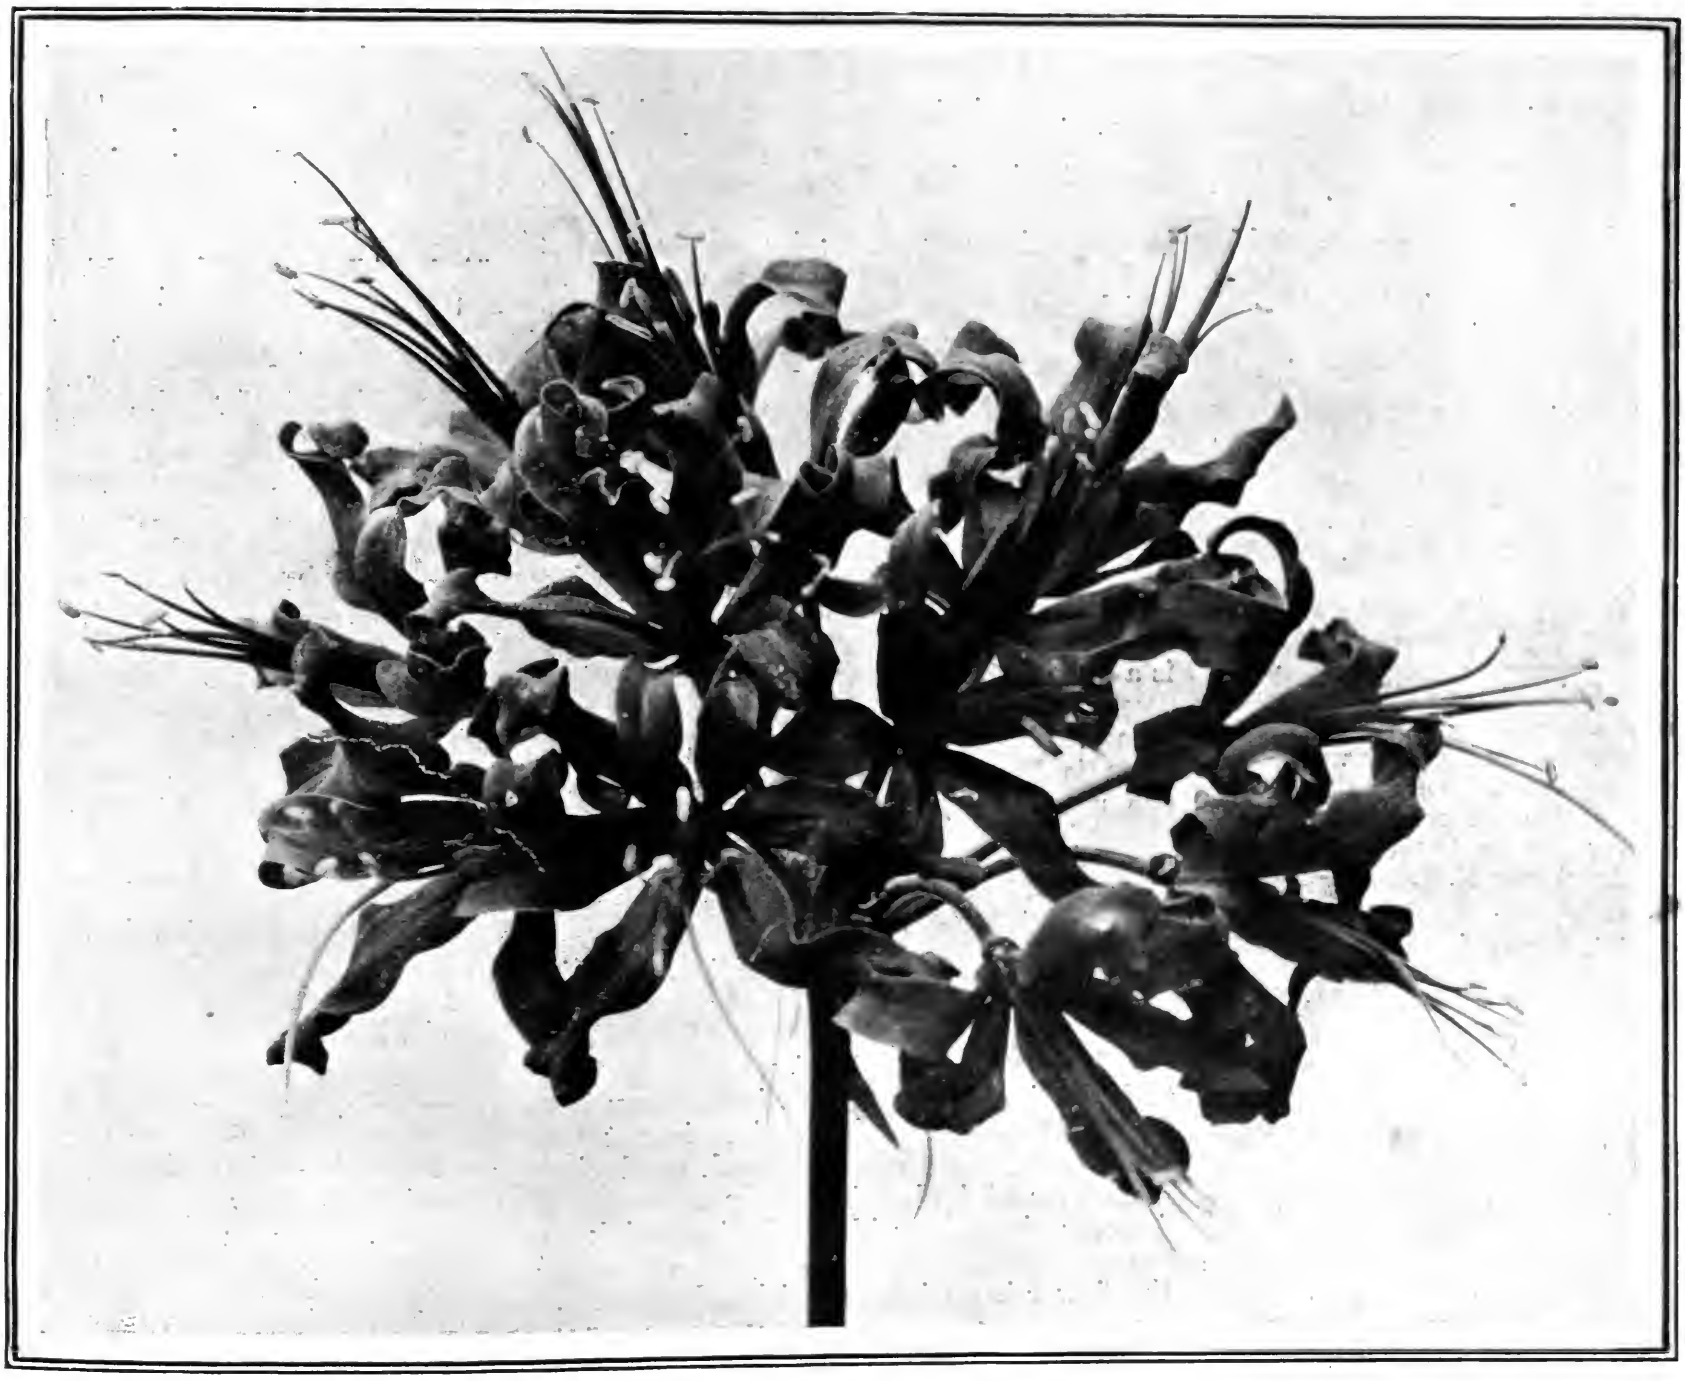
Salmon Queen. — A very beautiful nerine which carries a compact umbel or truss of finely-formed salmon-pink flowers. The segments reflex regularly, and the whole of the inflorescence shows how far florists have advanced in the improvement of these beautiful bulbous plants. A.M., R.H.S., October 7. H. J. Elwes, Esq.

CATTLEYA ADULA GLEBE VAR.

This is a very fine form of the increasingly popular hybrid derived from C. bicolor and C. Hardyana; indeed, The Glebe variety is by far the finest that has yet come before the public. The flowers are very shapely, the petals a lovely rich old rose shade, and the sepals old rose with a buff suffusion. The fine lip is remarkable for its spreading, violet-purple apex. F.C.C., R.H.S., October 7. Mr. C. J. Phillips, The Glebe, Oak Lane, Sevenoaks.

CATTLEYA FABIA PRINCE OF WALES.

A remarkably large and richly-coloured form of the fine autumn-flowering C. Fabia, which is the result of crossing C. aurea with C. labiata. The variety under notice has larger flowers than usual, and the colouring is rich deep purple, the lip royal purple with golden lines in the throat. A.M., R.H.S., October 7. Messrs. Sander and Sons, St. Albans.



NERINE GLORY OF SARNIA.

Flowers of a rich glowing scarlet colour, borne in a large and shapely cluster. A.M., R.H.S., October 7. Messrs. Barr and Sons, Covent Garden, W.C.

BRASSO-CATTLEYA IRIS.

A handsome hybrid with large and beautiful flowers, the sepals and petals soft rose-purple, and the large fringed lip deep purple with a dull yellow throat. A.M., R.H.S., October 7. Messrs. J. and A. McBean, Cooksbridge.

ODONTOGLOSSUM CRAWSHAYANUM SUPERBUM.

A distinct advance on the original hybrid, and the well-grown plant displayed bore a tall spike of large and handsome flowers. The yellow ground colour served to show up the purple-brown markings, and the large white apex to the lip, with purple spots and golden disk, added to the other attractions. A.M., R.H.S., October 7. Pantia Ralli, Esq., Ashtead Park, Leatherhead.

TRICYRTIS STOLONIFERA.

The genus tricyrtis is a small one, consisting of plants with creeping root-stocks, erect slender growths, and lily-like leaves. T. stolonifera has flowers a couple of inches across with prominent stamens. The colour is rose-purple, with brownish spots. A very interesting liliaceous plant. Of doubtful hardiness, found in Formosa by Mr. Price when visiting the island with Mr. Elwes. A.M., R.H.S., October 7. H. J. Elwes, Esq., F.R.S. (gardener, Mr. Walters), Colesbourne, Gloucester.

SYMPHORICARPUS MOLLIS.

An extremely beautiful Snowberry, and, though there seems to be some doubt as to the correct name of this shrub, there is no doubt at all as to its effectiveness in the garden, when, in autumn, its growths are pendulous with the weight of its crowded white berries. It is a free-growing, hardy shrub, that has been most successfully cultivated for some time at Aldenham, and may well be described as a very much glorified snowberry, as compared with the well-known Symphoricarpus racemosus. The symphoricarpuses are all natives of North America. F.C.C., R.H.S., October 7. Hon. Vicary Gibbs (gardener, Mr. E. Beckett, V.M.H.), Aldenham House, Elstree, Herts.

HELIANTHUS SPECIOSUS.

A very distinct plant that did not do itself justice as shown, the flowers having suffered, apparently, during transit. Four inches or so across, the flower heads suggest a big single zinnia, and the ray florets are of a brilliant orange-vermilion. The stem of the flower is smooth, and for about a couple of

inches below its junction with the flower-head, it is curiously hollow and inflated. We believe the species is of annual duration, and should be referred to Tithonia, a small genus of Mexican and Texan plants. A.M., R.H.S., September 7. Mr. W. Batchelor, Towcester.

CARNATIONS.

Yellow Stone.—An American-raised perpetual carnation that brings us nearer the desired deep yellow variety. It has shapely flowers of fair size, and the colour is yellow, with a few faint white markings. A.M., R.H.S., October 7. Messrs. Allwood Brothers, Wivelsfield, Haywards Heath.

Queen Alexandra.—A beautiful addition to the soft rose-tinted pink varieties, of fine size and shape, with fringed petals, and a faint fragrance, this variety has also a good habit, as evidenced by the plants exhibited. A.M., R.H.S., October 7. Mr. G. Clark, March.

DAHLIAS.

Carl Bechstadt.—A vivid scarlet-red collarette dahlia, the rounded ray florets tipped with yellow, and the collar yellow also. Very effective. A.M., R.H.S.; F.C.C., N.D.S., October 7. Mr. J. B. Riding, Chingford.

General de Sonis.—A fine collarette variety with beautiful crimson-scarlet colouring, and a well-developed, rich yellow collar. Strikingly handsome. A.M., R.H.S.; F.C.C., N.D.S., October 7. Mr. J. B. Riding.

Offenbach.—A very fine decorative dahlia, of good size, and carrying its flower-heads on stiff, erect stems. The colour is rich yellow. The flowers are flattish, a trifle pointed, and they overlap prettily. Should become a popular garden dahlia. A.M., R.H.S.; F.C.C., N.D.S., October 7. Mr. J. B. Riding.

The Quaker.—A pretty cactus dahlia, of soft greyish-blush colour, fading to white at the base of the graceful florets. A.M., R.H.S.; F.C.C., N.D.S., October 7. Messrs. J. Stredwick and Son, St. Leonards.

APPLES.

The Guelph.—A handsome dessert apple, of good size and shape. It is the result of crossing Charles Ross and the Rival. The colour is greenish-yellow, with a thin veiling of russet and a fine flush of red on the sunny side. It is fit for use in the autumn, and keeps fairly well. A.M., R.H.S., October 7. Mr. W. Pope, Newbury.

Peacemaker. — Another good dessert variety, very much like The Guelph, but of more conical shape; in colouring it differs little from its companion. The parents were The Houblon and Rival. A.M., R.H.S., October 7. Mr. W. Pope.

S. T. Wright.—This fine cooking apple bears the name of the popular Superintendent of the Royal Horticultural Society's Gardens, Wisley. The fruits are of large size, pale green, tinted with yellow, and streaked and splashed with red. The variety was obtained by crossing Peasgood's Nonsuch with Bismarck, and we understand it crops well. A.M., R.H.S., October 7. Messrs. Jas. Veitch and Sons, Chelsea.

Cliveden Prolific.—A flattish, ribbed, green apple that appears to be a long-keeping culinary variety. A.M., R.H.S., October 7. Mr. W. Camm, Cliveden Gardens, Taplow, Bucks.

Cleanliness in Fruit Houses.—All trees should be detached from the trellis and carefully washed with a strong soapy solution, in which a few handfuls of sulphur have been placed, a stronger solution being used for the wires and woodwork. If the trees have been free from insects, one washing will suffice, painting the trees with various mixtures often does more harm than good, while two washings, properly performed, will be found better for the trees and safer than painting. When all has been thoroughly cleansed, and any repairs and painting done, fasten the shoots to the trellis, allowing plenty of room, six to seven inches apart being quite close enough. Prick up the surface of the border of undisturbed trees down to the roots and top-dress.—F. Jordan.

SOME GOOD DECORATIVE ROSES.

At every progressive floral exhibition, one is instinctively drawn to the classes for cut flowers arranged either in some floral design, such as baskets or bowls, or as an embellishment to the luncheon or dinner table. The keen and increasing attention these classes receive is partly explained by the fact that they are usually confined to ladies, but even when open to both sexes they appear to give distinction, as they bring into prominence a number of roses whose flowers in general lack the substance of the purely exhibition flower, hence we conveniently group them as garden decorative varieties.

It is notorious that for the purpose under review these varieties are inimitable, for no other flower gives such delightful gradation and combination of colours as the rose, and these single or semi-double flowers are exquisite when lightly arranged by deft fingers and accompanied by artistic perception. It is interesting to examine the position of Rose Irish Elegance in this respect, for its simple beauty appeals to all, and no other rose figures more prominently in competitive displays; its purple leafage and perfectly-formed single flowers, in which yellow, orange, and copper are so delicately blended present a harmony of most exquisite colour, that if the artist but grasps the proper balance of the object aimed at, the result is generally a floral display of incomparable beauty.

Mdme. Pernet Ducher is only a semi-double rose, but the buds are of faultless form, and when these are arranged with partly-opened flowers, the combination is most pleasing. In the bud stage the colour is a deep canary-yellow, and in the perfect flower this is softened to a lighter tint of cream. Another lovely rose of semi-double form is Papa Gontier. In this the buds are unusually long, and coloured intense rose-crimson. The colour however, loses its strength with development, and when fully expanded the colour approaches carmine-rose. In Mrs. Alfred Tate we have a decorative rose of superb quality, wherein those sunset colours are highly developed, and, when associated with purple-coloured rose leaves, the combination leaves nothing to be desired. Mdme. Abel Chatenay is a flower of some substance, but is not too heavy when tastefully arranged, employing a number of buds with the partly-opened flowers; the colour is a pale fawn-pink on the expanded petals, while the centre of the flower is an intense, rich salmon-rose.

The Lyon Rose presents the most subtle colour among purely double roses; in this the chrome-yellow of the petals appears shaded and suffused with varying shades of pink, but under subdued light the combination of colour has more the aspect of orange and apricot, the colour being both intense and of great depth. Duchess of Wellington is another fine decorative rose, of saffron-yellow colour in bud, the partly-opened flowers holding the rich orange in the centre. Rayon d'Or is the most exquisite of all yellow roses, the flowers being of a faultless shade of daffodil-yellow, and lovely in contrast with the attractive foliage. Among the newest roses Sunburst gives long pointed buds of a deep golden-yellow, the centre being rich orange; although of but recent introduction, the good qualities of this rose as a decorative subject are fully recognised.

Mdme. Melanie Soupert has distinct qualities; the flowers are somewhat variable in colour, and with the carmine flush developed on the salmon-yellow petals the flower is delightful, especially when arranged upon the luncheon table. Other good roses that may be mentioned for their decorative qualities include Honble. Ina Bingham, a semi-double flower of purest pink; the buds, flowers, and foliage are alike good. Instituteur Sirdey, with golden-yellow flowers, the buds being a deeper shade of reddish-yellow. Gustave Regis, a thin flower, with long, pointed buds of deep canary-yellow, the centre holding the colour well when open. Dorothy Page Roberts, the colour a delicate shade of coppery-pink, the whole flower being suffused apricot-yellow. Liberty, a deep crimson flower of medium size, the colour being best in bud and when partly opened; it takes second place to Richmond, the latter holding the colour best in the open flower, which is most suggestive of scarlet-crimson.

Roses grown for decorative uses call for lighter pruning than where exhibition flowers are the sole aim, and when the pruning is carried out at varying dates an extended flowering season is enjoyed.

Coombe Court Gardens.

EARLY CHRYSANTHEMUMS IN SOUTH-WEST SCOTLAND.

Generally speaking, this has been a highly-favourable year for early chrysanthemums in the south-west of Scotland. Where early under way, before the drought set in, they have done exceedingly well, but those which were planted late, and in dry soil, particularly where water was scarce, have not been so good. As a rule, however, they have been very fine, colour being especially clear and bright, while the blooms have been large and well formed. One of the finest collections in the south-west, although in a small garden, is that of Mr. Joseph Black, Maxwelltown, Dumfries, and a study of these, together with the plants seen in a number of other gardens, forms the foundation of these notes.

The Masse varieties have, as in former seasons, held their own admirably, and are still grown in very large numbers. Improved Marie Masse has been very good, as also has been Crimson Masse and others. A distinct gain is that named Striped Masse, which is a grand flower of crimson, the petals nicely margined with white, this giving the flowers a distinctly striped appearance. Mr. Black has a very fine plant of this. A notable white early chrysanthemum is Framfield Early White, which is a gem of the first water, with its large, deep, graceful flowers of the purest white, and just such a plant as the enthusiast would go into raptures over. May Greaves, one of the newer varieties, is highly promising, and has good flowers of rosy-pink on a plant about two and a-half feet high, though the height varies under different conditions. That fine chrysanthemum, Marie Mason, which has been so well received of late, has done exceptionally well, and the writer has seen several fine specimens laden with the large, massive blooms of crimson.

A great acquisition to gardens where tall varieties are desired has been that called Golden Glow—quite an appropriate name, seeing that the handsome flowers are of a brilliant golden-yellow. It is somewhere about four feet high under good cultivation, and has stout, sturdy stems, and excellent flowers. By the way, among the older yellows which have been first class this season are Yellow Bird, Sybil, O. J. Quintus, and Horace Martin.

Red Diana is a striking flower, striped, and formed almost like a French marigold,

and red and gold in its colouration. It may be that this district does not suit Crimson Pollie, or that the stock distributed is not good, but Crimson Pollie is not crimson at all, and is a disappointment to all who grow it here. The sport from Lillie, called White Lillie, is doing well, and has all the good qualities of its parent, with good white coloration.

A little tall, it may be, for some tastes, but a really good early chrysanthemum is Mrs. William Copeland. Its colour is described as light crimson, but it is perhaps rather less pronounced in its colour than that implies, possibly owing to seasonal or climatic conditions. White Touraine is a new and very beautiful white variety, which one has seen in splendid condition, as, indeed, has also been the parent Touraine. Le Danube has evidently appreciated the weather conditions, and some plants have given immense purple-lilac flowers. Betty Surtees has greatly attracted the writer, the lovely flowers being of an exquisite silvery-pink. One of the newer varieties, named William Scott, is also highly promising, the flowers being of a fine golden-bronze. Under the name of Cherry I came across a good variety in Mr. Black's collection. This had fine red flowers of delightful colouring, but the plant is a little late this year. It will probably be earlier from early-struck cuttings.

It has been pleasant to see Caledonia so good this year, as some of us were thinking that it was not going to maintain its reputation so well as it now promises to do. A charming little yellow sport from Tottie, called Annie Laurie, which originated in the garden of a local amateur of renown, is proving an acquisition, and would make a charming dwarf pot plant, as well as being excellent for the front row. But for its name, R. Pegg, which has good flowers of a pleasing shade of deep rose, would find favour with many who desire flowers of its colour. Point de Jour has even surpassed its former good qualities, and has been really grand in several gardens, with its large heads of fine blooms. It is most effective when not disbudded. Disbudding, by the way, is not much practised in the district.

Emily Sturt reminds one of the older Normandie, but it has a more massive and solid bloom. It promises to do specially well in a dry season. Marjorie Bailey, though only small plants were seen, looks promising on account of its good colour. The catalogues call it golden terra-cotta, but I should feel disposed to describe it as very deep, but brilliant, orange. Ethel Bellamy is most attractive, the petals hanging gracefully, and the colour a rich rose-pink.

Quite a number of others have been studied, about three hundred varieties, in point of fact, and it is impossible to detail all the best even. Very fine, however, have been Pollie, Improved Pollie, White Pollie, Goacher's Crimson, the richly-coloured Emily Bartlett, the exquisite La Tamise; Hector, magnificent; William Sydenham, not easy to surpass; the fine Helena, chestnut and gold; the orange-yellow Sunstar, the old Vesuve, Dame Blanche, still excellent among the many lovely whites; and the primrose sport from Esperance called Canariensis.

Of great beauty, as a rule, have also been Pluie d'Argent, S. F. Richmond, Eva Williams, Lady Raphael, Mrs. J. Fielding, Hon. Mrs. Lyttelton, Robbie Burns, Firefly, Mabel Adams, Lady Mary Hope, and Jimmie. Such, with many others, are flowers which have come under the observation of the writer, and which he has seen in splendid condition this season.

S. Arnott.

ROSE DANAE.

While the new roses remarkable for the large size and superb form of their flowers that have been presented to public notice during the past summer received a warm welcome and, in most cases, high distinction, the merits of those with flowers of quite moderate dimensions have not been overlooked. So far from this being the case, the small-flowered roses have received much attention from visitors to the shows, and have had their value recognised by the several societies that make awards to novelties. The two beautiful hybrid teas—Moonlight and Danae—raised by that distinguished rosarian the Rev. J. H. Pemberton, are a case in point. These have flowers of a moderate size, and in one case they are single, and in the other are semi-double. The first-named received a gold medal from the National Rose Society, and the second had from that society the next highest award—a silver-gilt medal, while both have had an award of merit made in their favour by the Royal Horticultural Society. We mention this as a proof that garden roses, and these essentially belong to the garden, are readily welcomed by rosarians, provided they possess merit of a high order.

As in the case of Moonlight, which we illustrated a short time since, Danae is a hybrid tea cluster rose, remarkable for its elegant habit and the freedom with which it blooms from June until the autumn is well advanced. The flowers are semi-double, of a soft yellow hue, and have a pleasant fragrance that reminds one of the perfume of the musk rose. The growth is vigorous, the plant producing throughout the season strong growths from near the base four feet or so in length, and bearing clusters of flowers. The foliage is dark green, and is in perfect harmony with the yellow flowers, which, it may be aded, are admirably adapted for association with other garden roses in exhibition collections, as exemplified by the beautiful vases of flowers that Mr. Pemberton had in his two winning collections of decorative roses at the exhibition held by the National Rose Society in September last.

NEW H.T. ROSE DANAE.

Flowers, soft yellow. Raised by the Rev. J. H. Pemberton, Havering-atte-Bower.

Carrots. — The main crop should be lifted at an early date and stored in a cool shed or cellar; if the crop is a large one, the best plan is to pit the larger portion, as was recommended for beetroot. When lifting the crop put aside all undersized and deformed roots for immediate use. Short-horn carrots sown in June or early in July should be left in the ground as long as the weather will allow. Later-sown batches for supplying small roots should be left in the ground and drawn from as required, with, during severe weather, some litter or bracken sprinkled over them.—W. Messenger.

SUCCULENT PLANTS FOR AMATEURS.

(Continued from page 764.)

Crassula.

The genus Crassula is a large South African one, a few species of which are commonly grown. The bulk of them are not of any particular beauty, the exceptions being the well-known C. falcata and C. coccinea, with bright scarlet, and C. jasminea, with pink or white flowers. The two latter species are referred to the genus Rochea by some authorities.

Mesembryanthemums.

The mesembryanthemums, or "figworts," are all natives of tropical or sub-tropical South Africa. They all revel in sunshine, and many kinds will only open their flowers during spells of bright weather. Numerous species are in cultivation, and they are mostly of very easy culture, especially the shrubby kinds. Some of these soon make large bushes, and flower profusely in a light and sunny greenhouse. A few of the best of these are M. Browni and coccineum, with scarlet flowers; M. aureum and edule, with yellow flowers; M. violaceum and spectabile, purplish-red; M. curviflorum and blandum, pink or rose; M. aurantiacum, deep orange; M. conspicuum, red; and M. multiflorum, and numerous others, pure white.

Of the dwarfer kinds, with thick fleshy leaves, a large number are rather rare in collections, and for this reason cannot be included here. A few of the best species obtainable from succulent specialists are M. tigrinum, testiculatum, Salmi, nobile, fragrans, grandiflorum, felinum, minutum, and agninum, all of which have flowers of some shade of yellow.

Mention must also be made of the distinct, and somewhat rare, M. Bolusi, with its curious thick, fleshy, and irregular-shaped leaves, which closely resemble a piece of granite, and bearing an occasional flower of a curious reddish-brown colour.

Stapelias.

The stapelias, or "carrion plants," are a beautiful and distinct class of succulents, mostly natives of tropical and sub-tropical South Africa. They are all of a dwarf tufted or trailing habit, with square, fleshy, erect or spreading stems, leaves greatly reduced, or almost entirely aborted, and most beautiful flowers of various shades of yellow, cream, and red to deep maroon. The flowers are often densely covered with long or short hairs, which greatly enhance their beauty, and a few of the species have numerous and irregular bars, spots, or tubercles on the inside, and occasionally also on the outside of the corolla. As a class they are all of considerable merit, and most of them may be readily managed in a sunny window or greenhouse. They have one peculiarity that, in spite of the great beauty of their flowers, they all emit a most offensive odour for a day or two after the flower opens, resembling that of decaying meat, hence the common name applied to them.

A few species have very large flowers, such as S. Planti, grandiflora, and Barkleyi, but these are rare in collections; the commoner kinds are smaller in size, with flowers from one to four inches in diameter, and, usually, compact habit. A few useful and easily-grown sorts are the following: S. variegata, atrata, discolor, Desmetiana, mutabilis, normalis, reflexa, and trifida.

Echeverias.

The cotyledons, or echeverias, are natives of South Africa and Central America. They vary greatly in habit, and in the degree of succulence. Most of them have thick fleshy leaves, often brightly coloured or silvery or bluish-grey. They require rather more water at the roots than most succulents, and require to be frequently propagated by rooting the tops of the plants, as they grow quickly, and soon become leggy and unsightly. A few of the dwarfer kinds are frequently used for summer bedding, and most of the commoner sorts may be wintered in a cold frame if kept a little on the dry side. A few useful species are as follows: C. agavoides, amœna, secunda, farinosa, gibbiflora and its variety metallica, glauca pulverulenta, and fulgens; a fine variegated plant of garden origin is C. Hoveyi, distinct and pretty, and a few good hybrids are C. Funcki, dasyphylla, mutabilis, and Scheideckeri.

C. P. Raffill.

BEDDING OUT FOR WINTER.

Autumn bedding should not only be planned for the gain of a spring flower show; the winter sightliness of the garden is a benefit well worth securing, especially as it will help, not hinder, the effects of March and April, those months that witness the chief glories of our bulbous plants and bring in also the many-hued wallflower, the azure forget-me-not, and the splendour of violas. Neat little shrubs should be used for centrepieces and to replace the dot plants that have given dignity to summer beds; the varieties suitable are very numerous, for all evergreen subjects may be employed in genial localities, while in the coldest situations miniature laurels and euonymuses are sure to thrive. Charmingly graceful additions to beds are plants of any of the hardy ivies, trained to bamboo sticks, and it should be realised that an ivy plant only a foot or two tall is a lovely object, while older specimens may tower a dozen feet. If ivies were more used there would not be such monstrous levels in garden landscapes during winter.

Apart from shrubs, however, excellent evergreen lines and carpets can be obtained. Dwarf wallflowers keep their foliage fairly well, but many of the 3ft. campanulas offer pretty verdant tufts, and can be left in the beds when bulbs are lifted, to accompany May and June flowers by their blue or white blossoms. London pride will mark out designs of quite intricate character, or clothe stretches of ground beneath trees, enabling pattern planting to be indulged in even there. Mossy saxifrages, with their fine parsley-green, close leafage, are ideal for the best beds, separating species of bulbs, or mingled with myosotises, wallflowers, polyanthuses, double daisies, pulmonarias, and hybrid single or double primroses.

Heucheras continue green during most winters, and their neat habit entitles them to general use; of the merit of plain and variegated arabises there is surely no need to speak; and the eye rests with pleasure always upon the stately spear leaves of German irises. There are no seasons that find pinks other than attractive. Members of the primrose family may become withered as to foliage in hot summer, but their gay green in the dreary season is a boon indeed, even the grey of the auricula possessing merit. While Cerastium tomentosum is well known, few gardeners make use, as they should, of the earlier-blooming Cerastium arvense compactum, the feature of which is its close, prostrate, green foliage. Thrifts are valuable, and so are the sandworts, Arenaria balearica, and A. laricifolia, which give verdant carpets. Then acænas, or New Zealand Burs, are dwarf evergreen plants willing to flourish even beneath cedar and cypress trees.

No one who has seen clever winter bedding done, with even the most ordinary shrubs and plants, will ever again desire that all the ornamental portions of the garden shall be given up to bulbs that afford no show until spring is advancing. A two-foot or three-foot bushy Berberis aquifolium, surrounded by dwarf wallflowers alternated with polyanthuses and edged by a line of pinks, will fill a bed excellently. Another bed could contain pattern-forming lines of London pride, in single tufts, dividing spaces filled with double daisies, stachys, and variegated arabis, with German irises at the corners, and a pillar ivy for centrepiece.

Extreme neatness should characterise winter bedding; any encroachment of one plant on another, any unevenness of shrub clipping, will ruin the display. Among most of the lesser plants that clothe the ground, such as saxifrages and arabises, bulbs may be freely planted in November; tall red or pink tulips look their best springing from these underlings, blue and rose hyacinths, too, or the early narcissi and trumpet daffodils.

A final idea for affording colour in winter beds in small gardens is to make lines of stones, temporary rockwork, in fact. In a dark, shaded spot groups or lines of pure white rocks are, with a few shrubs around them, very welcome to the eye. M. H.

A GREENFLY MYSTERY.

Although the life history of the greenfly or aphis tribe is now thoroughly known to entomologists, and every plant grower is only too familiar with its remarkable faculty of rapid reproduction, it often appears under circumstances that are extremely puzzling to the student of plant life.

In my own experience, for instance, I have sown fern spores from plants certainly devoid of aphis life. These spores were sown on soil sterilised by baking or by copious saturation with boiling water. After the sowing it may be weeks or even months before the spores produce the little green prothalli or scales, from which the fern proper arises again, after, it may be, a considerable lapse of time. All through this time pans will have been constantly covered close with glass, certainly precluding the advent of the egg-laying winged generation of the aphis, and yet, over and over again, as soon as the little fronds appear, young aphis have been found upon them, though it is absolutely impossible to believe that aphis eggs were associated with the spores, since it is my rule to allow the spores to be shed on to a glass slip, and to examine them under a fairly high-power microscope prior to sowing.

Another fact difficult to account for is that ferns with creeping underground stolons, the young fronds of which push through the soil irregularly, are not infrequently found to be covered with young aphis directly they emerge, though the previous season's fronds have died down long ago, and been entirely removed. Moreover, when this occurs, it is found that every frond, though it may rise quite separately and well away from its neighbours, will have its pernicious aphis accompaniment. In these cases it is true that the soil has not been sterilised, since that has been impracticable; but the previous season's fronds having been removed, it is difficult to conceive how eggs have remained, and the only conclusion is that individuals have wintered somehow on the underground stolons.

C. T. Druery, V.M.H.

DAHLIA TRIALS AT DUFFRYN.

The dahlia, as so well exemplified by its wondrous diversity of form and colour, has undergone many changes since its introduction to this country, and it has had a somewhat chequered history as a cultivated plant. From the first it received unremitting attention from the large band of florists who were attracted by the distinctive character of the flowers, and, as the result of their strenuous endeavour in the work of improvement, a complete transformation in the flowers was effected. As so well known to those who are acquainted with the historical aspects of the dahlia, the flowers of the plants that were raised from the seed that first reached the British Isles were single, and within three or four decades the flowers had not only become quite double, but had closely approached the ideal that had been adopted. By this time two distinct types had obtained a place in gardens, one the decorative, and the other the show section, and dahlias were largely grown for beautifying the garden and for the production of blooms for exhibition.

Concurrently with the continuous improvements in the form of the flowers in accordance with the ideals of the old florists, and the development of quite new colours, the popularity of dahlias increased by leaps and bounds, and many were the societies established for the purpose of affording encouragement to raisers and cultivators. For half a century or so after the dahlia had obtained a place in British gardens, the attention of raisers was concentrated on the development of show varieties with the object of increasing the size and improving the form of the individual blooms. If a decorative variety possessing sufficient merit to justify it being distributed through the usual channels of trade was obtained, it was an accidental occurrence. The object of the raisers was to obtain flowers that would be suitable for competitive purposes. Then, as at much later periods in the history of the dahlia, comparatively little consideration was given to the habit of the plants, and, if show varieties proved useful in the garden, as unquestionably a considerable proportion of the finer forms did, it was because Dahlia variabilis and its variety coccinea, from which they had descended, were free from some of the defects inherent in Juarezi, the progenitor of the cactus varieties. By the time this last-mentioned dahlia made its appearance in this country the owners of gardens who were not specially interested in the exhibition side of the dahlia cult had become tired of the formality characteristic of the blooms of show and fancy varieties, and, indeed, of the pompons also, and the newcomer was hailed with delight.

The great interest evinced in Juarezi was such as to induce many to enter on the raising of dahlias with cactus-like flowers with much spirit, and from the exhibition point of view with not a little success. Following much the same lines as their predecessors, raisers devoted the greater share of their attention to the production of varieties bearing blooms of a size and form that rendered them of special value to competitors at the public exhibitions. The splendidly developed blooms, when tastefully arranged, were so highly attractive as to at once receive attention and evoke admiration, and it is not altogether surprising that considerable numbers should have been selected by amateurs from the exhibition stands for beautifying their gardens. They, indeed, did exactly what many hundreds of rose lovers did in bygone days; they purchased varieties admirable in their way but unsuitable for garden decoration, and experienced much disappointment. Owing to the robust growth of the greater proportion of the earlier cactus varieties and the shortness of the flower stem, the blooms were more or less hidden from view, and the plants incapable of rendering material aid in the production of colour effects. The raisers were by no means wholly to blame for so few of the cactus dahlias being really suitable for the garden, for those responsible for making awards to novelties attached but little importance to the length and rigidity of the flower stems, and it is probable that, until within the past few years, but few really good garden cactus would have been purchased even had they received awards.

Within the past decade the garden has been enriched by a considerable number of pæony-flowered dahlias, which, owing to the large size and distinct form of the blooms and their effective colouring, at once attracted attention, and were not long before attaining a high degree of popularity. A considerable proportion of the varieties that were introduced during the earlier stages of development were tall in growth, and had flower stems of sufficient length but not strong enough to carry their blooms well beyond the foliage. The desirability of greater rigidity in the flower stems has been fully recognised by the leading raisers, and their improvement is

VIEW IN THE DAHLIA GARDEN AT DUFFRYN.

The variety in the foreground is Gluchant, in the centre Brentwood Yellow, on the left Marianne, and on the right Mertensen.

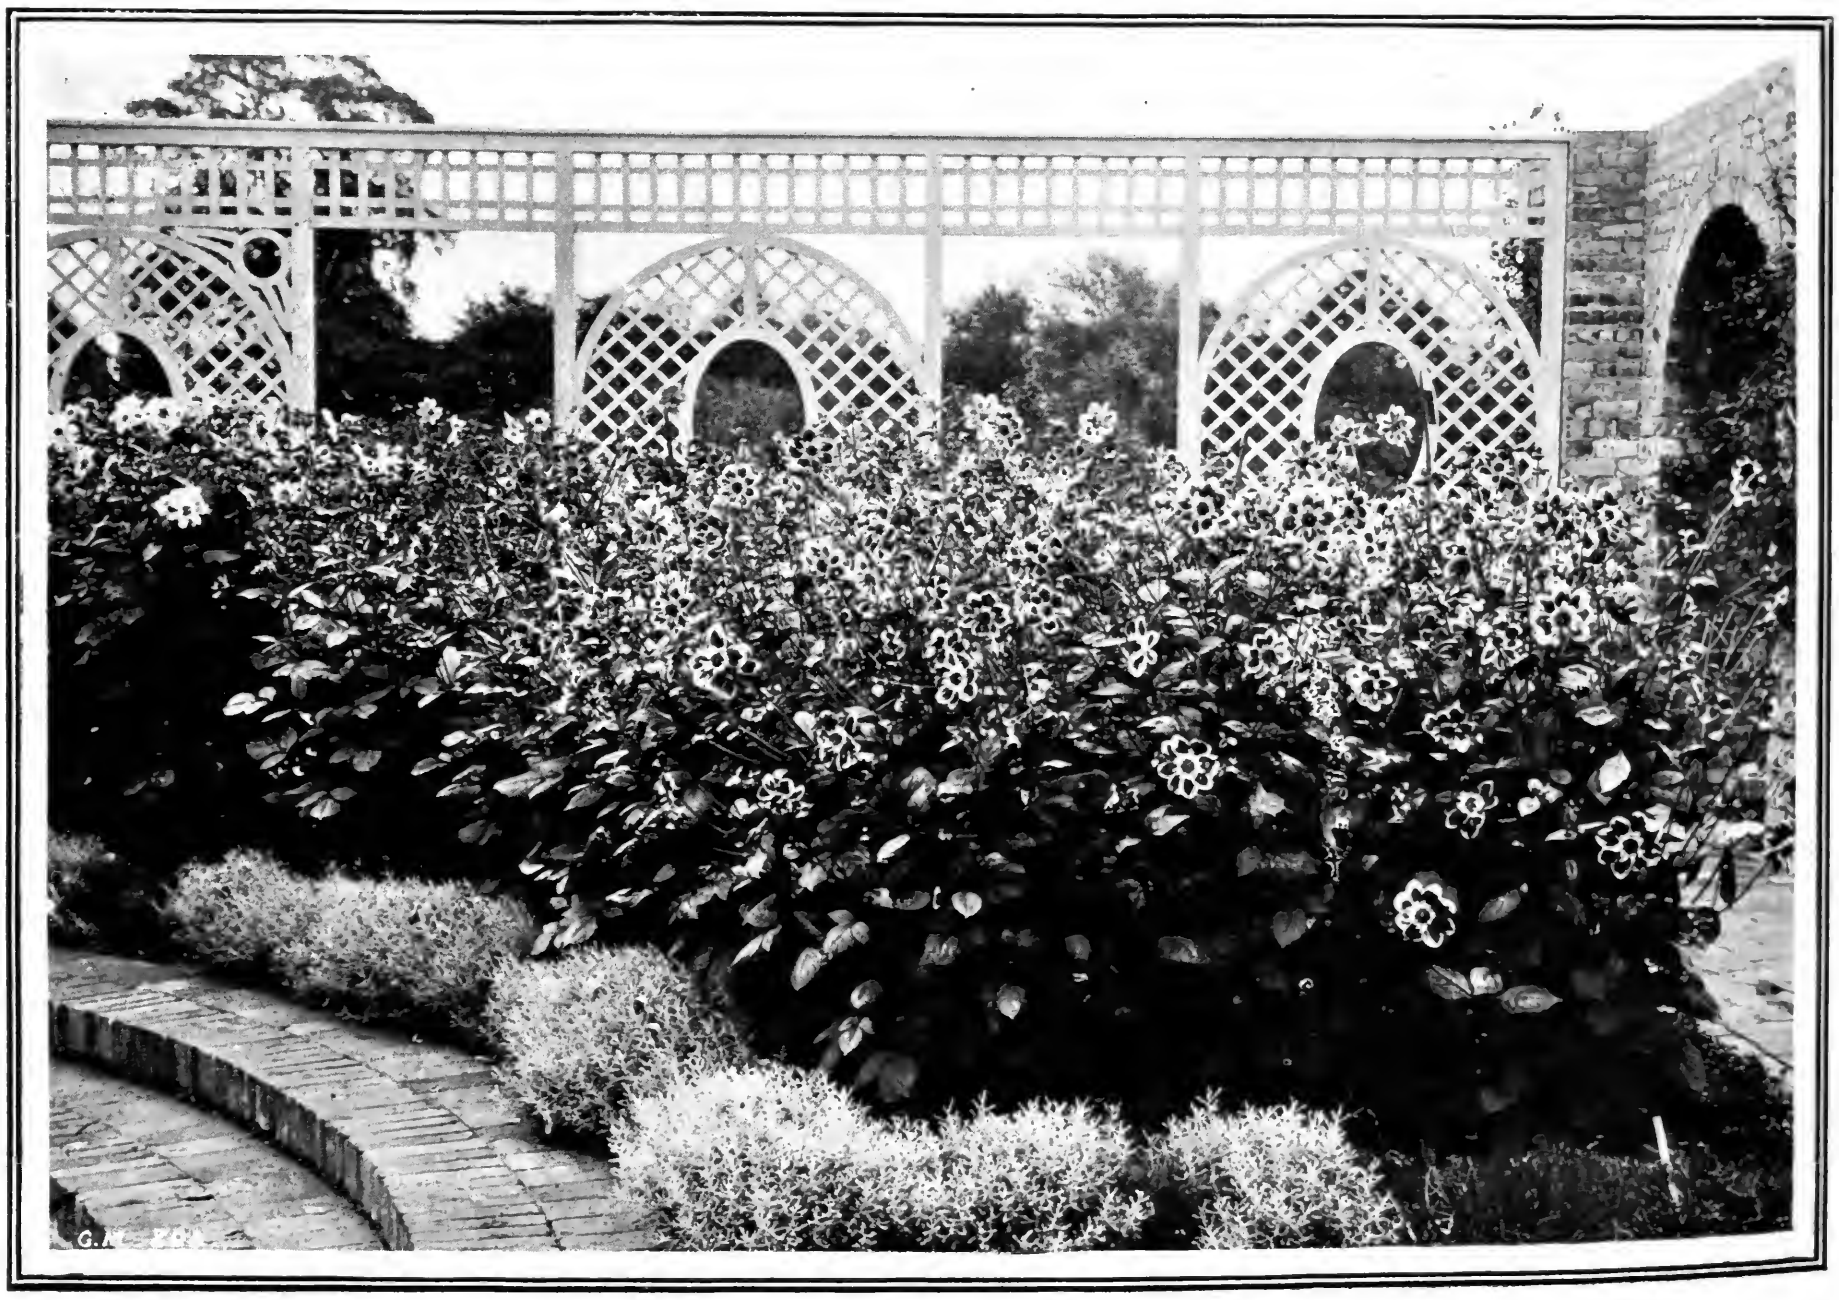
now proceeding so rapidly that at no distant date there will be no cause for complaint of their weakness. In like manner there has been a marked improvement in the decorative varieties, a considerable proportion of the newer forms having flowers that possess much beauty, and are borne on stems that carry them well beyond the foliage.

The immense improvements that have, from the decorative point of view, been made in dahlias has materially increased the difficulties of making the best possible selection. This fact has not escaped the attention of those who take a broad outlook of the position of dahlias in the flower garden, and it has been recognised that only by a comprehensive and careful trial could the finer varieties be given the requisite degree of prominence. It was felt also that the carrying out of an adequate trial would be so stupendous a task as to be almost impossible of accomplishment by existing organisations. Immediately after an agreement had been arrived at upon this point, I received, by virtue of my position in the National Dahlia Society, an intimation from Mr. Reginald Cory that he proposed conducting trials of garden dahlias at Duffryn, near Cardiff, and was desirous of obtaining the co-operation of the society. The proposal was received with the warmest expression of approval, and the promise was at once given that the National Dahlia Society would heartily co-operate in the bringing to a successful issue so important an undertaking. Similarly the Royal Horticultural Society at once promised their co-operation, and this was given in the heartiest manner.

These preliminaries having been arranged, Mr. Cory issued an invitation to raisers and cultivators to send for the purposes of the trials plants of such varieties in the several sections as they considered suitable for garden decoration. The response was so generous that it must have been somewhat embarrassing, notwithstanding the resources of the Duffryn gardens. When the last package had been received it was found that the collection included about 1,000 varieties, and the number of plants exceeded 7,000. Had the latter been allowed to remain in the small pots in which they were received, or, in the case of the home-raised stock, in the pots in which they were first put, it would have been no light matter to deal with them. But it is not the practice of Mr. Cobb, the able gardener at Duffryn, to subject dahlias to the starving process with which we are so familiar, prior to bedding them out. The importance of strong plants at this stage is fully appreciated, and as these cannot be obtained without the aid of ample root-space and a substantial compost during the preparatory period, they were all shifted into larger pots. For a few six-inch pots were used, and the remainder were given pots nine inches in diameter. Hence, when bedded out, they were strong and well advanced in growth, and made rapid progress. As the result they came into bloom at a comparatively early period, and flowered freely and continuously throughout the season.

As upwards of 7,000 dahlias require a considerable area for their full development, it is a point of some interest, as indicating the large extent of the beautiful gardens of Duffryn, that they were given ample room for their development without appearing to appropriate any considerable proportion of the area of the pleasure grounds. Within the forty or more acres comprising the ornamental features there are several gardens devoted to specific purposes, and these are so arranged that, while fitting into the general design, they can be readily reached or omitted, as may be desired, in a tour of inspection. This arrangement very closely approaches the ideal in garden-making, and one would like to make some reference to the specific gardens, but it is now impossible to do justice to them. Suffice it to say that one of them is devoted to dahlias, and that from the first it has been one of the centres of interest and attractiveness throughout the summer and a considerable part of the autumn. A portion is shown in one of the accompanying illustrations, and, as will be seen, contains a central bed furnished with that fine decorative variety Brentwood Yellow, surrounded by four other beds containing pompon cactus dahlias, among which the brilliant scarlet Gluchant is very conspicuous. Beyond these are raised borders devoted to the remarkably attractive collarettes. The garden is having large additions made to it, and on the eastern side a considerable area has been devoted chiefly to decorative pompon, and show varieties. On the southern side a still larger area is wholly occupied by pæony-flowered varieties, which have produced a glorious display. On the western side is a broad stretch of lawn bounded by spacious shrubberies formed with the choicest kinds. Along the front are borders for summer-flowering plants, and this year they are occupied by garden cactus dahlias. By this arrangement, the greater part of this closely-shaven lawn is enclosed in a belt of dahlias, and the display of flowers has been not only highly attractive, but of much interest as demonstrating how considerable is the number of really good cactus dahlias for garden decoration.

The determination of the relative merits



BORDER OF COLLARETTE DAHLIAS AT DUFFRYN.
The variety so prominent to the right is Henri Farmer.

of the varieties in the several sections was, as already recorded in these pages, entrusted to a joint committee of the Royal Horticultural Society and the National Dahlia Society, and this committee visited Duffryn during the first week of September last, and spent two whole days in the performance of their pleasant but onerous duties. My engagements prevented me joining the joint committee at Duffryn, but, on the invitation of Mr. Cory, I went down a fortnight later, and the two days I had among the dahlias afforded much pleasure and were full of interest. The results of the work of the joint committee will be published in due course by the two societies, and for these it will probably be necessary to wait some time.

I also made notes of some of the more noteworthy varieties in the several sections, and, with the co-operation of Mr. Cobb, who is fully acquainted with the characteristics of the immense number of varieties in the collection, have been able to prepare a short list that cannot fail to be of value to those who are anxious to grow a few of the best of the several types. Especially noteworthy among the better-known of the decorative varieties are Delice, a charming form with flowers of a rich pink hue; Loveliness, bright yet soft pink, and so beautiful as to fully merit its name; Princess Juliana, pure white; Jeanne Charmet, bright heliotrope; Brentwood Yellow, dwarf in growth and bearing a profusion of large, soft yellow flowers; and Kaiserin Augusta Victoria, creamy white, an exceptionally useful variety for beds. A few highly meritorious varieties that are not so well known are Charming, a new variety with lovely pink flowers; Harmony, pale pink; Perle de la Tête d'Or, a very fine dwarf white variety; and Lagdina, crimson shading to white, a lovely flower, borne on a good stem. Some of the best of the giant decoratives are Papa Charmet, deep crimson; Phenomené salmon; Le Grand Monitor, flaked purple; F. Grimsted, yellow striped red; Ulysses, crimson, dwarf; Souv. de G. Douzon, scarlet; Yellow Colosse, yellow; and Mont Rose.

Very effective among the cactus varieties were Conquest, deep crimson maroon, probably the best of the dark varieties for the garden; Effective, lemon colour, very free flowering, and one of the most valuable for the garden; Erecta, a rather deeper shade of pink than Sweet Briar, and very good; Hon Mrs. A. Greville, orange-yellow suffused salmon; Mauve Queen, clear mauve; Miss Willmott, golden-yellow; Mrs. Forester Paton, scarlet, early, free, and continuous in flowering, very fine; Mrs. Lonsdale, yellow edged with rose, a pleasing combination; Mrs. H. Treseder, bronze-yellow, the florets tipped pink, one of the very best; Salmon Queen, bright salmon; Star, bronze-yellow; Sweet Briar, pink, the best of its colour, but late in coming into bloom; White Ensign, white, this has the best flower-stem of the white varieties, but is not so pure as Mrs. Douglas Fleming or Snowdon, and is later in coming into bloom; Vivid, scarlet, dwarf, and good; and Westhall Scarlet, a good variety in its colour. The following are a few of the best of the pompon cactus varieties; Gluchant, scarlet, very free; Gracie, yellow tipped scarlet and white; Miss Hicks, crimson; Magenta Queen, magenta; Niobe, yellow, very good; and Queen of Pinks.

The Pæony-flowered varieties, which have formed so glorious a feature at Duffryn, include the following, all of which are of special merit: Bayard and Geisha, scarlet and yellow, both very attractive; Balak, soft dark red, fine habit; Garibaldi, crimson, the height ranging from four to five feet; Ladysmith, deep rose; Liberty, London, scarlet; Holman Hunt, a grand crimson, tall; John Green, a new variety of exceptional merit, the blooms are large and attractively coloured scarlet and yellow, and are borne on stems of good length; King Leopold, the best tall pale yellow; Mrs. Kerr, cream-white striped pale pink; Mrs. T. G. Baker and Princess Ida, white; Paul Kruger, cream-white, heavily splashed and striped rose-crimson; and Warrior, deep red, fine habit. The dwarfer varieties in this section include many that possess much merit, the following being very fine: Colonel Cody, buff; Frau Anne Galster, bronze-yellow; Kahadee, unique, pale yellow, with long cactus-like florets, habit not perfect; May Day, a lovely variety, the habit good, and the flowers are large and borne on good stems clear of the foliage; the white striped rose-pink should be included in the smallest selection. Miss Walton, white striped rose, very fine, and most effective; Lord Milner, pale yellow striped and suffused rose-pink; Mrs. George Gordon, lemon-white, flowers large and borne on good stems, Primrose Queen, a fine yellow; Red Indian, rich deep red; Reynolds, a grand crimson variety; Romolo Piazzani, yellowish-salmon; and Viscount Newport, orange-red, flowers small but freely produced.

Although but few regard the show and fancy dahlias of value for garden decoration, it must be stated that Canary Bird, yellow; Duchess, scarlet; Edward Mawley, crimson; Harbinger, peach; Miss Ormerod, rose-peach; Peacock, crimson and white; Queen of the Belgians, delicate pink; Tom Jones, cream edged rose; and Sunbeam, are wondrously attractive when grown, as at Duffryn, under conditions favourable to flower production.

SHOW AND FANCY DAHLIAS AT DUFFRYN.

The variety in the foreground is Goldsmith, immediately behind is Queen of the Belgians, and on the left David Johnson.

The pompons included in the trial that are of special excellence comprise: Bacchus, scarlet; Crimson Beauty, Evellyn, crimson; Firebrand, scarlet; Glow, coral-red; Horace, purple; Ideal, yellow; Neatness, cream and salmon; Queen of Hearts, pure white, very fine for beds, and valuable for the supply of cut flowers; Tommy Keith, red, tipped white; Virginia, white. The most effective of the single varieties are: Cardinal, rich red; Crimson King, crimson; Hilda, flesh with yellow margin; Mary, crimson margined salmon; Mikado, centre scarlet with outer band of yellow; Mrs. Hood, yellow; Owen Thomas, scarlet tipped yellow, very striking; Peggy, rose-crimson, purple and orange; Rosemary Bridge, deep rose; and Rosy Gem, bright rose.

The great value of the collarettes for garden decoration has been amply demonstrated in the Duffryn trials, and their splendid habit, freedom of flowering, and effective colouring suggest their attaining a high degree of popularity. The first two characteristics are well shown in the accompanying illustration of one of the borders devoted to the section. The finest of the older varieties are Comtesse Duzon, Diadem, Goldstein, Henri Farmer, Holyrood, Le Congo Belge, Maurice Rivoire, Negro, Prince de Venosa, and Queen Bess. New varieties of promise included Cambrae, Lynas, Prince of Orange, and Regularity.

The varieties enumerated form a thoroughly representative selection, and those who purchase and plant them will have varieties that rank high in their several sections and are capable of contributing in a lavish manner to the attractions of the flower garden. One would like to refer to other points of interest in connection with this remarkable trial, but the available space will not permit of more being done than to congratulate Mr. Cory on his judgment and public spirit, and Mr. Cobb on his skill in carrying out the cultural details.

George Gordon.

BRONZE AND TRICOLOR PELARGONIUMS.

I was very much interested in reading the note on these plants (page 709, September 20) by "W. T."

Twenty-five years ago, when I served in Lathom House Gardens, Ormskirk, Lancashire, the then head gardener, Mr. James Hathaway, grew hundreds of tricolors, and used the plants most effectively in the flower garden—in carpet bedding combinations and also in beds by themselves.

In order to bring out the rich colours in the leaves the plants were grown in rather small pots, and the potting was done as early as possible so as to get the pots well filled with roots by bedding-out time. Once, I remember, late potting was tried in spring, but the plants were not benefited, the colour in the leaves was less intense, and it was rather indifferent throughout the summer season. "W. T." refers to these plants being grown as specimens. The finest I have seen were grown by an amateur cultivator, and they looked charming in his greenhouse. They were very old specimens, too.

I used these tricolors extensively for edgings—broad ones—to large beds which were filled with groundwork flowering plants and others as dot plants, and found such arrangements successful. In many gardens there are raised beds in very warm positions and the tricolor pelargoniums do well on them.

George Garner.

POMPON DAHLIAS AT DUFFRYN.

The varieties are: In foreground, Glow; on left hand, Tommy Keith; and beyond the first-named, Irene.

VERONICAS.

Veronicas are not only free-flowering border subjects, but very beautiful foliage plants also. Many border plants, when given good treatment, fail to branch out well near the bottom of the main stem, and then it is necessary to put in other kinds of plants to "front up," as it were, and thus hide the bare stems. In the case of veronicas there is no trouble in this respect at all. They grow compactly, but not too closely and stiffly.

The period of flowering extends from June to October. Indeed, in mild winters in the southern counties I have seen plants bearing flowers throughout those months. At the present time—beginning of October—I have just seen many plants bearing flower-spikes that are beginning to develop, and promise to be in full flower in December.

As rockery subjects, veronicas—especially those of creeping habit—are very charming. It is difficult to name a position in which the plants will not grow and thrive. In a sandy soil, a medium loam, and on dry borders they flourish. The only soil they fail to grow quite satisfactorily in is a cold clayey one, and under the shade of tall trees.

Veronicas are charming border subjects for growing near the sea coast, and do remarkably well in gardens in seaside towns, especially where a sandy soil prevails.

Veronica spicata, which has erect stems bearing bluish-violet flowers, is a general favourite, but I like the variety longifolia rosea, with its lovely rose-coloured flowers. The deep blue of V. subsessilis is very pleasing, also, and V. alpestris must be included. V. alba, pure white, is a good one, as also are V. rupestris and V. repens for rockeries.

G. B.

KELWAY'S

LOVELY DELPHINIUMS

Kelway's Delphiniums grow to a height of from four to eight or more feet and bear masses of fine shapely blooms in all shades of blue and purple. They thrive with a minimum of attention in almost any soil and situation, and they provide a bold and beautiful show either massed by themselves or as a part of the Kelway Colour Border.

KELWAY COLOUR BORDER (Regd.)

To secure absolute perfection in your Herbaceous Border, stock it with Kelway Hardy Perennials. Their bold forms and lovely colours represent the outcome of years of patient experiment and hybridization, while they are raised from such strong country-grown stocks that they may be depended upon to flourish under almost all conditions of climate.

NOW IS THE TIME TO PLANT

FRUIT TREES.

A specially fine stock fit for immediate planting. Awarded two Gold Medals, R.H.S., Autumn, 1912, Also first prize in open class. Autumn, 1913.

Hardy Flowering and Ornamental Shrubs.

Gold Medal awarded Royal International Horticultural Exhibition, 1912.

A PRESS CRITICISM.

"BULBS AND THEIR CULTIVATION," by T. W. Sanders, illustrated (2s. 6d., W. H. and L. Collingridge), is a vade mecum for every grower of these beautiful flowers. To possess a copy is to gain knowledge and save money in the prevention of errors in cultivation. Two shillings and sixpence spent therein will probably save pounds in other ways. We have nothing but praise for this excellent work.

YOU CAN GROW

Bulbs with ease and success if you study the New and Enlarged Edition of

BULBS

AND THEIR CULTIVATION

By T. W. SANDERS, F.L.S., F.R.H.S.,
Editor of "Amateur Gardening."

EVERY SORT OF BULB, AND EVERY METHOD OF CULTURE IS SIMPLY EXPLAINED,

so that no matter whether
YOU DESIRE TO GROW THE STATELY LILIUM OR HOMELY BLUEBELL
herein you will find
THE BEST VARIETIES TO GROW, THEIR CULTIVATION IN BOWLS, BEDS or BORDERS, PESTS and REMEDIES.

THE BOOK IS WELL PRINTED AND DELIGHTFULLY ILLUSTRATED.

YOU CAN OBTAIN A COPY THROUGH ANY BOOKSELLER OR BOOKSTALL,
or direct from our Publisher by filling in the Order Form below.

ORDER FORM.

To the Publishers, 148 & 149, Aldersgate Street, London, E.C.

Please send me, by post, **"BULBS AND THEIR CULTIVATION,"** *for which I enclose* **2/10.**

FLOWERS IN THE SOUTH-WEST DISTRICT.

For the first four months of the year the rain was exceptionally heavy, 24.78 inches falling in that period, the heaviest fall for the four months that has been recorded for fifteen years. Since that time the weather has been very dry, less than an inch of rain being registered during the months of June, July, and August respectively. In June rain fell on eight days, but only once exceeded a quarter of an inch. In July there were only five days on which rain fell, and in August six days. The total fall for these three months was only 2.30 inches. In July there was a period of twenty days in which not a drop of rain fell.

In the garden the spring was very early, Gladiolus tristis being in full flower at the end of March, considerably earlier than is usually the case, as it never, as a rule, blooms before April. This beautiful flower, of a uniform pale yellow, does not appear to be in the hands of any nurseryman, as those who catalogue it invariably send out corms the flowers of which have purple stripes in the centre of the three upper petals. The pale yellow form is known as Gladiolus tristis concolor, and, as I have been able to provide some nurserymen with seed of it, in a few years' time it should be procurable from the trade. Being informed by a friend that this gladiolus appreciated manure, the corms were lifted and planted eight inches below the surface above manure a foot deep, and one will be anxious to see how they prosper under this treatment.

Œthionema pulchellum flowered splendidly in the late spring, but last year, from some unexplained reason, a plant of this species, and one of Œ. grandiflorum, died when in full bloom. Clematis tangutica behaves in a most extraordinary way. Early in February it becomes green, but late in March the leaves wither, and by early April the plant appears dead. About the end of May, however, green leaves are again put forth, and it continues to grow and flowers in July. It has behaved in this manner for the past three years, and, although I have consulted several experts, no one has been able to account for this strange behaviour. Clematis indivisa lobata was a glorious sight in March and early April, a plant covering a space of six feet in height and forty feet in length, being a simple sheet of flower.

Daphne Blagayana, with all its shoots pressed into the ground by stones, flowered well in the spring, as did the beautiful D. cneorum. Osteomeles anthyllidifolia was very pretty when bearing its clusters of white hawthorn-like flowers, and appears quite hardy, as it is said to thrive in the open in Oxfordshire without protection. It was discovered in China by the Abbé Delavay. In March Edwardsia (Sophora) Macnabiana was covered with yellow flowers. This species and E. grandiflora appear to be fairly free flowerers, but E. microphylla very rarely blooms in this country. Carpenteria californica was very handsome when in full flower, as was a large specimen of Drimys Winteri.

Solanum crispum having grown too tall has been cut back, but is breaking strongly low down. Atragene alpina has increased considerably in size, and flowered well, as did the handsome Tricuspidaria lanceolata, better known as Crinodendron Hookeri; while Tricuspidaria dependens bore a fair quantity of white blooms, but cannot for a moment compare with its relative for effect. Callistemon salignus bore a profusion of its red bottle-brushes, but C. lanceolatus did not flower this year. Plagianthus Lyalli, which was received from New Zealand as a small rooted cutting, about six inches high, is now a tree over 12 feet in height, and flowered abundantly this summer. A variety named grandiflora was planted two years ago, but has not flowered yet. The leaves are, however, absolutely distinct from those of the type, so the blooms may also vary.

The New Zealand Arthropodium cirrhatum flowered poorly this year, though in former seasons it has borne a dozen or more bloom-spikes. Echium callithyrsum bore tall, blue-flowering shoots in March, but it is a very tender plant, and is generally badly damaged in a hard winter. Lathyrus pubescens, growing against a south wall, reached a height of over seven feet, and bloomed profusely, though whether it will come through the winter remains to be seen. Salvia dichroa, from the Atlas Mountains, was very fine, exceeding eight feet in height, and bearing its tall purple and white flower-spikes in quantity. This plant, I believe, is not offered by any nurserymen, but is extremely handsome. Abelia floribunda, against a south wall, was a sheet of colour in the spring, and a large mass of Androsace lanuginosa about a yard across has been flowering all the summer.

One of the most beautiful plants in the garden has been the rare Dierama (Sparaxis) pulcherrima alba. A group had over two dozen tall, arching flower-wands, each set with from eight to ten drooping clusters of pure white blossoms, and created a most lovely picture. This plant is only catalogued by one nurseryman, who lists it at 3s. 6d. a bulb. Watsonia coccinea perfected its scarlet flower-spikes in the late spring and early summer, and W. Ardernei threw up a dozen flower-scapes of the purest white early in August; but W. rosea did not bloom. A plant of Cypripedium pubescens bore over two dozen flowers, and, later on, C. spectabilis flowered well, as did the rare Wulfenia Amherstiana. Ourisia coccinea, watered very freely in dry weather, succeeded admirably, and bore several dozen brilliant scarlet flower-heads, and was a beautiful sight when in full bloom.

A group of Dictamnus fraxinella alba was very handsome when in flower, and in August Francoa ramosa bore its tall white spires of bloom. This Chilian plant appears perfectly hardy here. Bowkeria Gerardiana has never flowered so well as this season, and was full of bloom. The specimen is eight feet in height, and as much through, and is probably the largest example in England. It is a very rare shrub, and is scarcely ever met with. Lonicera Hildebrandiana came into flower early in August, and bore quite a hundred bloom-clusters. It is growing on a north-west wall, where it gets about three hours' sun in the day, but it never fails to bloom freely. The plant is eight feet in height and six feet across. The blossoms are six inches in length and five inches spread at the mouth. They are at first white, but turn to a bright orange, and are most deliciously scented. Lonicera syringantha is another very pretty honeysuckle with extremely fragrant flowers.

Convolvulus tuguriorum, a very rare New Zealand plant, bore its white flowers, two inches across, in the early summer. It is almost unknown in English gardens, but is a very attractive subject. The new Chinese Thalictrum dipterocarpum, with maidenhair-like foliage, threw up a flower-stem three feet high, the small, pink, yellow-centred flowers being very pretty. Gerbera Jamesoni flowered fairly well, and the uncommon Campanula punctata produced masses of blossom. Ipomæa rubro-cærulea, started in heat in May, came into bloom in the open in July, and has now reached a height of seven feet. The rare Lobelia laxa perfected its scarlet blooms in the early summer, a fine plant of Olearia insignis flowered well, and a seedling is making fine growth. Solanum aviculare is bearing its large violet-purple flowers with their golden centres, and is covered with fruit, from which self-sown seedlings will probably appear. It is far tenderer than most New Zealand shrubs, and is almost invariably killed in a hard winter.

Bouvardia triphylla has been a sheet of scarlet for the past two months, and the Australian Candollea tetranara has been bearing its yellow blooms. This plant was cut down to the ground and apparently killed in the severe frost of February, 1912, but subsequently broke from the roots again and is now a fine little shrub about two feet high. Cyrtanthus lutescens and C. McKenni have come into flower in a narrow, well-backed border; and Manettia bicolor is blooming finely on a wall. Clethra arborea, which was nearly killed in the severe frost alluded to, came into bloom early in August, and Trachelospermum jasminoides has flowered well. Cassia corymbosa has commenced its flowering period, and will carry blossoms until Christmas.

Of the sisyrinchiums, S. bellum has been a marvellously lovely sight, being absolutely covered with blue flowers; and S. chilense and S. iridifolium have bloomed well. Asparagus deflexus has mounted the wall to a height of several feet, and the Lapagerias, red and white, are now in flower on a north-west wall. Montbretia Prometheus is in fine flower, and the rare Crinum Moorei variegatum has perfected several flower-scapes of white blossoms. A little plant of the newly-introduced Leptospermum Nichollsi is making good growth, and an extremely interesting plant is Campanula isophylla variegata, whose lavender-blue blossoms are prettily set off by the marbled foliage, which hangs over a two-foot rock. Mitraria coccinea has been a glorious sight, having been covered with its scarlet urn-shaped flowers.

Wyndham Fitzherbert.

Kingswear, Devon.

WESTMALINE SYSTEM OF PLANT CULTURE.

Mr. C. E. West, of Higham Hill, N.E., sends us a lengthy article on what he describes as the "Westmaline System of Plant Culture." Mr. West declares that he is the sole inventor of this new system, and then proceeds to state that. "At the present time, it is the one belief all over the world, that all vegetation, including wild and cultivated plants, feed on ingredients found in the soil, or compost, in which they grow. On this belief millions of pounds are spent on manures every year. This I state to be a false doctrine; for all vegetation lives on the four organic elements contained in water, air and light. The mineral elements in the soil are only present as deterrents to fungoid and insect pests, the soil thus only acting as the best receptacle for retaining the water and air." Neither students of plant physiology or practical cultivators are likely to accept Mr. West's views on the manner in which plants obtain nutrient matter.

Amaryllis.—Most of the bulbs used for flowering during the spring and early summer months are now becoming well ripened, and as the foliage dies down they may be stored under the stage of a cool house, laying the pots on their sides that there may be no possibility of their being watered by drip from the plants above. Later batches, and, indeed, any that still have green leaves, should be kept in the full light, preferably on the shelf of a moderately heated, airy structure, gradually reducing the water supply until finally rested. Store with the earlier plants. Seedlings raised in the spring or summer of 1912 may be kept in a growing condition within the intermediate house, and if considered necessary, give them a top-dressing. Under judicious treatment a fair percentage of these may be expected to flower next year. Those raised from seed this year should be kept growing on the stove shelf, and when sufficiently rooted be shifted into 54's. Care must be taken in watering that the soil does not by any chance pass into a wet and sour condition.—H. Prime, Hatfield House Gardens.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

LÆLIAS.—The small-growing lælias, such as L. præstans, L. pumila, L. Dayana, and their numerous varieties, are among the most interesting and useful of our autumn-flowering orchids. They are exceedingly decorative, and make a fine display when in bloom while suspended near the roof-glass in the intermediate house. The growths are now rapidly developing, and the flower buds are produced with the expanding leaves. As the plants are now in their most active stage of growth, every help must be afforded them to develop and satisfactorily expand their flowers. Suspended as suggested they will receive the full benefit of all available light; they must receive ample root moisture, and be protected from attacks of scale and other pests. Any repotting that may be necessary should be attended to as the plants pass out of flower. Afford ample drainage and only a shallow depth of potting compost; select good fibrous peat, of a lasting nature, so that repotting may not be needed frequently.

SOPHRONITIS GRANDIFLORA.—In the cool division this charming little orchid will now be producing new growths. I have found considerable advantage from placing the plants in slightly warmer conditions than that of the odontoglossum house for a few weeks before the flowers expand. Larger and finer-coloured flowers are then produced, and the plants may be removed again to the cool house as soon as the uowers are fully expanded, where they will be more durable than if allowed to remain in the warmer conditions. There is nothing more cheerful in the orchid houses during the dull winter months than well-flowered plants of Sophronitis grandiflora.

ONCIDIUM CHEIROPHORUM.—Grown suspended near the roof-glass of a cool intermediate house, this species, with its clustered spikes of miniature, brilliant yellow flowers, is most effective and useful for autumn exhibitions and general decoration. The flowers remain a long time in perfection, and, as the species is easily cultivated, it is worthy of every consideration in gardens where a variety of orchid flowers is required in winter. The plants have their flower-scapes in a forward state now, and so must be carefully attended to, to guard against insect pests which readily attack the tender flower-scapes. Repotting may be carried out when the new roots appear, shortly after the plants pass out of flower, but it should not be done more frequently than is absolutely necessary. This species is best grown several plants together in the same pan or basket, and plants never do better than when they have grown into crowded specimens so long as the rooting material is sound and good.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

ROSES IN POTS.—The whole batch of dwarf roses should be examined now, and any repotting necessary must be done at once. In preparing the plants for repotting, carefully remove the soil from about the roots with a pointed stick, using every care to damage the roots as little as possible. A suitable compost will be loam, brick-rubble, old mushroom bed manure, and a sprinkling of crushed bones. Pot firmly, and, when finished, plunge the pots up to the rims in ashes. The plants which do not require repotting must have the drainage made good, and two or three inches of the surface soil removed and fresh compost added. If buying new roses for potting is contemplated, these should be procured and potted at once, using them for the latest batch.

BEGONIA GLOIRE DE LORRAINE.—The earliest batch should now be allowed to flower. Give them plenty of room to develop, and keep them as near to the glass as possible. This begonia is often spoiled by being grown in a stove temperature, as the plants will not remain fresh when placed in the greenhouse or conservatory, neither are they so useful for decorative purposes as when grown under cooler conditions. Now that the flower-buds are expanding, a temperature of 50 or 55 degrees will be ample. Support the flowering shoots with neat ties before moving them to the conservatory. The late batches must be liberally supplied with stimulants.

PLUMBAGO CAPENSIS.—This is a very useful plant for furnishing the conservatory during the summer months. It may be used both for covering a wall or as a pot plant. Plants which have been employed in the flower garden may be potted up, using 6in. or 7in. pots, and kept in a cool house for the winter. They will commence flowering early in the summer, and continue to do so the whole season through. The colour of this variety, which is a pleasing shade of light blue, makes a distinct contrast to other summer-flowering subjects.

CHRYSANTHEMUMS.—From now till the end of the year chrysanthemums will be very much in evidence in the greenhouse and conservatory. To keep them flowering as long as possible strict attention must be paid to watering. Unless they are in close proximity to hot-water pipes once a day will be often enough to examine the plants, but make sure that they receive enough water to soak the ball of soil right through. Watering must be done before noon, and when finished the floors and paths must be mopped dry. Clear water only must be given to plants in flower. Air must be admitted to the structures according to the conditions prevailing outdoors, and, if possible, the top ventilators should be left open a little at all times. Artificial heat must be used sparingly, and during bright sunny weather it should be dispensed with altogether. Examine the large-flowering kinds frequently for damped petals, and, in removing them, be careful not to damage the rest of the flower. The late-flowering varieties may be left outdoors for some time yet, if provision is made for covering them on cold nights. It will pay to disbud such varieties as Madame Oberthur, A. J. Balfour, W. H. Lincoln, Nellie Pockett, François Pilon, White and Yellow Thomson, and others of similar habit.—E. HARRIS, Lockinge Gardens.

HARDY FRUITS.

PEARS.—Old, worn-out trees or useless varieties occupying valuable wall space should be rooted out, and their places filled as quickly as possible with healthy trees of the best and most suitable varieties obtainable. I often wonder why these old encumberers are allowed to remain year after year, producing only a few ill-formed, useless fruits, when, with but little cost and trouble, very fine specimens could be grown. If we are to deal with this work, no time must be lost in removing the old trees and getting the borders thoroughly prepared. The drainage should be perfect, especially in low land or in cold districts. Remove a portion of the old soil, and replace it with moderately rich loam of a lasting character, adding to it a good sprinkling of bones, old brick mortar, and a little well-decayed manure. Upright or oblique cordons planted at two feet apart will give the quickest returns, and these should be planted about three or four inches away from the wall to allow for stem swelling. If cordons are to be used, remove about three feet of the old soil, both in width and depth, and at the bottom of the trench put fully six inches of old brickbats, on which lay turves, grassy side downwards, and then fill up with good soil, as above mentioned, making it rather firm. Trim the damaged ends of the roots, and lay them out as evenly as possible in various directions, and cover up to the depth of six inches.

GOOSEBERRIES.—Prepare land for new plantations of gooseberries; let it be thoroughly trenched, and choose an open position. Gooseberries more than pay for good cultivation, and yet we find these frequently occupying an out-of-the-way spot, unfit for the production of fine large berries. When planting, allow ample room for the development of fine specimen bushes, and select a few of the very best varieties. Young plants raised from cuttings inserted last autumn should be lifted and transplanted to give them a chance of making good planting material by the end of next season. Plant them in lines two feet apart, and 18 inches from plant to plant.—H. MARKHAM, Wrotham Park Gardens.

THE KITCHEN GARDEN.

CAULIFLOWERS.—Where the plants are now "turning in," they should be examined every two or three days, and have the heads thoroughly protected by bending down the inner leaves over the curd; where the heads are just forming draw the leaves together and secure them with a tie of raffia. Those which are fully matured should be lifted and hung head downwards in a cool shed or cellar, where, if syringed every two or three days, they will last a fortnight or so in good condition. To carry on the supply for the next two or three months, plants from the later sowings should be carefully lifted with plenty of roots and soil, and planted in frames or cold pits; a good soaking of water should be afforded when planting is completed. Late sowings of Autumn Mammoth or Autumn Giant are the most suitable for this purpose.

CABBAGE.—All vacancies should be made good and the land be stirred with the draw-hoe. The most forward batch of plants should be earthed up, drawing the soil well up to the leaves. A good batch of all the varieties grown should be planted rather thickly together on a sheltered border, or in a skeleton frame where protection can be afforded if required.

PEAS.—In favoured districts where the soil is of a light character, a sowing of a hardy and early type of pea on a warm, sheltered border will provide early pickings next season. For this purpose, Pilot Improved is most suitable. It is not advisable to sow any of the marrowfats, as they are more liable to rot than the round-seeded type of pea. It is a good plan to place in the drill some well-decomposed leaf-mould on which to sow the seeds.

BRUSSELS SPROUTS.—The early-sown batch of plants has made satisfactory progress, and the sprouts are available for use; to assist their development, have all the decayed and some of the coarser leaves removed from the lower part of the stem to permit light and air to reach the sprouts.

CELERY.—Proceed with the earthing-up of the main crop, but avoid the use of too much soil at a time. The soil should be broken up as finely as possible; secure the leaves firmly together either by tying or holding them with the hands, and make the soil firm round each plant, taking care not to place any higher than the last leaf made. The earthing-up of the latest planting should be delayed as long as possible, as the crop will keep much better in an unblanched condition.

TRENCHING.—When dealing with light soils this work should now be proceeded with, and the earlier it is done the better it will be for future crops.—W. MESSENGER, Woolverstone Park Gardens.

THE NATIONAL CHRYSANTHEMUM SOCIETY'S
GREAT AUTUMN SHOW
OF
CHRYSANTHEMUMS
will be held at the
CRYSTAL PALACE,
on NOVEMBER 5th, 6th, and 7th, 1913.
Write for Schedule (post free) to the Secretary,
Mr. RICHARD A. WITTY,
72, Savernake Road, Gospel Oak, N.W.
Admission to Palace (including Show), 1s.

SCOTTISH HORTICULTURAL ASSOCIATION.

GREAT CHRYSANTHEMUM EXHIBITION
AND BAZAAR,
In Aid of Horticultural Institution Fund,
WAVERLEY MARKET, EDINBURGH,
NOVEMBER 13, 14, and 15.

Prize Lists may be obtained from the Secretary,
A. D. RICHARDSON, 19, Waverley Market,
Edinburgh.
Entries close on November 5th.
Applications for space for Non-competitive Exhibits should be made without delay.

WINDSOR, ETON, AND DISTRICT CHRYSANTHEMUM SHOW.

THE TWENTY-SECOND ANNUAL EXHIBITION
will be held in the
ROYAL ALBERT INSTITUTE, WINDSOR,
FRIDAY, NOVEMBER 7th, 1913.
For schedules and particulars apply
G. E. KEER, Hon. Secretary,
"Meadowlea," Datchet.

THE BOURNEMOUTH HORTICULTURAL SOCIETY.—The Twenty-seventh EXHIBITION of AUTUMN FLOWERS will be held at the WESTOVER RINK, on TUESDAY and WEDNESDAY, October 28th and 29th, 1913. Special engagement of the Band of H.M. Grenadier Guards, by permission of Col. R. Scott-Kerr, M.V.O., D.S.O Conductor: A. Williams, M.V.O., Mus.Doc., Oxon, Second Lieutenant. Will be opened on Tuesday at 2 p.m. by Mrs. H. Page Croft. Schedules to be obtained from the Secretary, W. SHAVE, 118, Ensbury Park Road, Winton, Bournemouth.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Bournemouth Gardeners' Association.

Mr. Crook, of Camberley, a well-known figure in the horticultural world, gave a very interesting and instructive lecture on the subject of "Insect Pests in the Garden" on October 7 before a full attendance of members.

The lecturer said he did not intend to go into details, as time would not permit him to do so. But he wanted the members to think well for themselves after he had given a lead. He said he had never found greenfly on hard wood, but always on young from which the juices could be extracted.

The lecturer dealt on the importance of keeping plants clean, and not allowing them to become infested with insects. This was better than trying to clean a specimen. He instanced Morello cherries and roses as being subjects very soon infested by black and green fly respectively, and said that, if syringing and spraying was begun in good time, carried out once a week, and a weak solution of an approved insecticide used at about a fourth of its normal strength, no trouble would be experienced from pests.

Furthermore, Mr. Crook said, smooth, glossy-leaved plants could be syringed with a stronger solution than rough-surfaced ones, and instanced the pear and apple. Practically all insecticides were more efficacious if warm water was used than cold in the mixing.

A very animated discussion followed the lecture, many members taking part in it. Mr. Crook answered the questions put to him, and was accorded a hearty vote of thanks, as also was Mr. Smith, the chairman.

Dumfries and Galloway Gardeners' Association.

Mr. S. Arnott, Sunnymead, Dumfries, president of the association, gave the opening lecture at the first meeting of this session in the Wesley Halls, Dumfries, on October 11. Mr. W. Hutchinson, Terregles Gardens, a vice-president, occupied the chair. The lecture was on "Alpine Plants," and covered the subject from its various sides, dealing with the natural habits of the alpines and the conditions under which they grew at home, these being contrasted with those under which they were cultivated in this country. The best provision for their cultivation was also considered, the construction of rock, wall, water, bog, and moraine gardens being referred to pretty fully. Propagation and other cultural questions also received consideration, and a short mention was made of several of the leading genera and their value.

A vote of thanks was accorded to the lecturer on the motion of the chairman. The new session promises to be a successful one, and the meeting arranged for two special meetings, on October 30 and November 27, to hear lectures by Mr. A. Hosking, of the Glasgow and West of Scotland College of Agriculture.

Dundee Horticultural Society.

There was a melancholy note in the speech delivered by the President, Mr. W. S. Melville, at the financial meeting of this society on October 9, when, moving the adoption of the various reports, he attributed the loss of £68 on the year's working to the inclement weather which prevailed on the Saturday forenoon of the show. The committee had made a special and determined effort to reduce the expenditure, and had succeeded to the extent of over £100, but the gate money and the membership had been responsible for the deficiency. In eloquent terms he appealed to the wealthy citizens to give "shekels" to help on the labours in what he characterised as "an educative, enjoyable element in the life of their industrial city and district." The record of the society was a good one, and spoke for itself, and were they to let it die out there would be a loud and long hue and cry raised; nevertheless, "without straw they could not make bricks," but they would go hopefully forward to another year. The election of office-bearers resulted in the re-election of all those retiring, and the prize-money for 1914 was fixed at £250. A motion to extend the show to four days was defeated by 27 votes to 17.

Scottish Horticultural Association.

The monthly meeting of this association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on October 7. Mr. David King, the president, was in the chair, and there was an attendance of 100 members.

A paper was read by Mr. David Armstrong, Kirknewton House Gardens, Midlothian, on "The Cultivation of Salvia splendens."

The exhibits were: Collection of collarette dahlias and new early-flowering white Chrysanthemum Artemis (awarded a Certificate of Merit), exhibited by Messrs. Dobbie and Co., Edinburgh, who were also awarded a Cultural Certificate for the dahlias; new early-flowering yellow Chrysanthemum Golden Diana (awarded a Certificate of Merit) and Chrysanthemum Framfield Early White, exhibited by Messrs. Todd and Co., Edinburgh; early-flowering chrysanthemums, exhibited by Mr. John Downie, Edinburgh; Ficus sp., exhibited by the President; Canadian-grown peaches, exhibited by Messrs. James Grieve and Sons, Edinburgh; potato Irish Gem, exhibited by Mr. Wm. E. Sands, Hillsborough, Co. Down; potatoes Dobbies' Prolific, The Chapman, and The Admiral, exhibited by Miss Burton, Polton, who was awarded a Cultural Certificate; runner beans Webbs' Golden, Webbs' White-seeded, and Webbs' Exhibition, exhibited by Mr. Walter Y. Staward, Aston Gardens, Oswestry, Salop; and Cunynghame's Frost Predictor, exhibited by Messrs. Stewart and Co., Edinburgh.

At the meeting on November 4 a lecture will be given by Dr. W. G. Smith, Edinburgh and East of Scotland College of Agriculture, on "The Influence of Drought on Plant Form" (with lantern illustrations).

Cardiff Gardeners' Association.

The fortnightly meetings of the above society recommenced at the Queen's Hotel, St. Mary's Street, Cardiff, on the 7th inst. The President, J. J. Neale, Esq., Penarth, presided over a good attendance, and four new members were elected.

The lecturer was Mr. A. Cobb, The Gardens, Duffryn, St. Nicholas, and his subject, "Dahlias for Garden Decoration," was illustrated by lantern slides, several of which were from recent colour photographs. The dahlia was first introduced in 1789 from Spain by the Marchioness of Bute, and now Reginald Cory, Esq., Mr. Cobb's enthusiastic employer, has awakened a great interest in the flower by growing a wonderful collection of varieties. Mr. Cobb, in his interesting lecture, spoke of the fine qualities of the various sections, and singled out the paeony-flowered as the most attractive for forming bold masses in the mixed herbaceous borders. The star varieties and Parisian singles were, he said, most suitable for table decoration, etc. The discussion which followed evidenced the lasting qualities of the collarette section both as cut blooms and during wet weather. It was also pointed out that a late batch of cuttings, grown in small pots to produce planting tubers for the following year, were best for small gardens.

Croydon Gardeners' Society.

On Tuesday last, at this society's rooms, Sunflower Temperance Hotel, George Street, the members attended in force to hear a lecture given by Mr. E. Scaplehorn, Lindfield. Mr. Scaplehorn has been a grower and exhibitor of hardy flowers for many years, and his reputation as an expert is widely known. Mr. Scaplehorn said that popularity necessarily brings improvements, and the work of the hybridist, as well as the plant collector, had created wonders in this department. There is such a diversity of colour and an extension of flowering periods that one may arrange a border into colour schemes which may possess one tone of colour such as a blue border, a red, a white, or almost any hue one chooses; and amongst the plants there are sufficient varieties to provide bloom during all the year.

The lecturer favoured a mixed border, his reason being that it is more attractive and contains more interest to the general observer. If there is one chief characteristic about the hardy flower border it is that it may be situated at any aspect, and there are plenty of plants to provide a wealth of bloom. The best site, however, is south or south-east, backed by a wall. Upon the wall can be trained some of the taller climbing varieties, and slanting to the front there are plants of all heights to fill the border. Another position is that in front of a shrubbery when taller-growing trees require colour to brighten up the scene.

For most of the subjects a well-trenched and well-drained soil is required. When trenching a liberal dressing of well-decayed manure should be incorporated, and this is best done in the early autumn. A surface dressing of sulphate of potash, in the proportion of ¾oz. to the square yard, will suit the plants, and also conserve moisture in the summer months. When the border, which should be as wide as possible, has been well made and planted, only occasional dressings

of rotted manure slightly forked in will be necessary to keep it in condition.

With the aid of the society's electric lantern Mr. Scaplehorn showed views illustrating well-made borders, etc. As each picture was shown the lecturer advised the best methods of propagation, and the most suitable soils for the plants. To support some of the taller-growing kinds he recommended using stakes and the bushy pea boughs.

Exhibits brought by the members included dishes of apples staged by Messrs. E. Mann, O. Jeal, and A. J. Holcombe. Mr. Mann also contributed a few vegetables; and Mr. G. Scrivens had a vase each of Salvia Zurich, Michaelmas daisies, and pompon chrysanthemums. Mr. F. W. Moore brought an interesting exhibit of the Cape gooseberries.

Bristol Gardeners' Association.

The opening meeting of the winter session of this association was held at St. John's Parish Rooms on Thursday, October 9, Dr. Shingleton Smith presiding. Mr. E. T. Parker read a most interesting paper on "The Dutch Bulb Farms, and Gardening Operations in Holland," which was much enjoyed by a large audience. Mr. Parker gave a detailed description of the methods of propagation, planting, and storing of the various kinds of bulbs, and referred to the work of a Dutch bulb farmer. A good discussion followed, at the close of which votes of thanks were accorded to Mr. Parker, and Dr. Shingleton Smith. The prizes for the evening, kindly given by Mr. Garnish, for an effective vase of chrysanthemums, own foliage, were won by Mr. Bird and Mr. Baston in the order of their names.

Wimborne Gardeners' Association.

On Monday, October 6, Mr. Geo. Garner, of Bournemouth, gave a lecture on "Some Salient Points in the Forcing of Bulbs and Plants" before a good attendance of the members of the above association. Mr. J. Stevenson, of Wimborne, occupied the chair.

The lecturer, having referred to the fact that in these times flowers for dwelling-house decoration, as well as for furnishing greenhouses and conservatories, were in more demand than was the case a generation ago, dealt with some of the main points essential to successful cultivation.

He recommended clean sand for burying bulbs in pots and boxes, and warned any inexperienced growers against using coal ashes fresh from the furnaces; ashes that had been exposed for six months to the weather might be used. He also recommended watering, and especially the feeding, of bulbs in pots from saucers, allowing the liquid to remain in the latter for twelve hours and then emptying away any surplus. This form of feeding might be done three times each week after the flower stems were well advanced. He said it was fatal to the general welfare of tulips to allow the soil to get very dry after growth had commenced.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

Having referred to the forcing of lilac and other kinds of shrubs, the lecturer answered a number of questions. The members, led by Mr. Stevenson, took part in a very good discussion. Some excellent vegetables, in collections, were staged.

AURICULAS.

As a keen auricula grower, I was very pleased to see an article on these plants in your issue of the 4th inst. Before reading it I glanced at the subscriber's name, and hoped for something really good from such a well-known expert as Mr. Bentley. As I thoroughly appreciate this gentleman's success as a grower and exhibitor, I am sure he will take in good part my gentle "dressing down" for not being right up to date in important matters touching the cult.

He, naturally enough, regrets the lack of such men as Simonite, Douglas, and Horner who have passed from their activities, and sighs at the apparent impossibility of making further progress without the help of such giants. Does Mr. Bentley know a green edge of the name of Wm. Smith? If not, I would like to whisper in his ear that it is the finest that has yet seen light, and it well earned a premier award last spring at Vincent Square. This was raised, not by any of the wonderful growers of 20 or 30 years ago, but by the son of the late Mr. James Douglas at Bookham. Wm. Smith was, by common consent, and in comparison with Mrs. Henwood, Shirley Hibberd, and Orient (about 80 specimens of which were staged alongside), judged to be the finest green-edged auricula of the present day. Another triumph scored by young Mr. Douglas last April was premier of the whole show with Victor, a dark self of perfect proportions, which must be recognised by Mr. Bentley as a distinct advance.

The story is the same as regards the white-edged section; Guy Cranfield, Eucharis, and Loveliness, when better known, will make Heatherbell, Frank, and even Acme look out of date. I don't like saying so of the last-named, but there is no use ignoring the fact that Acme is not so good as it used to be. There is also a new grey-edge raised by a collier in Northumberland, said to be as good as Geo. Lightbody, but it is growing very, very slowly, and will not increase as its raiser hoped it would.

Some of the varieties mentioned by Mr. Bentley are out of date. Who would ever put on the show bench such auriculas as Robert Trail, Beauty, and Ruby? Even Olympus, Mrs. Potts, and Conservative have to be in exceptional fettle to justify their inclusion.

Silverwood, Belmont. J. L. Gibson.

Plums.—Any trees that have made too much unfruitful wood should be lifted and root-pruned some time after this date. See that the roots are thoroughly moistened before starting to dig around them. Take out a trench quite two feet wide at a distance of four feet away from the stem; get well down, and work the soil carefully from amongst the roots, avoiding damage as far as possible; when within two feet of the stems, undermine and sever every root that is travelling downwards, for if one or two of these are missed the whole of the work may prove useless. Trim the tips of all damaged roots, and relay at various depths. Work plenty of fine soil among the young fibrous roots, and if the soil is moderately dry give a good watring, and mulch afterwards with long strawy manure. Should the weather prove dry and warm, a few syringings overhead will help to keep the leaves and wood plump. Keep a good stock of useful trees trained in readiness to take the place of those which give out, as valuable wall space can be then quickly filled, and much time is saved. Good useful varieties are Coe's Golden Drop, Comte d'Althan's Gage, Green Gage, Early Transparent, Jefferson, Kirk's, Oullin's Gage, Washington, Czar, Monarch, Victoria, Sultan, Gisborne's, Pond's Seedling, Cox's Emperor, and Prince of Wales.—H. Markham.

THE WINTER AND CODLING MOTHS.

The following is the text of the lecture given by R. A. Harper Gray, Esq., M.A., B.Sc., Adviser in Agricultural Zoology, Armstrong College, Newcastle-upon-Tyne, at the Kendal Fruit Congress:

My reason for choosing these pests is partly because they are so common in our orchards and therefore likely to interest a Congress audience, and partly because there are points in the life-history of each which go to show very clearly the importance to the horticulturist of a knowledge of economic entomology in devising means of preventing or of minimising the injuries associated with the presence of such pests.

I.—The Winter Moth (Cheimatobia brumata).

The moth commonly called the Winter Moth or Evesham Moth, is small in size, and only in the males do we find fully-developed wings. The front wings are greyish-brown to brown in colour, with transverse darker wavy lines, while the hind wings are uniformly paler. These males may be seen flying rather lazily in orchards and gardens during the latter months of the year, and, in favourable weather, in January and even in February in some parts of the country. The females, on the other hand, are quite unlike the males, inasmuch as they possess only vestiges of wings—indeed, so abortive are they that they are useless for the purposes of flight.

Both these—male and female—have issued from the chrysalids, or pupæ, which have been lying in the ground some little way below the surface. The female moths, on emerging from the ground, proceed to make their way up the stems of the trees, and it is on the way up that they appear to be fertilised by the males. At any rate, on reaching the smaller branches of the trees, they begin laying their eggs. These small eggs have a light greenish-yellow colour, which after a short time, becomes reddish, and they have a thick sculptured shell. They are laid in tiny groups, round the base of the buds, or on pruned surfaces, and in the small crevices on the branches and twigs. From these eggs come the caterpillars that are so destructive. The time elapsing between the laying of the eggs and the appearance of these caterpillars or "loopers," varies in different years and in different places, most probably owing to climatic conditions, but the eggs usually hatch out some little time before the buds burst, and the caterpillars begin at once their work of destruction.

During the years 1911 and 1912, I made a special study of the habits of the caterpillars of the Winter Moth in the North, by keeping a close watch on them, not only in the laboratory, but also in the open. I think, therefore, that some of the more general of these observations should be of interest to the Congress, not only because they will serve to show the habits of the caterpillars, but also because they refer particularly to our Northern Counties.

In 1912, in which year the Winter Moth larvæ were very prevalent, they were first reported to me as having been seen on April 22, and they were then one-quarter of an inch in length. A week later they were doing much damage on apples, pears, plums, and gooseberries in Northumberland. On May 7 I found the leaves on many trees much destroyed. There were large holes in the leaves, and they were also eaten round the edges. Many leaves were almost entirely destroyed, practically only the mid-rib remaining, while some of the leaves were connected by fine silk threads, evidently made by the caterpillars travelling from one leaf to another. The blossoms showed signs of attack, and the petals were falling off.

Two days later (May 13) some of the larvæ took up a position between the lower side of one leaf and the upper side of another, living well sheltered by the silken threads

surrounding them. On this date I found an interesting case of a blossom from which all the petals had fallen, leaving only the calyx through which a larva was boring into the fruitlet. And they proceed even farther, for in places where gooseberries are grown near apple trees, or in orchards under apple trees, I have found that they readily attack the gooseberries, and this year they have been reported to me as having been attacking black currants.

I also find, in my records for 1912, that they were attacking many trees, viz., the horse chestnut, lime, sycamore, elm, hawthorn. As a matter of fact, they are known to attack many other trees outside our orchards, but I mention the above as having come particularly under my notice in 1912; they are sufficient to give us an idea of the varied nature of the food plants acceptable to the larvæ of the Winter Moth.

By the end of June, in the North, the caterpillars are mature, and proceed to the ground, where they hide under the earth, usually to a depth of two or three inches. Last year I reared a male and female Winter Moth from pupæ which were just under the surface of the soil. This, however, was under the somewhat artificial conditions of a breeding cage in the laboratory, and it is probable that, in the open, the larvæ usually go farther down, as already mentioned.

When in the soil, they spin round themselves a silken cocoon, which will be found covered with particles of earth. Soon afterwards the larva inside changes into a brown pupa, and it is from this pupa that the adult moth emerges at the latter part of the year (October to January).

II.—The Codlin Moth (Carpocapsa pomonella).

The Codling Moth is small in size, and may be easily identified by examining the wings when spread out. The front wings are grey in colour, with an oval patch of a dark golden hue at the tip of each, while the hind wings are of a darker grey, with a slightly golden sheen. During the daytime, however, the moths may be easily passed by unnoticed, as they cling to the undersides of the leaves, or to the bark of the trees with their wings folded in a roof-like manner.

The moths may be seen flying in our orchards at the time when the apple blossom is falling, and they are most active towards evening, at which time the female moths proceed to lay their eggs singly on the apples that are just forming. These eggs, when newly placed on the side of the fruitlets, are white, shining bodies, scale-like, and roughly oval in shape.

In a week or ten days, a tiny caterpillar hatches from the eggs, which, as a rule, eats through the "eye" of the apple, and makes a tunnel to the core. After feeding on the seeds and the surrounding parts till it is full grown, it forms another tunnel from the centre to the rind, and thus escapes. By this time, however, the vitality of the apple may be so destroyed that it falls to the ground, whence the caterpillar proceeds to the nearest stem in order to spin its silken cocoon.

If, however, the apple has not fallen to the ground, the caterpillar may make its way down the branches and stem until it finds a suitable crevice in the bark where it may pupate, or it may let itself down to the ground by means of a silken thread, in which case it generally reascends the tree to spin its cocoon.

The caterpillars remain thus sheltered till spring, when they change into yellowish-brown pupæ, from which the moth emerges about the end of May or the beginning of June.

Application of the Life Histories to Methods of Prevention and Remedy.

Having treated of the essential points in the life histories of these two pests, we are in a position to appreciate more fully the reasons for adopting the methods recommended for meeting the attacks of each.

I.—The Winter Moth. Grease-banding as a Preventive.

The habits, for example, of the Winter Moth clearly suggest a simple means of prevention, viz., the preventing of the wingless females from getting up the trunks of the trees in autumn and winter. It is this peculiarity in the structure of the female Winter Moth (the absence of functional wings) that has suggested the idea of grease-banding. Bands, six or seven inches in width, and made of grease-proof paper, are tied firmly round the trunk of the tree, and then covered with a sticky grease.

There are several "makes" of this sticky grease on the market, which are claimed to possess a more or less permanent stickiness. It may be well to note, however, that whatever grease is used it is advantageous to "comb" the grease with the fingers, so that horizontal furrows and ridges are formed on the band.

By so doing, the grower will find that the grease will retain its "stickiness" for a longer period than if left on the paper as a uniformly thin layer.

The position of the bands on the trunks requires consideration. Some growers place them high up—four or five feet from the ground—while others prefer to have them only a foot or so from the ground. The objection brought forward to having the bands placed high up is that many eggs are found to be laid in the crevices of the bark below the band, and by the time the caterpillars from these begin to ascend, the grease has lost its "tacky" qualities, so that they can crawl over it and reach the boughs. It would seem, therefore, that if the bands were placed lower down the number of eggs likely to be laid would be small, and therefore fewer caterpillars would succeed in getting over the grease-band in the event of its having become dry enough for them to do so. One objection to the low band is that, where the ground in the orchard is cultivated, the band may become covered with mud or dust, and, again, it is just possible that the males may carry the females safely over a low band.

On the whole, I consider the placing of the bands three to five feet from the ground preferable to placing them so low down—providing that the grower makes sure that the bands are kept in good working order.

The bands should, in the North, be on the trees by the middle of October, and I would here point out that one application of grease is not enough. As I have said, it is the duty of the grower to see that the grease is in proper working order, and whenever it shows signs of dying, a second application should be put on, probably in December, and again in March, to prevent any caterpillars that may have hatched out below the band from ascending, and at the same time to serve for catching the March moth.

Damage from Winter Moth larvæ has not been so marked this season as compared with 1912, in Northumberland at least, but Mr. Withers, who has ably helped me in adding to or confirming the observations I have made on the habits of this pest, has reported that trees which were grease-banded in autumn certainly do show less damage than unbanded trees growing alongside. Careful records were kept and the bands caught a large number of apterous moths, so that it was only to be expected that not so much damage would result.

On October 4, 1912, grease-bands were put on four trees that had been specially badly damaged that season, and marked for the experiment—two Potts' Seedlings and two Lord Grosvenors.

On October 22 the bands were sticky and effective, and much covered with winged insects, but no Winter Moths; but when observations were made on November 16, one tree had 15 females and many males, the next 9 females and many males, the next 24 females and a few males, while the fourth had 19 females and a very few males adhering to the band. On December 7, only four females and a few males were caught. On February 1, the bands were still kept in working order, but no females had been entrapped since December 7.

The number of females caught, as given above (71 from the four trees) is exceedingly small compared with the numbers given for observations in other parts of the country in other years, but when one considers that one female may lay from 150 to 200 eggs or more, one can understand how effective grease-banding is in preserving our orchards from the ravages of Winter Moth caterpillars.

Spraying as a Remedy.

When the caterpillars are on the twigs, which is sure to happen where grease-banding has not been carried out, or has been carelessly applied, they can be got rid of by spraying the trees with arsenical washes from a fine jet. Owing to the scorching effect of Paris Green on the leaves, arsenate of lead, bought in paste form, is now recommended as being the better spray to use as a remedy against the Winter Moth larvæ. Where grease-banding is not carried out, spraying should begin as soon as the leaves appear in order that the caterpillars may be destroyed before they have done any damage, and again within 10 days after the blossom has fallen. In this way the Codling Moth, March Moth, etc., are also coped with.

II.—The Codling Moth.

With regard to the habits of the Codling Moth, there are two points to which I wish to draw attention. One of these is that on leaving the apple on the tree large numbers of full-grown caterpillars proceed to crawl down the branches to seek shelter in the rough parts of the bark on the stem, or they may get to the ground in the manner described and reascend.

This habit has led to the adoption of a method of prevention which has been made compulsory by law in California and Tasmania, viz., to place firmly round the trunks, close to the ground, bands of hay, clean sacking, etc. In order to further encourage the caterpillars to enter these traps, the tree-trunks should be kept free from rough bark. The bands are examined periodically during summer and autumn, and the caterpillars found sheltering in the bands are destroyed.

The second point is that many apples containing the caterpillars fall to the ground, the caterpillars escape, and proceed to pupate—usually on the tree trunks. These "windfalls," therefore, should be cleared away as quickly as possible.

Here, again, spraying with arsenical sprays is to be recommended as a remedy when the eggs are on the fruitlets, or against any caterpillars that have remained above the band. This spraying should take place while the calyx of the apple is still open, that is, within a week after the falling of the blossom. The reason for this will be seen by referring back to what has been said of the life-history of this moth. Suffice it to say that the wash will thus be retained by the calyx, so that the first "bite" of the caterpillar will contain the poison which will kill it.

FORTHCOMING ENGAGEMENTS

NEXT WEEK.

MONDAY, October 20.—Annual General Meeting of the National Sweet Pea Society, Hotel Windsor, Victoria Street, Westminster, at 2.30 p.m.; dinner at 6 p.m.; Conference at 7 p.m., when Mr. J. S. Bruaton will lecture on "The Sweet Pea Industry."

TUESDAY, October 21.—Royal Horticultural Society; Committees meet at 12 o'clock; Lecture at 3 p.m. on "The Evolution of Plants, and the Directivity of Life shown by the Reproductive Organs," by Rev. Prof. G. Henslow, V.M.H.; Scientific Committee at 4 o'clock.

WEDNESDAY, October 22.—Hereford Fruit and Chrysanthemum Show; two days.

CATALOGUES RECEIVED.

A. J. KEELING AND SONS, BRADFORD.—An interesting general list of orchids, illustrated, with a special offer of unflowered seedlings.

JOHN JEFFERIES AND SON, LIM., CIRENCESTER.—A useful list of roses, fruit trees, ornamental trees and shrubs, and herbaceous plants.

AUCTION SALE AT COOMBE WOOD NURSERY.

An event of unusual interest and importance in the horticultural world was the sale of nursery stock on the Coombe Wood Nurseries which opened on Monday, October 13, and continued until Friday, October 17. The interest was twofold, first on account of the wonderful variety and high quality of the trees and shrubs offered for sale, and secondly by reason of the fact that the event marked a further step towards the departure of the illustrious firm of James Veitch and Sons from the field of British horticulture. It has become common knowledge that Sir Harry Veitch intends to retire from business, and that the whole business of the firm, whose name is a household word throughout the realm of horticulture, will ere long terminate its operations. The seed business has already passed into the hands of Messrs. Sutton and Sons. The collection of orchids and the orchid houses has been sold, and the week just ending has witnessed the sale by auction of a large portion of the stock of trees and shrubs, including many choice Chinese plants which have been recently introduced to commerce by the firm. Messrs. Protheroe and Morris have during their career conducted many important sales of nursery stock, but even they must have felt that this week's sale was by way of being unique. As Mr. Slade remarked at the opening, the name of Veitch has long been held in highest esteem throughout the horticultural world. Not only has the firm been renowned for the quality of the plants grown, but they have been raisers and introducers of probably more plants of sterling merit than any other firm. In the course of an appropriate and well-received speech, Mr. Slade referred to the personal qualities and business abilities of Sir Harry Veitch, whose courtesy, benevolence, and knowledge had won him the respect and esteem of all who had come in contact with him, and he expressed the wish that every horticulturist will heartily endorse, that Sir Harry will live to enjoy many years of well-earned peace and happiness after he finally severs himself from the sphere of commercial horticulture, to which he has been an ornament and a benefactor. Sir Harry Veitch, in a few well-chosen words, expressed his appreciation of the kind remarks that had been made, and also thanked the company for their presence at the sale. One might have expected a larger gathering, but it soon became evident that those who attended were there for business, and some brisk bidding was made.

We noticed among the buyers General Sir Alfred Paget, the Hon. Lady Ronald Greville, Mr. W. Watson (Kew), Mr. Whitton (Glasgow), Mr. D. Thomson (Edinburgh), Mr. P. Weathers (Manchester), Mr. Boyle (Ireland), and Messrs. Hutton, Davidson, Fletcher, Matthews, Kelly, Paul, and Jackman. The lots were arranged in convenient numbers, and the trees and shrubs, being for the most part useful kinds of convenient size for removal, very fair prices were realised without difficulty. The larger material, such as specimen hollies, golden yews, cedars, etc., went cheaply, but smaller trees, flowering shrubs, cut-leaved acers, magnolias, etc., in many instances realised fully catalogue prices.

One particular lot that ran up to a remarkably good figure was a row of nine plants of Berberis Wilsonæ, which realised 63s. Lots of various ornamental shrubs, numbering about 25 plants, made up to £4 and £4 5s., and climbers in pots sold at from 9s. to 15s. per dozen. There were some fine stools of lilacs, spiræas, philadelphus, etc., with rooted layers attached, and these formed the chief attraction to the trade; whilst the superintendents of public parks were keen on the well-furnished specimens that would produce immediate effect. Altogether the auctioneers may be complimented on the manner in which this great sale was handled, and Messrs. Veitch may be congratulated upon having brought forward a remarkable stock of most useful plants and trees.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of The Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of The Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

BORAX AS MANURE.—A. M. B., Wavertree: I have a quantity of borax, and am told that it will make a good manure. Will you kindly tell me if this is so, and how it should be used?—Borax is of very little value as manure, and would be of much greater service if used as a cleansing medium. It is used in glass-making, glazing, and in medicine, as well as in domestic washing as a substitute for or economiser of soap. If you desire to dispose of your borax in the garden, spread it thinly, say, 2oz. to the square yard, in spring, over borders occupied by fruit trees, or among quick-growing crops in the kitchen garden.

COTONEASTERS.—G. S., Bournemouth: Will you please tell me which of the cotoneasters are evergreen, and which deciduous?—Among the better-known cotoneasters the evergreen kinds are C. buxifolia, C. microphylla, C. pannosa, C. rotundifolia, and C. thymifolia; and the deciduous sorts are C. acuminita, C. affinis, C. bacillaris, C. frigida (almost evergreen), C. horizontalis, C. integerrima, C. laxifolia, C. multiflora, C. nummularia, C. Simonsi, and C. tomentosa.

VARIETIES OF SOLOMON'S SEAL.—C. M. S., Bridgwater: I shall be glad if you will inform me, through your columns, whether there are any varieties of Solomon's seal. I grow this plant very successfully, both in the open and in pots, and if there are varietal forms I should like to obtain them; so any help you can afford will be appreciated.—There are several varietal forms of Polygonatum multiflorum, and the chief of these are the variegated variety P. m. striatum; P. m. roseum, from the Altai Mountains, with rosy flowers; P. m. flore pleno, with double flowers; P. m. bracteatum, a late variety with strongly-developed bracts; and P. m. Broteri, a large-flowered or "gigantea" form.

BLACKENED LEAVES OF CHRYSANTHEMUMS.—R. B., Bickley: Please tell me what is the matter with the chrysanthemums I send you. In many cases the leaves have become blackened like those sent, and this lowers the vigour of the plants considerably. Any help you can give will be much appreciated.—An insect has pierced the epidermis of the leaves, and the punctures are readily discernible; what the insect is we cannot say, but probably Lygus pratensis, a sort of bug that is a fairly common enemy to the chrysanthemum. The pest pierces the epidermis of the leaf and sucks out the sap, and so the leaves blacken and decay. Through the punctures it is a quite simple matter for a fungus to enter the leaves and complete the work of destruction, but the insect attack is the beginning of the trouble, and spraying regularly with a paraffin emulsion would render the foliage distasteful and do a great deal to ward off attacks.

TURF FOR A GRAVE.—Anemone, Ewell: I should be pleased if you could help me in regard to obtaining some nice green turf on a grave. The grave was turfed about eighteen months ago, but I am afraid the turf was of very poor quality. I have tried to improve it by the use of fertilisers, by beating, by sowing seeds, and by keeping the grass cut regularly once a week, but the turf is very weedy, and a tiny creeping weed is now becoming quite plentiful.—If you could protect the surface from birds it would be an excellent plan to sow the grave-top with lawn grass seeds in spring; but as this will, in all probability, be out of the question, the next best thing will be to obtain some first-rate turf from someone who has to do with tennis lawns, golf links, or cricket ground, or you might write to Mr. Jas. Macdonald, Harpenden, who makes a speciality of raising grass on a prepared material all ready for laying down.

PIG NUTS OR EARTH NUTS.—E. M. S., Belfast: You will very greatly oblige several of your readers in the North of Ireland by stating, in your columns, the name of a plant, fairly common in the northern parts of the Sister Isle, which goes by the name of pig nut. The root is more or less tuberous, and when roasted it is said to be very much like a chestnut.—The plant is Conopodium denudatum, an umbellifer, about 2ft. high, with umbels of tiny white flowers. It is of rather wide distribution, and found in the British Isles from Shetland to the Channel Isles. The brownish root-stock is about the size of a chestnut. St. Anthony's Nut is also a title sometimes given to the pig nut, probably because St. Anthony was the patron saint of pigs.

YARROW IN A BOWLING GREEN.—D. R. Y., Ayr: We have a bowling green which is badly infested with what I call "yarrow"; it is, I think, an achillea, and is growing very strong. Can you suggest any remedy for this weed, one that will not damage the grass?—If the yarrow has spread very much and killed the grass, it must be cut out, and the bare places must be re-turfed; but if it is as yet a minor evil, the application of lawn sand, followed later by a suitable top-dressing, will no doubt remove the trouble.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

R. G. W., Kettering.—1, Polygonum Baldschuanicum; 2, Coronilla varia.

T. A., Harrow.—1, Oncidium pubes; 2, a quite good form of Cattleya Hardyana.

H. H., Tenterden.—1, Physalis Alkekengi; 2, Berberis Thunbergi; 3, B. stenophylla.

W. K. R., Winchester.—1, Libonia floribunda; 2, Aglaonema costata; 3, Viola cornuta; 4, not recognised.

A. J. F., Horsham.—1, Cedrus atlantica glauca; 2, Cotoneaster horizontalis; 3, Cimicifuga simplex; 4, Rhus cotinus.

P. J., Okehampton.—1, Gerbera Jamesoni; 2, Rudbeckia speciosa (this used to be commonly known in gardens as R. Newmani); 3, Arbutus Unedo.

F. B. C., Lichfield.—1, Ruscus racemosus; 2, Pteris umbrosa; 3, Physianthus albens; 4, probably Mackaya bella, send when in flower; 5, Todea superba; 6, Hedera helix dentata.

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, Gardeners' Magazine, as advised in the notice at the head of "Answers to Correspondents."

B. C. K., Haverford.—1, Mere de Menage; 2, Warner's King.

E. B. C., Limerick.—1, Lane's Prince Albert; 2, King of the Pippins; 3, Col. Vaughan.

C. T., Ilfracombe.—1, Peasgood's Nonsuch; 2, Bismarck; 3, Court Pendu Plat; 4, Adam's Pearmain.

W. B., Calcot.—1, not recognised, send again later; 2, Cornish Aromatic; 3, Hollandbury; 4, Fearn's Pippin.

G. R. S., Alnwick.—The fruits sent were all very small, and did not appear to be in good character. Nos. 3 and 5 we do not recognise, but we believe the others are: 1, Gravenstein; 2, Dumelow's Seedling; 4, Yellow Ingestrie; and 6, Keswick Codlin.

VOL. LVI.—No. 3,130. SATURDAY, OCTOBER 25, 1913.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Essentials of Success in Rose Culture.

The several contributions to our present issue on the all-important question of rose cultivation cover so large a proportion of the area of the rose garden that those who are careful to make themselves fully acquainted with the advice given should be able to achieve a high degree of success in the planting and management of those parts of their gardens devoted to roses. It will be seen from the information contained in the contributions on roses that the chief essentials to success in the cultivation of these flowers are a thorough preparation of the soil, the selection of varieties suitable for the purpose desired, careful planting, and close attention subsequent to the latter operation, necessary to maintain the plants in a robust state of health. This attention will involve careful pruning, and in making such provisions as will enable the plants to obtain the necessary supplies of plant food and moisture. To do these things, important as they are, will not involve a heavy outlay or impose a serious tax upon the time of the owners of gardens, but they will, in some few cases, require an expenditure rather greater than is occasionally thought necessary, and will necessitate care and watchfulness, and call for rather more energy during the more busy periods than some may be disposed to give. Thorough soil preparation may well be described as the foundation of success, because so close is the association of the roots and branches that unless the former are provided with a medium in which they can readily extend, and obtain liberal supplies of plant food, the growth will be weak and the development of the flowers unsatisfactory. It may not, in many cases, be possible to obtain good turfy loam, which is so strongly recommended, and is unquestionably an important factor in the achievement of a high degree of success, but the inability to obtain supplies should not be regarded, as is now and again done, as a barrier to deep cultivation. The soil must be broken up to a depth of two or three feet, and when this cannot be properly done without bringing the unfavourable subsoil to the surface, remove a portion and replace with ordinary garden soil, should nothing better be available. A few barrowfuls of such soil from one of the quarters of the kitchen garden will greatly improve the soil conditions, and materially assist the plants in their development. Let it not be forgotten that leaf-mould and decayed vegetable refuse, which are both plentiful in not a few gardens, may be utilised with great advantage, especially where the soil is naturally light. Leaves and other vegetable matter in an advanced state of decay contain plant food in appreciable proportions, but their greatest value is the aid they render in helping to conserve the moisture so essential to the full development of the roses. The selection of varieties that are suited to the purposes for which they are required is most essential, and it is satisfactory to have evidence that its importance is being recognised; but the recognition is proceeding so slowly that an acceleration is most desirable. We are anxious to see reared aloft in gardens standards with buxom heads bearing, in the season, a plenitude of flowers of high quality, instead of the poor, weakly objects that are seen in so many gardens. There is no difficulty in having the garden embellished with the finest examples of these, provided planters will limit their selections to varieties that have a strong constitution, instead of selecting, without regard to the constitutional vigour of varieties. The range in colour of one is not greater than the other, while there is no great difference in the variation in colour they afford. In the selection of dwarf varieties also considerable care is necessary, more especially when they are to be grown in beds on the lawn. Whether the beds are to be devoted to one variety only, or to contain several, the whole of the plants should be uniform in growth, the effect being anything but pleasing when the strong growers are associated with those of a quite dwarf habit. It is important also in this case that the varieties be selected with due regard to harmony of colour. A point of primary importance in the subsequent management of the rose garden is the maintenance of the fertility of the soil by judicious cultivation. Owners of gardens should disabuse their minds of the idea, which is all too prevalent, that when once roses are planted they are able to take care of themselves for an indefinite period. This is not so, as may frequently be seen even in gardens wherein roses are grown with some degree of success. From three to five years will be a sufficient length of time for the beds to remain undisturbed, the exact period being determined by the condition of the plants. When these show an indication of a decrease in vigour they may, with advantage, be lifted, and the bed remade, previous to their being replanted. The substitution of new compost for a portion of the old soil will be an advantage, but if nothing more can be done than trenching the soil and incorporating a moderate quantity of manure therewith, the roses will benefit greatly. In some cases the beds will have received such liberal additions of manure annually that a dressing of slaked lime will be more beneficial in its effects than would an application of some

MR. W. BATCHELOR.

manurial agent. Especially will the lime be useful for the purpose of sweetening the soil when liquid manure has been used freely. A matter of considerable practical importance that is referred to by one of our contributors is the necessity for devoting special attention to the provision of an ample water supply for roses trained to pillars. What is said with reference to these applies with still greater force to roses clothing pergolas and trained to walls. In such positions the moisture that reaches the roots is much less than in beds and borders, and unless this deficiency is made good, the plants suffer, and fail to make a satisfactory growth. Roses are moisture lovers, and when growing where there is a shortage they should be assisted with liberal supplies at intervals, the first being given when new growth commences. If a practice was made of maintaining the soil in a moist state about the roots of climbing roses we should hear fewer complaints of the havoc made by aphis, or of the failure to obtain ample leafage and flowers.

Mr. W. Batchelor.—It is with very great pleasure we present our readers with a portrait of Mr. W. Batchelor, who for eleven years has been head gardener and estate steward to B. Wentworth Vernon, Esq., at Stoke Bruern Park, Towcester. Altogether Mr. Batchelor has been in the service of Mr. and Mrs. Wentworth Vernon for five-and-twenty years, as he was with them at Harefield, Uxbridge, previously. Mr. Batchelor is not an exhibitor, but he is a splendid cultivator, and probably in no garden in the kingdom is there such a profusion of bloom during the summer season as at Stoke Bruern Park. Mr. and Mrs. B. Wentworth Vernon love their beautiful garden, and are always pleased when visitors come to enjoy its beauty. The garden is practically always open to the public, and on Sunday evenings many people take advantage of the owners' kindness and enjoy a few hours in this garden fair. Roses are a conspicuous feature at Stoke Bruern Park, and there are over three hundred ramblers on poles and arches in the kitchen garden alone, and all the borders in this part of the garden are edged with flowers. To keep such a garden in the pink of condition is no light task, but Mr. Batchelor manages it, to the great satisfaction of his employers and the delight of the people resident in the district. He has little time for raising new flowers, but in 1895 he gained an Award of Merit from the Royal Horticultural Society for the decorative dahlia Willie Batchelor, and on October 7 he gained a similar award for Tithonia speciosa (Helianthus speciosus), a showy annual with orange-vermilion flowers. Mr. Batchelor tell us this is very showy in the garden, but it must be sown early, in warmth, to be of real value. As evidence of the regard in which he is held, Mr. Batchelor was presented with a solid silver tea service by Mr. and Mrs. Wentworth Vernon on the completion of twenty-one year's service, and the occasion of his silver wedding, the dates coinciding.

"Gardeners' Magazine" Fruit Number.—We have once more entered on the season for planting fruit trees, and to enable us to assist our readers in carrying out the various operations connected therewith we shall devote our next issue (November 1) chiefly to fruits. The contents will include articles on "Soil Preparation for Fruit Trees," "Autumn-fruiting Raspberries," "Cordon Apple Trees." "Best Twelve Fruits for Exhibition," "The Black Currant Mite," "Some of the Newer Fruits," "Promoting the Fertility of Fruit Trees," and "Cherries for Gardens." The issue will be freely illustrated.

International Botanical Congress of 1915.—A very important part of the work of the Fourth International Botanical Congress, to be held in London in May, 1915, will be the consideration of nomenclature. This difficult subject remains over from the previous Congress, and it is of interest to both botanists and horticulturists. The Organising Committee consists of Sir David Prain, Professor Bower, and Professor Seward, while the Executive Committee is composed of Professor Farmer, Mr. A. W. Hill, Professor Keeble, Professor F. W. Oliver, Mr. A. G. Tansley, and Miss E. N. Thomas, with Sir Frank Crisp, Dr. Otto Stapf (Kew), and Dr. A. B. Rendle, British Museum, Cornwall Road, London, S.W. The latter is acting as general secretary, and to him should be forwarded all donations to the fund needed (£1,000) to carry out the Congress arrangements. A subscription of 15s. will entitle anyone to admission to the Congress, and to all its publications.

The Potato Crop in Germany.—A report dated September 26 has been received by the Board of Agriculture from His Majesty's Consul-General at Berlin stating that favourable reports of the German potato crop are being received from all parts of the country, and the damage caused by the unfavourable weather in August appears to have been greatly exaggerated in all preliminary estimates. In the opinion of the Consul-General, it is not yet possible to determine the quality of the crop. Some disease will undoubtedly be found, and unfavourable weather at this juncture would do much to impair the prospects.

Sir Rufus Isaacs.—The newly-appointed Lord Chief Justice of England is an ardent lover of flowers and of gardening. In the gardens surrounding his residence at Foxhill, Reading, he and Lady Isaacs possess a remarkably fine collection of roses, which they cultivate with skill, and in which they are keenly interest. Doubtless the new Lord Chief Justice will continue to turn with pleasure to his charming garden, after his arduous legal duties. Some time ago we gave several illustrations of the gardens at Foxhill.

Anglo-American Exposition, 1914.—A meeting of the Horticulture, Arboriculture, and Forestry Committee of the Anglo-American Exposition, 1914, was held on Tuesday afternoon at the Hotel Windsor, Victoria Street, S.W., when the Right Hon. Sir Herbert Maxwell, Bart., was unanimously elected chairman of the committee, and Mr. George Gordon, V.M.H., vice-chairman. Sub-committees were also formed for fruit, flowers, forestry, and sundries sections. It was decided that the gardens of the exhibition be completely transformed in a manner worthy of the occasion.

October Sweet Peas from Cadland Park.—October 18 is late for sweet peas in all but the cooler and moister parts of the kingdom, therefore we were surprised and delighted to receive a fine box of blooms on this date from Mr. Lewis Smith, The Gardens, Cadland Park, Fawley, Southampton. Mr. L. Smith not only cultivates sweet peas well at Fawley, as he did at Shotesham, but he is a raiser, and the flowers sent included a number of new seedlings, a brilliant salmon variety, deeper in tint than Barbara, being one of the most attractive. Both in colour and fragrance the flowers were delightful, and the varieties were Zarina Spencer, Mrs. Hugh Dickson, Lord Nelson Spencer, R. F. Felton, Princess Mary, Mrs. Warren (a waved Helen Pierce), Rosabelle, Melba, King Manoel, Clara Curtis, and Walter P. Wright. With the blooms Mr. Smith sent the following note: "Knowing your love for sweet peas a few blooms at this date may prove of interest. The flowers were all cut from plants which have been in bloom continuously since the second week in May. These plants are from ten feet to twelve feet high and bushels of flowers have been cut from them. We are decorating continually with sweet peas, and as the plants are as vigorous as ever they promise well for another month if the weather holds good. The seeds were sown last October, and the cultural methods followed have been precisely as I have advocated in The Gardeners' Magazine time after time."

Variability and Sportiveness of Lilium Leafage. — Mr. C. R. Scrase-Dickins, of Coolhurst, Horsham, recently exhibited a most interesting series of specimens of Lilium Sargentiæ before the meeting of the R.H.S. Scientific Committee. A bulb had last year produced a stem one part of which carried the foliage of L. Sargentiæ, and a part foliage similar to that of L. myriophyllum. This plant was grown from a bulbil, not from seed. This season offsets from it bore respectively foliage similar to that of L. Sargentiæ, L. myriophyllum, and partly of the one, partly of the other. The flowers were indistinguishable. It would seem that Mr. Scrase-Dickins had seen the passage of one species of lily into another, or that the breadth of foliage which is constantly used as a distinguishing feature of these plants is a character of less importance than it is usually considered. Mr. Elwes drew attention to the remarkable variation to be seen between lilies as one passes up the Formosan mountains, as though one species had produced forms adapted to the conditions under which they were growing, and regarded by botanists who had seen only collected plants as specifically distinct. Other characters in plants which had been used by herbarium botanists as a basis of classification were frequently variations of adaptation as seen in the field.

Changes in Secretaryship of National Sweet Pea Society.—In consequence of pressure of business Mr. Charles H. Curtis recently resigned the honorary secretaryship of the National Sweet Pea Society, a position he has ably filled since early in the year 1906 he succeeded Mr. H. J. Wright. At the annual meeting of the society, on Monday last, it became necessary to elect a successor to Mr. Curtis, and it was decided that a salaried officer be appointed. There were four nominations for the office, and eventually Mr. H. D. Tigwell secured the appointment, and to him, at Harrow View, Greenford, Middlesex, all communications concerning the society should be addressed.

Presentation to Mr. W. J. Pritchard. — At a largely-attended meeting of the members of the Elstree Horticultural Society, which was held a few evenings since, advantage was taken of the opportunity for presenting Mr. W. J. Pritchard, the hon. secretary, with a testimonial, in recognition of the splendid services he has rendered during the past five years. The testimonial took the form of a mahogany roll-top desk, and the presentation was made by the Rev. A. R. Eales, vicar of Elstree, who presided at the meeting. In asking Mr. Pritchard to accept the gift, Mr. Eales spoke in appreciative terms of the ability, courtesy, and energy he

evinced in the course of his work on behalf of the society. Mr. Pritchard acknowledged the testimonial in suitable terms. A beautiful gold chain was also presented to Mrs. Pritchard.

Postal Transmission of Plants to America.—The Board of Agriculture desire us to bring to the notice of nurserymen and exporters of plants that the importation of plants by post has been prohibited by the Government of the United States of America. The Board are also informed that the Horticultural Board of the Department of Agriculture, Washington, has ruled that orchids are included in the definition of nursery stock, and cannot, therefore, be imported without a certificate of freedom from disease.

Camberwell and the Crystal Palace.—There has been a rumour abroad to the effect that Camberwell would not fulfil its promise to contribute liberally towards the purchase of the Crystal Palace. At a meeting of ratepayers held on Tuesday evening last a resolution was carried asking the Borough Council to make a contribution of at least £15,000 towards the acquisition of the Crystal Palace.

Blue Water Lilies at Kew.—In the Victoria regia house at Kew the splendid flowers of the blue water lilies are a great attraction to visitors. Not only are the blooms of large size and lovely colours, but they are carried about eighteen inches above the water on short stems. Passing through the house a few days ago we counted nine expanded blooms of Nymphæ gigantea, and five of N. stellata. At Gunnersbury House Gardens these flowers are also very successfully cultivated.

Grants for Botanical Research.—The general committee of the British Association has appropriated the sum of £150 for botanical research. This sum has been allocated as follows: Prof. F. J. Oliver, structure of fossil plants, £15; Prof. A. C. Seward, Jurassic flora of Yorkshire, £5; Prof. F. Keeble, flora of peat of Kennet Valley, £15; Mr. A. G. Tansley, vegetation of Ditcham Park, £20; Prof. F. F. Blackman, physiology of heredity, £30; Prof. F. O. Bower, renting of Cinchona Botanic Station in Jamaica, £25; Prof. W. Bateson, breeding experiments with Œnotheras, £20.

New Recreation Grounds at Colne.—The Colne Corporation has purchased from Lord Derby sixteen acres of land at Judge Fields for the purpose of a new recreation ground. The sum paid was £4,000, and as the value of the land for building purposes was £1,000 per acre, Lord Derby sold the land to the Corporation for one-fourth its cost, and thereby made a gift of £12,000 to the town.

Trial of Horticultural Sundries.—The Council of the R.H.S. will continue their trials of horticultural sundries in 1914 under the scheme introduced in October, 1912. The system then adopted has proved admirable after twelve months' practical test, and sundriesmen are again invited to send their specialities (not more than three articles in any one year).

A WELL-FLOWERED SPECIMEN OF CYPRIPEDIUM PICTURATUM.

Exhibited by Sir Trevor Lawrence, Bart. (Mr. W. H. White, grower), at the R.H.S. Meeting on Tuesday.

THE NEW RACE OF ROSES.

In the opening year of the twentieth century the first of a new race of roses was presented to the public. It was the production of one of the most eminent of raisers of new roses of modern times, M. Pernet-Ducher, a raiser to whom rosarians are indebted for so many popular varieties, among which—to mention half a dozen—are Madame Abel Chatenay, Antoine Rivoire, Joseph Hill, Prince de Bulgarie, Madame Leon Pain, and Caroline Testout; and the class referred to is that which is known as "Pernetiana."

Pernetiana Roses.

To call a new class of roses after the name of the introducer, or originator, is no new thing. For instance, we have but to point to that comparatively new class of rambler, the original species of which was brought from Japan by Dr. Wichura; the class called Wichuraiana. Also, when, in 1817, M. Philippe Noisette obtained a new race of roses by crossing the musk rose with R. indica, of which Lamarque, Ophirie, Celine Forestier, and Marechal Niel are descendants, that series of roses, out of respect to its originator, was henceforth termed Noisette. So to-day, and for the same reason, this new race of yellow roses is called Pernetiana. In all three instances, Wichuraiana, Noisette, and Pernetiana, we give honour where honour is due.

And this is how the Pernetiana originated. In the botanical classification of the rose there is a pale yellow species, whose habitat is Asia Minor, and found growing chiefly in Armenia and Persia. It is called Rosa lutea. This species was brought to Europe by Miller, in 1768. Of the subspecies of R. lutea there are several, all bearing yellow flowers; the two best known are Austrian Copper and Austrian Yellow, introduced to England by John Gerard as far back as 1586. Seeing that both are natives of Asia Minor, not Austria, it is not easy to understand why the prefix "Austrian" was given them, unless Gerard attached the name of the country in which he purchased, or otherwise obtained them. Another sub-species is Harrisoni, a pale yellow semi-single, also a native of Asia Minor, introduced by Harrison in 1830. And there is another variety of R. lutea, whether sub-species or hybrid of species is an open question, brought from Persia by Willock in 1837, and called Persian Yellow, and from this Persian rose came the Pernetiana.

Development of the Race.

In the year 1900 M. Pernet-Ducher startled the rose world by bringing a perpetual-flowering orange-coloured hybrid of R. lutea, and known as Soleil d'Or, having as one of its parents Persian Yellow. It came a little before its time, because in those days if a rose did not possess the qualities of a so-called "exhibition" variety it was deemed of little worth, and Soleil d'Or is not one of this class. Nevertheless, the raiser worked on in patience, until, eight years later, he sent out another of the same, the Lyon Rose, a rose so remarkably distinct in colour and beautiful in form that it at once received universal admiration. The following year, A. R. Goodwin, another rose of the same class, and by the same raiser, appeared. In 1910 eight more varieties of the Pernetiana rose were placed on the market, the best of these being Rayon d'Or, Beauté de Lyon, by M. Pernet-Ducher, and Juliet, the production of Messrs. William Paul and Son. Thus the race was established, and will continue to be recognised as Pernetiana until an entirely new classification of the modern rose, so greatly desired, is adopted, and they are grouped according to the purpose for which they are best suited.

Although all Continental growers accept the name Pernetiana, nevertheless there are some rosarians here who have substituted such terms as "hybrid briar" or "Austrian briar." The former cognomen conveys nothing, and, as to the latter, one would ask why Austrian any more than Hungarian or Bulgarian, seeing that the progenitor of the race is a rose of Persian origin?

But by whatsoever term you now designate this race of glorious yellow roses, one thing will eventually happen, as it has already happened to other classes of the modern rose, its racial characteristics will, by interbreeding, disappear. The Pernetiana is now in its initial stage; definite and distinct is the race in the colour of the flowers, the glossy deep green foliage, the directness of the scattered prickles, and inflorescence. But signs are not lacking, even in the slight curving and basal thickening of the prickles, that varieties of the second and third filial generation are losing their distinctness. As with the hybrid perpetual, the tea, and the hybrid tea, so it will be with the Pernetiana race; the originator of the race may, perhaps, continue to give us pure-bred varieties, but it is very doubtful if others will.

With respect to the constitution of these pure-bred varieties. Coming from Asia Minor, where the atmosphere is hot and dry, R. lutea is not quite comfortable in the English climate. And, likewise, are some of the best varieties of the Pernetianas; they are tender, susceptible to damp and cold, and do not readily propagate by budding in the open. One refers in particular to Rayon d'Or and Louise Catherine Breslau. On the other hand, those that have less of R. lutea and more of other sorts in their composition, such at Beauté de Lyon, are quite at home in the English climate.

Some of the Pernetiana Roses.

Soleil d'Or (Pernet-Ducher, 1900).—Colour varying from orange-yellow to ruddy gold. Flowers of medium size, globular in bud, flat when open, short petals, confused centre like Persian Yellow, foliage bright green, growth vigorous.

Lyon Rose (Pernet-Ducher, 1908).—Colour varying from coral-shrimp to chrome-yellow. Flowers of large size, pointed, of good form and substance. One of the most popular of the series.

Entente Cordiale (Guillot, 1908).—Colour golden-yellow, shaded red. Flowers semi-double. Growth moderate, tender.

A. R. Goodwin (Pernet-Ducher, 1909).—Colour varying from coppery-orange to salmon-pink. Flowers of medium size, short petals, flat when open. Growth moderate. We have ceased to grow this rose in the open.

Beauté de Lyon (Pernet-Ducher, 1910).—Colour deep coral-red, remarkably distinct. Flowers resemble Soleil d'Or, but larger. Handsome dark green foliage, red prickles, mildew-proof. Not free-flowering. Growth very vigorous; makes a handsome shrub. It received the prize for the best French rose at Bagatelle in 1911. A very popular rose in France. It requires no pruning.

Johanisfeur (Turke, 1910). — Colour golden-yellow at base of petals, passing to bright red at tips. Flowers cupped, semi-double, produced from laterals. Growth long. Should not be pruned, but pegged down.

Juliet (William Paul and Son, 1910).—Colour remarkably distinct. Outside of petals old gold, inside brick-red. Flowers large and globular. Growth very vigorous. The long shoots should be bent over, not pruned. Mildew-proof. A popular rose.

Madame Ruan (Gravereaux, 1910).—Colour carmine, shading shrimp-pink to yellow at edges of petals.

Rayon d'Or (Pernet-Ducher, 1910.—Colour, Buds globular, yellow streaked with red, sunflower yellow when fully expanded. Flowers, deep-cupped, opening flat. Good growth, free and branching. Foliage bronze-green, glossy, mildew-proof. A handsome bedding rose. No pruning required. Tender. At the approach of winter the plants should be earthed up three or four inches at least above the junction where budded. The best of all the yellow roses. Excellent under glass.

Viscountess Enfield (Pernet-Ducher, 1910).—Colour, pale-pink, shaded yellow. Flowers deep-petalled, pointed; growth, tall, upright. Free-flowering under glass. We have ceased to grow this rose in the open.

Soleil d'Angers (Detriché, 1910).—A sport from Soleil d'Or, which it resembles in form of flower and habit, but not so good. Colour, deep yellow, edged with vermilion. We have ceased to grow this rose.

Deutschland (Kiese, 1910). — Colour, pale-yellow. Flowers short-petalled, medium size; growth long. Not free-flowering. We have ceased to grow this rose.

Louise Catherine Breslau (Pernet-Ducher, 1911).—Colour, deep coral-red, shaded coppery-orange. Flower large, semi-double, oval bud, opening flat. Red wood, glossy dark-green foliage. Mildew-proof. In growth and habit resembling Rayon d'Or. Promising.

The following are roses of 1913, and the descriptions are for the most part abridged from the raisers:

Cissie Easlea (Pernet-Ducher, 1913).—Colour, saffron-yellow, shaded carmine. Flowers globular. Foliage dark-green. Growth vigorous.

Madame Edouard Herriot (Pernet-Ducher, 1913).—Colour, coral-red, of the shade of Beauté de Lyon. Flowers medium size, semi-double.

Willowmere (Pernet-Ducher, 1913).—Colour, shrimp-pink, shaded yellow. Flower large, full, deep-petalled. Habit vigorous, branching. Called after the name of the house of Admiral Aaron Ward in Long Island, U.S.A. It is said to have first bloomed in this garden, where the winters are most severe.

Grand Duchesse Marie Adelaide (Soupert et Notting, 1913). — Colour, deep orange-yellow. Free-flowering. Growth erect. Vigorous.

Joseph H. Pemberton.

Salvia patens.—Beautiful as are many of the salvias, this old species is fully entitled to a place in the foremost rank, as the exquisite blue colour of its blossoms is admired by everyone. In some districts it is not hardy, but even where this is the case the tuberous roots can be readily stored in boxes of dry soil and kept safe from frost.—K.

ARCHES OF ROSES.

Some roses never appear to better advantage than when grown upon arches or over porches. Those with a natural tendency to droop show off the beauties of their large trusses or single blossoms to much better effect thus grown than when kept too dwarf or low. It is this habit that renders the majority of the Ayrshires, Boursaults, climbing polyanthas, and Wichuraianas so suitable for arches.

The main defect, up to quite recently, was the scarcity of blossoms produced after the first flush that almost all of our extra-vigorous growers give early in the season. To a certain extent this is unavoidable, from the fact that the majority of such varieties make extra long growths, from which they flower the following season. Although minus the wonderful showers of blossom we have the benefit of cleaner and more healthy foliage upon these ramblers than is generally the case with others. Few, indeed, are the roses that can compare in foliage with such as American Pillar, Gardenia, Ards Rover, Goldfinch, Reine Olga de Wurtemburg, Rêve d'Or, Tausendschon, Felicité Perpetué, Ruga, and Evergreen Gem.

Cultural Requirements.

Recently there have been some very welcome additions to the climbers by the sporting of several perpetual, or almost perpetual bloomers, and these have, fortunately, retained the greater part of their free-flowering qualities.

We must remember that in growing these strong-habited varieties there will be need of extra food. Not that they are in want of high culture, like some, but must have a good root run if they are to continue at their best. Yet we often find them with their roots much cramped, so much so that it is surprising they thrive so well as they do.

Pruning is a great feature in securing well-clothed arches. The greater part of this should be done late in the summer, and consists of cutting out as much of the older wood as possible. Generally one can remove the bulk of the young rods that have finished flowering, and thus give more room and light to those growing rods that will provide the chief display the following season. It is this judicious thinning that keeps the plants healthy and floriferous. When allowed to become overcrowded a quantity of useless and rapidly deteriorating wood must result.

A little before new spring growth commences I am much in favour of a good syringing with a rather stronger insecticide than would be safe later on. The wood will stand more powerful washes than young growth, and one may frequently kill the eggs of numerous insects as well as the germs of disease that would develop and spread all too quickly otherwise. While loose growths should be secured, to a certain extent, care is needed not to bundle these too closely together, or we not only lose much of the characteristic beauties of each variety, but contract and overcrowd the many leading trusses of blossom that would otherwise break from the best-matured wood.

I often come across cases where too little attention has been given to the permanent stability of arches upon which roses are grown. It does seem such a pity to find these weak and failing just when their support is most needed; but, without due precautions, this must invariably be the case. The material used, or the construction, need not be over-artistic and graceful. In the natural course of events we shall be covering most of this, and our main object should be stability. I am sure that not enough consideration is given to the enormous weight of quantities of heavily-foliaged growth, and more especially should wind and rain come together.

Choice Varieties.

Some care should be given as to whether a large quantity of blossom is wanted at any particular time, or a more or less continuous supply. As some little help here I have given the approximate date of the greatest display from those varieties only flowering well once in the season. There are some varieties much better suited for large and spreading arches than others. The climbing forms of Liberty, Richmond, Mrs. W. H. Cutbush, and Orleans are really grand for the less spreading arches and porches. Some of the most suitable for wide arches or those

ARCHES OF ROSES IN THE GARDENS OF OSIDGE,
The Southgate residence of Sir T. J. Lipton.

that are taller than usual will be found among the following, the main point of selection being in the colours most desired and the time of flowering.

Felicité Perpetué has been with us ever since 1828, and is still one of the best evergreen trailers. No matter what the weather this rose seems bound to succeed, beginning to flower early in July, and continuing all through the month. Small, rosette-shaped flowers of creamy-white are borne in semi-drooping trusses. Other good old favourites are Dundee Rambler and Bennett's Seedling, both of which flower at the same time, and much resemble the first in colouring. The Garland also opens early in July, carrying large trusses of fawn-coloured flowers, that turn creamy-white with age; of medium size, double, and thoroughly reliable.

Madame d'Arblay is a delicate flesh-white that flowers towards the end of June, while Flora is a still earlier bloomer, but with rosy-flesh flowers. Some good mid-June reds are Amadis or Crimson Boursault, and Gracilis. One of the best early whites is Queen of the Belgians. There are several others from these classes, but the above are most dependable.

We find a grand selection from the hybrid Wichuraianas, of which Dorothy Perkins and its various sports are good examples. White Dorothy, Christian Curle, Dorothy Dennison, and Lady Godiva; the last are soft flesh, all flowering during the second and third weeks of July. One of the most brilliant of all is found in Excelsa, which opens a little earlier and keeps on longer. For whites we cannot beat White Dorothy, Schneeball (July 10), Snowdrift (July 20), and the old Wichuraiana type, or alba, beginning to flower late in July, and continuing until stopped by frost. A very early red and blackish-purple is found in Diabolo. No collection of roses for arches can be complete without Hiawatha and American Pillar. Both commence to flower during the second week of July, and continue throughout the following month.

Hiawatha is a rich crimson with a white eye, small, borne in large pyramidal trusses, and with the grandest of foliage. American Pillar is large, a rich pink, with well-defined white eye and prominent golden stamens. Very showy foliage that seems exempt from mildew and red rust. In fact, we have no better grower. Both are single. In Una we have another grand single from the briars; pale buff, opening to pure white, a wonderful showy single where it takes.

Aimée Vibert scandens is an old friend (1828), and quite the best white from among the Noisettes; pure white when open, flowers in large clusters, always accompanied by clean green foliage, and flowering again in the autumn. A grand dark crimson to contrast with this is Graf Zeppelin, flowering very freely in large clusters, and continuously. For yellows over wide arches we may do well with Gardenia. A very sweet rose this, but only flowering well once. I have already alluded to its delightful foliage. Aviateur Bleriot is a saffron-yellow with a deeper centre, and retains its colour better than Gardenia or Robert Craig. For a larger flower one cannot do better than select Rêve d'Or, a good grower and continuous bloomer, that is almost sure to please if pruned carefully and only the older wood cut out.

Minnehaha and Delight, the first a double rosette-formed flower, and the last one of our clearest singles, both last longer than most, and carry exceptionally clean foliage. Some soft and pleasing blends of copper, salmon, and rose are found in Edmond Proust, Elisa Robichon, Francois Juranville, Joseph Billiard, Leontine Gervais, and Ruby Queen.

For more upright and narrow arches I would keep to the climbing polyanthas, although those already named may be made use of too. Scarcely anything can be better here than Blush Rambler, and its white sport, also Crimson Rambler. Electra and Goldfinch are two good yellows, but both, unfortunately, go much lighter in colour as they age. Waltham Bride is a good white. Grand deep reds are Climbing Liberty and Richmond, with Climbing Papa Gontier. Ards Rover is a dazzling crimson, shaded with maroon, and very perpetual. Reine Olga de Wurtemburg is difficult to beat as a deep and vivid red, and it is a continuous bloomer. Tausendschon, a rosy carmine-pink, has now produced a pretty, almost white sport, that will be very useful. William Allen Richardson is the most reliable of the deep orange-yellows, and generally does well.

It is useless to try any but exceptionally free-growing roses upon arches and porches, and one may safely select from any of those named above. Rosarian.

BUTTONHOLE ROSES.

Without doubt the rose is one of the most popular of all the flowers grown in this country, and deservedly so, for who is there who does not appreciate its charms, and as the flowers can now be had at all seasons of the year this makes them doubly valuable, especially as buttonhole flowers, which form one of the chief wares of the flower girls.

To many it is a source of wonder how such numbers of fine fresh blooms can be produced at the dullest period of the year, and sold at the prices they are at the present day. This could not have been done in years gone by. Our forefathers knew little or nothing about forcing roses by the thousand through the winter. It was not until we had cheap glass, the modern horticultural buildings, and the more scientific methods of heating, that such things became possible, and the rose advanced in popularity amongst the florists and general public. Thanks also to improved varieties and a better knowledge of the mode of treatment necessary to induce the plants to produce a profusion of flowers, we are now able to enjoy the beauty of these favourites at all seasons. Where houses can be set apart specially for the production of these flowers during the winter and early spring, there should be no difficulty in keeping up a supply of bloom, but the case is far different where the grower has to associate roses with other forced plants; it is then that the difficulty arises in keeping up a supply of bloom, and one cannot wonder should there be failures.

In the first place, before any attempt be made at forcing it is essential that the plants be well established, for one cannot reasonably expect a wealth of bloom from plants that have recently been lifted from the open ground; they should have been grown at least one season in pots before forcing is attempted. They should be stood in a sunny position out of doors, or, better still, be plunged, to save much watering. About the latter part of August these plants should be turned out of their pots, and, after the removal of a portion of the old soil, be repotted, using a rich compost consisting of about four parts of good turfy loam to one of dried cow manure; to this a liberal supply of dissolved bones may be added. The size of the pots used must be in accordance with that of the plants, but those from eight to twelve inches in diameter will usually be found most suitable; these should be well drained, so as to allow the water to pass away freely. When repotted they should be stood in the open until the new roots have become established in the new soil, which will be about the middle or latter part of October, when they should be pruned and housed ready for starting into growth. At this season of the year very little fire heat will be necessary, but as the weather gets colder it will require a greater amount to maintain healthy growth. Plants that have previously been forced and duly rested will start into growth much more readily than those which have not been so treated, therefore, it is always advisable where early blooms are required to use such.

Roses in their early stages of growth are very subject to both aphis and mildew, so a sharp look-out must be kept for these pests. It is not very difficult to rid plants of the former, as there are now so many good fumigants and insecticides on the market, but during the dull, sunless weather mildew is often prevalent, and unless this is kept in check the plants cannot thrive satisfactorily. Preventives are always preferable to cures, therefore, as a precaution, spray the plants once or twice a week with sulphide of potassium dissolved in water at the rate of about one ounce of the former to three gallons of the latter; this will prevent the mildew from doing any harm, and keep the foliage clean, which is a great advantage, as the blooms then develop much faster, and are finer. When the plants are in active growth it will be necessary to apply some stimulant, for roses are gross feeders; but this must be done with judgment, otherwise more harm than good will be the result.

There are now so many fine varieties suitable for buttonholes that to name a tithe of them would take up far too much space, and as most people have their own particular fancies as to shades of colour and shape of flower I shall only mention a few. Niphetos, in the bud, still holds its own as one of the best for early forcing, and its long-pointed, white buds are always appreciated. Bridesmaid is another good useful kind, of a clear pink colour. In Richmond we have a scarlet rose of good form that forces well. Madame Hoste is pale lemon-yellow, and good in every way. Madame Abel Chatenay, a bright carmine, is very popular; and Madame Falcot, a deep apricot; Lady Roberts, a coppery-red; L'Ideal, Sunburst, and Sunrise, and other good varieties. Where space can be afforded such kinds as W. A. Richardson may be grown, as they are pretty in the bud. It is, however, not the number of varieties that one need take into account, but the most profuse bloomers, and those best suited for the purpose. A mistake frequently made by private growers is trying to grow too many varieties, instead of contenting themselves with a few of the most useful. It is far better to grow a few well than attempt that which is beyond the means at disposal. H. C. Prinsep.

Michaelmas Daisies. — In the south-west of London the Michaelmas daisies have been far less satisfactory than in previous years. It was not that they flowered poorly, but just as they were at their best we experienced a spell of very hot weather accompanied with such a burning sunshine that the blooms shrivelled up completely, and in a few days their beauty was gone. I may say that I am entirely in accord with the opinion expressed on page 776, that, if limited to a single variety, Climax would be the selected one, as not only does it make a grand specimen, but the disposition of the sprays eminently fits it for cutting. —S. W.

CLAY'S FOR ROSES.

THE ROSES' CONFERENCE.

A council of Roses was summoned one day
To confer upon various topics,
When lengthy discussion protracted the stay
And the atmosphere glowed of the tropics.

But when, for a change, from colour and form
They passed to the subject of diet,
Unanimity banished all fear of a storm,
And noise was succeeded by quiet.

By common consent it was gladly agreed,
And fully recorded "nem con,"
That **CLAY'S FERTILIZER** is all that you need
To nourish all Roses upon.

This Plant Food of world-wide renown is indispensable for All Roses.
Exhibits grown by CLAY'S FERTILIZER catch the Judge's eye.

Sold everywhere in 6d. and 1s. Tins; and in Branded and Sealed Bags: 7 lbs., 2/6; 14 lbs., 4/6; 28 lbs., 7/6; 56 lbs., 12/6; 112 lbs., 20/-.
Or direct from the Works, Carriage Paid in the United Kingdom for Cash with Order (except **6d. Tins**).

THE BEST ROSES FOR STANDARDS.

Roses grown in standard form enjoy a high degree of popularity among all classes of lovers of the rose, and deservedly so. Specimens with highly-developed heads are not only very beautiful in themselves, but they add much to the charm of those parts of the garden in which the roses are grown by relieving the flatness characteristic of beds and borders devoted exclusively to dwarf plants. Unfortunately for the attractions of the garden and the peace of mind of the owner, standard roses are seldom seen at their best. Instead of being furnished with large, well-balanced heads, bearing a goodly number of finely-developed blooms, a considerable number of the standards coming under notice present a more or less starved appearance, and bear but few flowers, these latter being relatively small in size and of indifferent quality. These unsatisfactory results perplex not a few cultivators, but they are by no means difficult of explanation. To state the case in the fewest possible words, the failures that occur in the cultivation of roses as standards is due simply to a misconception of the chief essentials of success. One of the mistakes that is constantly being made, and that, perhaps, the most important, is the selection of varieties that are quite unsuited to this method. The other is the want of appreciation of the fact that the English briar, as, indeed, are all the stocks suitable for being worked at some distance from the ground, is a hungry plant. If these two essentials are borne in mind when purchasing and planting, and have practical expression given to them, failures now so common will soon be reduced to the vanishing point.

There are hundreds of varieties of roses in the catalogues, and of a considerable proportion of them standards are offered by the trade growers. As a consequence of so great a number of the varieties being obtainable as standards, the inexperienced assume that nearly, if not all the varieties are suitable for growing in such manner. It is not suggested that the nurserymen are responsible for the existing state of things. They are compelled by an inexorable law to provide for their clientele the classes of plants that are in general demand. They would, unless the writer is much mistaken, be only too glad to limit the number of varieties grown as standards and proportionately increase the stocks of those which can be successfully grown under the conditions that usually obtain in gardens. The best varieties, and these only should be selected for growing in this way, are those possessing great vigour, combined with a somewhat branching growth and freedom of flowering. If the growth is not strong, the plants appear to fail in drawing up through the stocks the moisture and nutrient matter essential to their full development. They certainly make an attenuated growth, and present within a short period of their being planted a "sticky" and otherwise miserable appearance, which is retained until they are rooted out and consigned to the rubbish heap or fire. A free-branching habit is not less essential than a strong constitution, for when a few stout rods are produced in association with a number of small shoots, well-balanced heads and an abundant production of flowers are impossibilities.

The English briars, as do other roses suitable for use as stocks for standard roses, require a moderately rich and deeply-cultivated soil. They also thrive most satisfactorily in soil that is best known as a heavy loam, as evidenced by the remarkably vigorous growth made in a wild state when the roots have the run of soil that contains a moderate percentage of clay. Should the soil be light, owing to the large percentage of sand, add a quantity of clayey loam, if available. A layer about six inches thickness spread over the surface will be the most suitable, and to this should be added before the digging is commenced a similar quantity of well-rotted manure and leaf-mould in about equal proportions. Should the clayey loam not be available use the leaf-mould and manure in a slightly increased quantity. In the preparation of strong loams first spread over the surface a layer four or five inches in thickness of partially-rotted manure from the stable or farmyard, and apply bone superphosphate or finely-ground bones at the rate of 6 or 7oz. to the square yard. In all cases break up the soil to a depth of two feet, and well incorporate the manure chiefly with the bottom spit. Should the subsoil be very sandy, or stony, or consist of clay, and be less than two feet from the surface, remove enough to give the roots of the roses two feet of good soil and replace with such suitable compost as may be available. The planting should be done as early in November as practicable, the soil being trodden very firmly about the roots, and stake at once to prevent their being swayed about.

The following varieties are of exceptional merit for standard culture, and

A FINE GROUP OF ROSE FLORENCE PEMBERTON.

Grown in standard form at Kew. The blooms are a rich cream colour. (See page 802.)

can be recommended as the best in their several shades. They are, indeed, so good that not until they have been given a place in the garden should others be selected. Captain Hayward, H.P., bright red, not so continuous in flowering as could be desired; Caroline Testout, H.T., pink; Frau Karl Druschki, pure white; Florence Pemberton, H.T., rich cream colour; General McArthur, H.T., scarlet-crimson; Gustave Grunnerwald, H.T., bright carmine-pink; Hugh Dickson, scarlet; Lady Ashtown, H.P., deep pink; Lady Hillingdon, rich orange, passing to bright yellow; Lady Roberts, T., yellow, with apricot centre; La Tosca, H.T., cream, suffused blush; Madame Abel Chatenay, H.T., rich rose-pink; Madame Ravary, H.T., yellow, passing to cream-white with orange centre; Madame Jean Dupuy, H.T., light yellow; Marie Van Houtte, T., bright lemon-yellow; Molly Sharman Crawford, T., white; and Suzanne Marie Rodocanachi, H.P., bright rose. G.

ROSES FOR BEDS AND SMALL BORDERS.

Now that we have such an immense variety of roses the owner of a small garden finds much difficulty in allowing space for the yearly addition of some new varieties. For this reason an annual overhauling is necessary to bring the collection up to date. Many persons prefer a whole bed or border filled with one special variety, which provides a glorious mass of colour and flower. It is doubtful, however, if this is the best way of utilising space, or for providing a continual supply of bloom. Many varieties that give the best results in a mass are not so perpetual-flowering as others; therefore, although they may have the desired effect at one period, they are neither so interesting nor so useful.

For this reason mixed planting has its advantages. One can have masses of colour by including three, or even more, plants of one variety, and by a judicious arrangement of colours. This method of planting in variety is most interesting when strolling round the garden, and comparing varieties with friends, which is really one of the great charms of a garden. When the massing of one variety only in a bed or border is employed all we can say is we get a brilliant display of colour, which can be seen at a distance, but it does not provide equal interest on a close inspection.

However, that all may participate in the two methods of planting I will give a selection of varieties for massing and for planting in variety. The former may be made more interesting by the introduction of standards or half-standards in the same bed or border, as these add to the flowering mass, and also relieve the flatness of dwarf varieties.

The dwarf polyantha varieties are useful in providing continuously a quantity of flower, and also in hiding the soil near the edge of the beds or borders. Many growers plant too sparingly, and leave so much space between the roses that they are tempted to include other things, such as violas, mignonette, etc., which may serve the purpose of hiding the soil, but are not an advantage to roses.

Varieties for Massing.

The best H.P. varieties are Captain Hayward, scarlet-crimson; Frau Karl Druschki, white; Gloide de Chedane Guinoisseau, vermilion-red; Hugh Dickson, crimson—the long growths of this variety should be pegged down; Madame Gabriel Luizet, silvery-pink; Marquise de Castellane, clear rose; Tom Wood, cherry-red; and Victor Hugo, dark crimson.

Hybrid Teas.—Arthur R. Goodwin, coppery orange-red; British Queen, pure white; Chateau de Clos Vougeot, velvety-scarlet; Dorothy Page Roberts, coppery-pink; Duchess of Wellington, saffron-yellow; Ecarlate, brilliant scarlet, extra free and continuous; General MacArthur, bright crimson, especially sweet; Lady Battersea, cherry-crimson; Kaiserin Augusta Victoria, pale primrose, requires extra thick planting; Killarney, flesh, shaded white; Lady Pirrie, coppery-salmon, perpetual-flowering, strong grower; Madame Abel Chatenay, carmine-rose; Madame Jules Grolez, China rose; Marquise de Salisbury, velvety-red; Mrs. Edward Powell, velvety-crimson; Richmond, bright red - scarlet; Viscountess Folkestone, creamy-pink; Caroline Testout, bright rose; and Cheshunt Scarlet.

Tea-scented.—Corallina, deep rose, extremely good in autumn; G. Nabonnand, pale flesh, shaded yellow; and General Schablikine, coppery-rose. Rayon d'Or, sunflower yellow, flushed outside with crimson, is one of the finest roses ever raised for massing.

Dwarf Polyanthas.—Aschenbrodel, peach, with salmon centre; Aeunchen Muller, rose; Canarienvogel, golden yellow and orange; Boskoop Baby, china rose; Jessie, bright cherry-crimson, rather tall, like Orleans Rose in that respect, but free flowering, geranium red in colour; Ellen Poulsen, rich pink; Rodhatte, cherry-red; Gruss an Aachen, yellowish-red; Iceberg, pure white; Mrs. W. H. Cutbush, pink, shaded rose; Yvonne Rabier, white, sulphur-yellow centre; and Tip-Top, coppery-pink, yellow centre.

The best standards are Frau Karl Druschki, Caroline Testout, General MacArthur, Madame Abel Chatenay, and Ulrich Brunner.

For Mixed Beds.

In addition to the varieties noted above the following are especially desirable, embracing the cream of the new sorts (except those very expensive), and the best of older kinds. I have not named many hybrid perpetuals, as they do not flower in the autumn like the hybrid teas, and, therefore, are not so valuable: Horace Vernet, velvety-red; Hugh Watson, crimson, shaded carmine; Madame Gabriel Luizet, silvery-pink; Margaret Dickson, white, flesh centre; Mrs. A. M. Vierker, cerise; and Mrs. John Laing, soft pink.

Hybrid Teas.—Avoca, crimson-scarlet; Betty, coppery-rose, delightful for cutting; Carine, coppery-salmon; Countess of Gosford, salmon-pink rose; Countess of Shaftesbury, silvery-carmine; Dorothy Ratcliffe, coral-red, shaded yellow; Duchess of Westminster, madder-rose; Edward Mawley, velvety-crimson, quite one of the best garden roses raised; Florence Edith Coulthwaite, deep cream, stippled rose; Florence Haswell Veitch, brilliant scarlet, shaded black; G. C. Waud, orange vermilion; George Dickson, velvety scarlet-crimson, quite the finest dark rose yet raised; James Coey, deep golden-yellow; Jonkheer J. L. Mock, carmine, changing to imperial pink; Lady Ashtown, pale Rose du Barri; Lady Greenall, saffron-orange; La France, bright pink, still unsurpassed for perfume; Leslie Holland, deep scarlet-crimson; Lieut. Chaure, velvety crimson-red; Lyon Rose, shrimp pink, salmon shaded; Mabel Drew, deep cream and canary-yellow; Madame Melanie Soupert, salmon-yellow, suffused carmine; Margaret Molyneux, saffron-yellow, shaded apricot; Melody, deep saffron-yellow, with primrose-yellow; Mrs. Alfred Tate, coppery-red, shaded fawn; Mrs. Cornwallis West, pure white, flushed pink, especially sweet; Mrs. Peter Blair, lemon-chrome, golden-yellow centre; Mrs. Theodore Roosevelt, creamy-white, centre rose; Prince de Bulgarie, rosy-flesh, shaded salmon; and St. Helena, cream, with pink blush in centre.

Tea-scented Varieties.—Alexander Hill Gray, deep lemon-yellow; Dr. Grill, clear rose, so useful for cutting or buttonhole wear; Lady Hillingdon, apricot-yellow; Lady Roberts, apricot, shaded orange; Madame Lambard, bright rose; Molly Sharman Crawford, eau de nil white; Mrs. Foley Hobbs, ivory-white, tinged pink; and Mrs. Herbert Stevens, white, fawn, and peach shaded towards the centre.

Soil Preparation.

Soil preparation is important. Light loamy soils require little labour, as compared to heavy ones. Deep digging and the addition of plenty of half-rotted cow manure is all that is required. Soil of a sandy character should have an addition of clay mixed with the soil at planting time.

Stiff, heavy, cold, retentive soils that are not actually clay, but closely approach it, usually have an impervious subsoil, which, if not broken up, is all against success, as it provides a hard pan, through which the water from heavy rains cannot percolate during the winter and early spring, at a time when the roses are dormant. Such soils, and clays, when properly prepared, grow excellent roses. A month before planting trench the soil quite a yard deep, breaking up the bottom of each trench. Keep the surface soil in the same relative position, and add to the top spit half-decayed stable manure in quantity. If long strawy manure or road sidings are available they may be added to the lower trenches to assist porosity. A two-inch thickness of wood ashes, old potting soil, or decayed vegetable matter spread over the surface when trenching is complete will assist quick rooting when the plants are put in. If half-rotted turf can be had at planting time a small portion given to each tree will be an advantage.

Early planting is an advantage, as new roots are formed at once before the soil becomes cold. The end of October or early in November is the most suitable period. Take off the points of any long shoots at planting time to prevent the plants being loosened in the soil by wind, and stake standards securely. A thin mulching of manure about the plants in light soil, and of leaf-soil or decayed vegetable refuse in the case of plants in heavy soil, will keep roses snug for the winter, but I object to heavy manure in quantity on the surface of stiff soil, as it excludes air and warmth from the sun. Light bracken, straw, or even soil, drawn up around the collar of each plant, is best for protection.

Swanmore Park. E. Molyneux.

Selecting Pears for Planting.

—When selecting varieties choose only the very best to keep up a long supply, and unless the soil and climate are good, plant late varieties very sparingly, as these rarely ever come to perfection. Do not plant for the sake of variety, but enough of each of the best to produce a good supply. Williams' Bon Chretien, Triomphe de Vienne, Beurre d'Amanlis, Marguerite Marillat, Conference, Marie Louise, Pitmaston Duchesse, Doyenne du Comice (plenty of this), Durondeau, Charles Ernest, Emile d'Heyst, Beurre Hardy, Beurre Superfin, Glou Morceau, Josephine de Malines, Beurre Perran, Nouvelle Fulvie, and Le Lectier, etc., will grow well in the bush form in favourable districts. —H. Markham.

ROSES FOR PILLARS.

Among the many varieties of roses now in cultivation there is so much variation in habit of growth, as well as in the form and colour of the flowers, that it is possible to obtain varieties suitable to almost any purpose and situation. The type now under consideration—pillar roses—comes about midway between the dwarfs and the vigorous climbers, and the section includes some of the most beautiful roses. I think the section has been neglected, to a certain extent, since the Wichuraianas have come so much to the front. Without descrying the merits in the least of this latter popular type, there is not the slightest doubt but that it has often been planted where space does not allow full development, whereas there may have been ample room for a pillar variety.

What is desirable in a pillar rose is a character of growth that allows it to furnish a pillar to the height of about six feet or so without a tendency to produce too vigorous shoots, which would get out of bounds. Such roses are most useful for the upright pillars of verandahs, pergolas, and for low walls and trelliswork. They are seen to great advantage when trained to stout stakes, and in this manner they are very effective if arranged at intervals towards the back of herbaceous borders, or when grouped in a sheltered spot on lawns, selecting the more vigorous varieties to form the centre of the group. An arrangement I saw during the present season of several plants distributed evenly in a large bed, with a carpeting of violas, was very striking, as also was another with a groundwork of pegged-down Wichuraianas beneath them.

The cultural requirements of pillar roses are much in common with that of other kinds. It will be understood that they will differ constitutionally, as they originate from various classes, and some are much hardier and more robust than others. Roses require a well-drained soil in which to thrive, and if this important condition does not occur naturally it must be provided artificially before success can be anticipated; and as some of the choicest pillar roses are vigorous varieties of teas, hybrid teas, and noisettes, the importance of this matter will be understood. Such roses delight generally in a rich and moderately light soil of good depth, and no trouble should be spared in preparing the sites before planting. Fungoid attacks upon roses are much aggravated by unsuitable conditions of the soil. It frequently happens that pockets have to be formed at the foot of the supporting pillars of verandahs, etc., and it is essential in such instances, in addition to providing good drainage, to take care that the soil does not become dry, as they are not always in a position where the rain has full access to them.

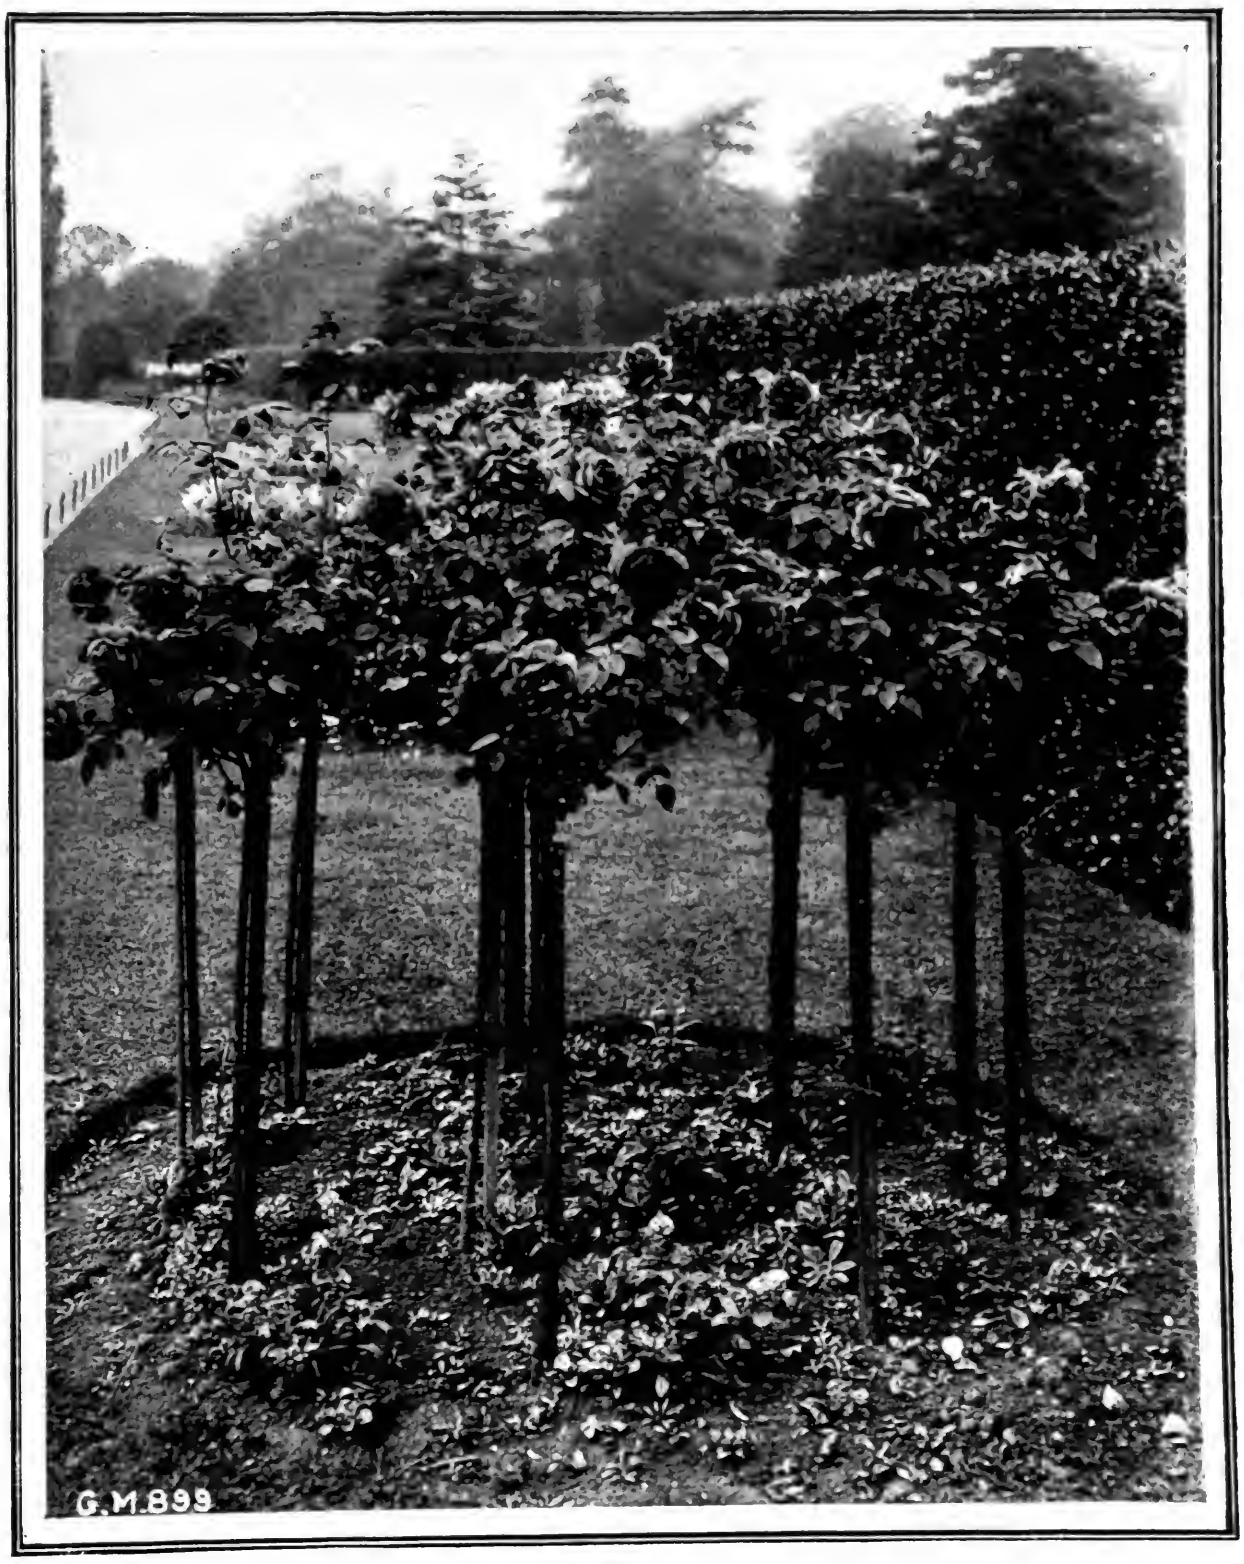
Established specimens are much benefited by occasional applications of some special rose manure during the growing season, and in the autumn a quantity of the surface soil should be removed, and new loam given, to which coarse bonemeal has been added. This treatment is most necessary to roses growing in a restricted root run.

Pruning pillar roses is an operation which exacts due attention. Young plants, the first spring after planting, must be pruned back hard to induce basal growth; the following season the work consists of cutting out all weak and old wood, and shortening back young shoots not required for extension. Securing the shoots, either by tying or nailing, is of importance, and in summer this will need regular attention.

Tea and hybrid tea roses of vigorous habit provide us with some very choice pillar varieties, and the following are reliable kinds in most districts: Madame Abel Carriere, Francois Crouse, Lady Waterlow, Gruss an Teplitz, Ards Pillar, Bardou Job, Waltham Climber, and Noella Nabonnand, while the climbing counterparts of the varieties Caroline Testout, Captain Christy, and K. A. Victoria are very desirable. Amongst the noisettes and their hybrids are several very free-flowering varieties adapted for pillars; some are rather tender and require a warm position, but the varieties Celine Forestier, Fellenberg, Alister Stella Gray, Longworth Rambler, Carmine Pillar, Charles Lawson, and Coupe d'Hebe thrive in most localities, while La marque, W. A. Richardson, L'Ideal, and Bouquet d'Or generally require some shelter. Madame Issac Periere and Marie Pare are two effective Bourbons, which rarely fail. Conrad F. Meyer, a Rugosa hybrid, makes an ideal pillar rose, invariably producing its fragrant flowers until Christmas. Climbing Cramoisie Superieure is a most continuous bloomer of rich colour. Several varieties of Penzance briars can be used with good effect, and their single flowers are generally admired; Amy Robsart, Anne of Geierstein, Refulgence, and Meg Merrilies are a few of the best.

One might give a much longer list of suitable varieties, but the majority of those mentioned can be depended upon. During severe weather it is advisable to afford roses of the tea and noisette sections a little protection, and pieces of bracken entwined amongst the stems is recommended for the purpose. T. B. Field.

Wych Place Gardens.



AN EFFECTIVE GROUP OF ROSE HUGH DICKSON,

Grown as standards at Kew. The flowers rich scarlet, and the illustration represents the group at an early period of the flowering season. (See page 802.)

Helenium Riverton Gem. — I consider this to be one of the finest border flowers brought forward within recent years, as it both grows and flowers freely. The warm terra-cotta tint of the flowers, with their reddish suffusion, form a particularly showy feature, so different in tint from the yellow-flowered composites and the Michaelmas daisies which go to form the bulk of outdoor flowers at this season.—T.

NEW ROSES OF THE YEAR.

Rosarians who take a special interest in roses of recent introduction will this year have no cause to complain of a slackening of effort on the part of raisers in their endeavour to maintain liberal supplies of novelties. So far from this being the case, their activities have been maintained at a high level, and these have been so successful as to place at the disposal of the rose-loving community a large number of new varieties possessing much merit. It may be that those who are conservative in their views with regard to roses may consider the number rather too large, but, in the opinion of the writer, this cannot well be the case, provided they are sufficiently high in quality to justify their inclusion in a representative selection. That those which have received awards during the past season from the National Rose Society or the Royal Horticultural Society may be so described there can be no doubt. With reference to these, it may be said that while any one cultivator may not require the whole number, or any considerable proportion thereof, there does not appear to be one that can well be spared. In the olden days, when roses, on their introduction, were judged solely from the exhibition standpoint, the case was different. Then there were but few types that engaged the attention of cultivators, and the estimate of the varieties was based upon the size, form, and colour of the flowers. It was, therefore, difficult to obtain in a selection of twelve or more varieties the necessary degree of distinctness. Now there are many types, each of which has its proper place in the garden, and, in the case of the majority, the growth receives hardly less consideration than do the flowers. There are, as so well known, both exhibition and garden roses, and the latter comprise several sections, all more or less necessary to the proper furnishing of the rose garden or to the production of attractive and continuous displays of bloom in the flower garden. Hence the possibility of having numerous varieties without the risk of their being in excess of requirements, or of a difficulty, in selecting from the novelties, of obtaining some that are too much alike. Of the novelties that were shown at the exhibitions of the National Rose Society at Gloucester, Regent's Park, and Westminster, thirty-one received awards, these comprising fifteen gold medals, nine silver-gilt medals, and eight cards of commendation.

H.T. ROSE MRS. F. W. VANDERBILT.

Flowers yellow, suffused rose-pink, orange centre. N.R.S. Gold Medal at Gloucester, July 15. Messrs. S. McGredy and Son.

(See page 805.)

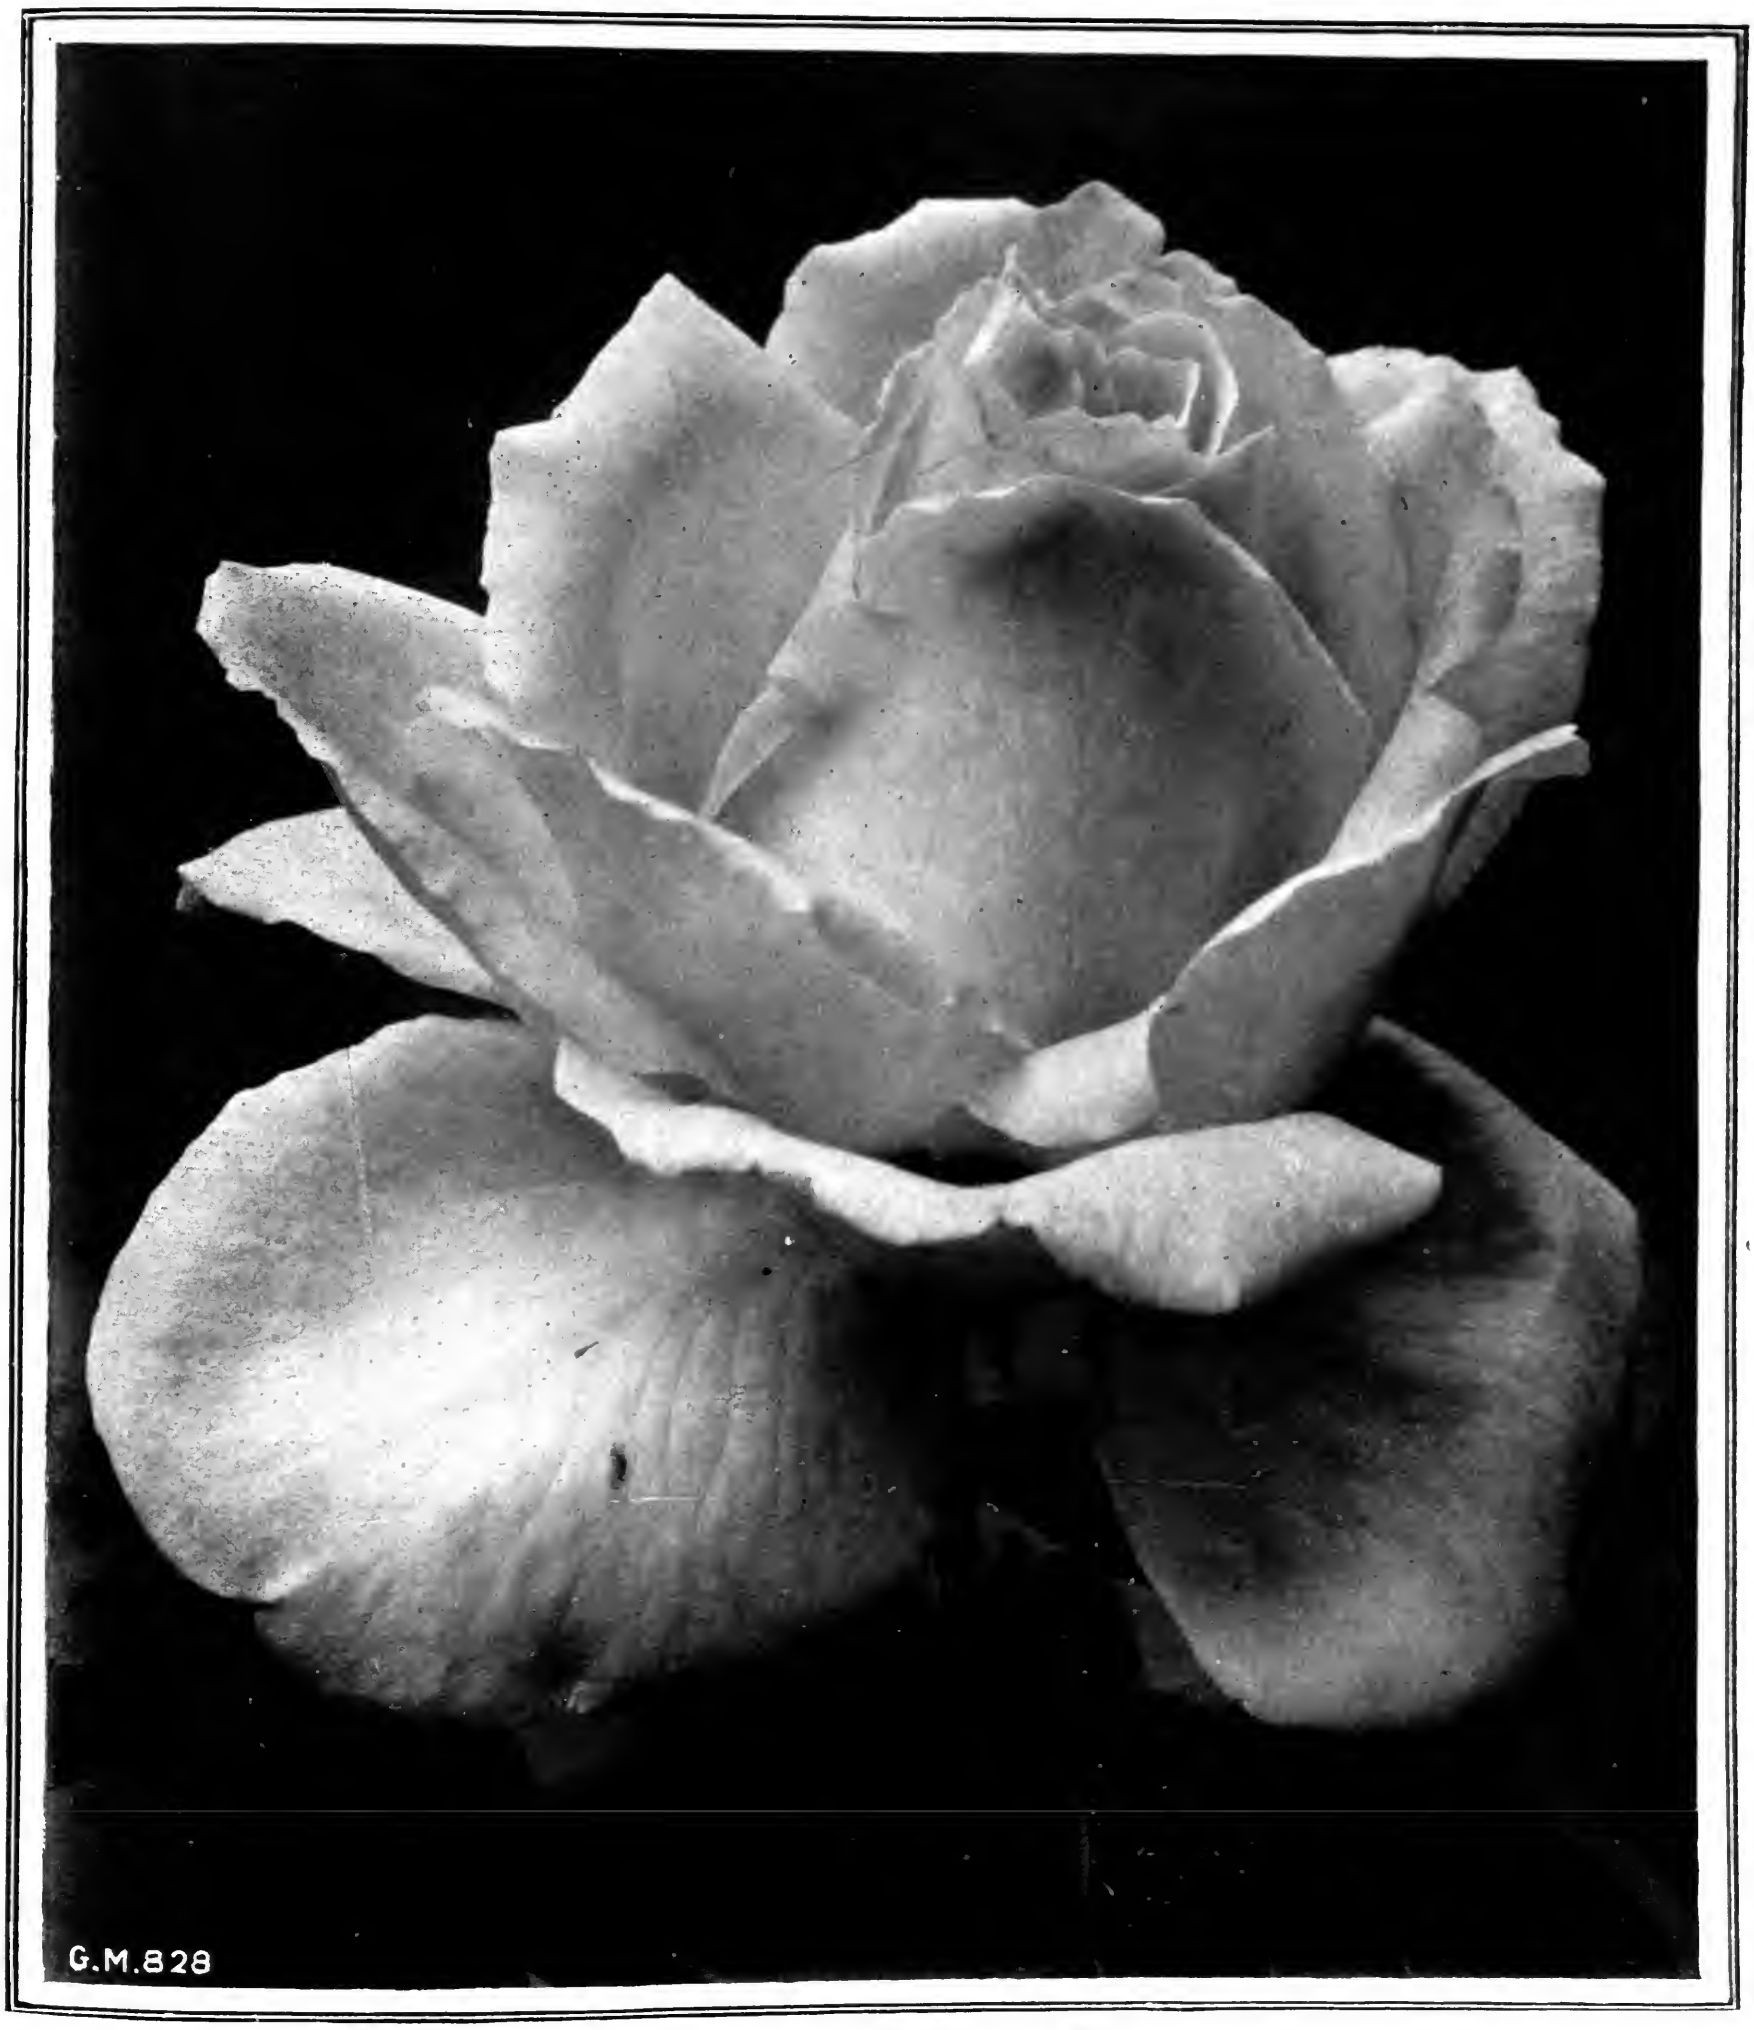
Gold Medal Roses.

The middle of July appears to have been more favourable to raisers for presenting their new varieties to public notice than the first week, for whereas but four roses

were awarded gold medals at the exhibition held in the gardens of the Royal Botanic Garden on July 4, seven received this high distinction at the Gloucester Show held on July 15. Especially conspicuous among the gold medal roses exhibited at Regent's Park was Queen Mary, raised by Messrs. Alex. Dickson and Sons, Newtownards, and unquestionably one of the most distinct and beautiful of the decorative roses of recent introduction. The blooms are above the medium size, fairly full, and the colouring is exquisite, the basal half of the petals being golden-yellow, and the upper half brilliant rose. Mrs. Forde (H.T.), from the same firm, is a pleasing soft yellow flower of high quality. The other two gold medal roses at this show were Brilliant (H.T.) and Mrs. J. Lynas, both of which were raised by Messrs. Hugh Dickson, Lim., Belfast. Brilliant is an important addition to the dark hybrid teas, for the blooms are of large size, with broad petals, and the colour is vivid scarlet-crimson. Mrs. J. Lynas is a fine exhibition rose, the blooms large, deep, and full, and the colour a pleasing pink hue, with a rose shading.

At the Gloucester exhibition four roses submitted by Messrs. S. McGredy and Son, Portadown, received the distinction of a gold medal, and these were Colleen (H.T.), Florence Forrester (H.T.), Iona Herdman (H.T.), and Mrs. F. W. Vanderbilt (H.T.). Colleen is a very beautiful flower, of good depth, with fine petals, and of a bright pink hue. Florence Forrester is a superb white variety that should quickly take a foremost place among the white roses. The blooms are of large size, fine form, and pleasantly fragrant. Iona Herdman may be described as a valuable addition to the decorative roses, being remarkable for its effective colour. In the latter respect it reminds one of Old Gold, but is much more intense. Mrs. F. W. Vanderbilt was first exhibited at the National Rose Society's Metropolitan exhibition in 1912, when it received a silver-gilt medal, and surprised not a few rosarians that it did not receive the higher award. The blooms are rather above the medium size, the petals are yellow suffused with rose-pink, and the centre rich orange-red, this colour extending some distance along the well-marked veins.

Very fine are Countess Clanwilliam (H.T.), Georgeous (H.T.), and Mrs. Archie Gray (H.T.), for which Messrs. Hugh Dickson, Lim., were awarded gold medals at



H.T. ROSE ANNIE CRAWFORD.

Flowers bright pink. A.M., R.H.S., July 29. Mr. R. W. Hammond, Burgess Hill. (See page 806.)

Gloucester, and when distributed they can hardly fail to take a high position among the many beautiful roses that have been raised by the firm. Countess Clanwilliam has the promise of proving a valuable addition to the exhibition H.T.'s; the blooms are of large size and superb form, and the colour cream, delightfuly suffused with pink. Gorgeous (H.T.) is a highly attractive rose, the blooms large, and the colour rich pink with orange suffusion. Mrs. Archie Gray is distinct in character and colour, and decidedly beautiful. The colour is bright lemon, and the flowers have a pronounced fragrance.

G. Amedee Hammond (H.T.) is an important addition to the yellow roses, and should bring fame to Messrs. Alex. Dickson and Sons, with whom it originated.

H.T. ROSE MRS. FORDE.

Flowers reduced, the colour pale yellow. N.R.S. Gold Medal, July 4. Messrs. A. Dickson and Sons, Newtownards. (See page 805.)

The blooms are large, and of fine form, and the colour is golden-yellow in the centre passing to light yellow in the other petals.

Edward Bohane (H.T.), which obtained a gold medal at the National Rose Society's autumn show, is a distinct and handsome variety, vigorous in growth, and free in flowering. The individual blooms are of large size, superb form, and the colour rose-red suffused bright red. Red Letter Day (H.T.) will appeal strongly to those who have a predilection for single roses, being distinct in character, and highly effective. The blooms are rather large, and the petals are of great breadth, and remarkable for their substance; the colour crimson-red. These were raised by Messrs. A. Dickson and Sons. Moonlight (H.T.), the beautiful cluster rose, which has recently been described and illustrated in these pages, was another of the fine roses that received the distinction of a gold medal, and it is interesting as placing the Rev. J. H. Pemberton, Havering-atte-Bower, Romford, in the forefront of raisers.

Edgar M. Burnett, H.T., has the promise of proving a most useful addition to the exhibition varieties of its class, and is one of the most notable roses raised by Messrs. S. McGredy and Son. The flowers are of large size, with stout petals of great breadth, and the colour is a delightful shade of pink. Muriel Dickson, H.T., is a superb variety, belonging to the hybrid briar or Pernetiana race, and merits attention for its attractive colouring, as well as for its fine shape. The blooms are of average size, and have finely-developed petals; the colour brilliant rose-red with a golden hue at the base of the petals. This was raised by Messrs. Hugh Dickson, Lim.

Silver-Gilt Medal Roses.

Eight roses received the distinction of a silver-gilt medal from the National Rose Society, and of these two—Muriel Dickson and Red Letter Day—were given the higher award of a gold medal at the Society's autumn show. The varieties, in addition to the two mentioned, are Mrs. Ambrose Ricardo, H.T., a beautiful exhibition flower, large in size, and globular in form, the colour pale cream, suffused lemon-yellow at the base of the petals, raised by Messrs. S. McGredy and Son; William Cooper, H.T., a finely-formed flower of large size, and of a deep red-rose hue; Mrs. J. W. Parker, H.T., a very beautiful variety with large, deep, elegant flowers of a rich blush colour; and Ulster Gem, a handsome decorative variety, the flowers large, single, and of a bright yellow hue. These have been raised by Messrs. Hugh Dickson, Lim. Mrs. George Norwood, H.T., raised by Mr. A. J. Hicks, Twyford, is a superb exhibition variety, the blooms large, of superb form, and very fragrant, the colour rich rose. Eileen Smiley, H.T., was finely exhibited at Gloucester by Messrs. McGredy and Son, and is a notable addition to the decorative roses; the colour is rich orange. Last, but by no means least, is Conway Jones, H.T., a brilliantly-coloured and splendidly-formed flower, raised by Messrs. Alex. Dickson and Sons, that will not fail to render good service on the exhibition stage.

Award of Merit Roses.

A goodly number of roses received recognition from the Royal Horticultural Society in the course of the past summer. These comprised Ophelia, H.T., one of the beautiful varieties raised by Messrs. William Paul and Son; the flowers are large, the buds long and pointed, and the colour a delightful combination of cream and flesh-pink. Mrs. W. Sargent, H.T., a distinct variety with large cream-white flowers; Mrs. Godfrey Brown, H.T., a charming rose of high quality, the colour flesh-tinted with rose shading on the outer side of the petals; Muriel Dickson, H.T., described under gold medal roses; and Ulster Standard, H.T., an effective single variety with brilliant crimson flowers. These were raised by Messrs. Hugh Dickson, Lim. Annie Crawford, H.P., was unquestionably one of the most noteworthy of the roses submitted to the Royal Horticultural Society, and was so splendidly shown by Mr. W. R. Hammond, of Burgess Hill, as to at once attract attention. The flowers are of the largest size, with great depth and fine petals, and the colour soft clear pink. The variety was raised by Dr. J. Campbell Hall, and can hardly fail to greatly enhance his reputation as a raiser. The remarkably beautiful white hybrid tea, Mrs. Andrew Carnegie, for which the raisers, Messrs. W. Cocker and Sons, Aberdeen, received the National Rose Society's gold medal in 1912, had an award of merit made in its favour at the R.H.S. meeting held on August 26.

We were much impressed by the beautiful yellow decorative rose, Mrs. G. Beckwith, exhibited at the National Rose Society's autumn show by Messrs. Beckwith and Son, Hoddesdon. The flowers are of medium size, full, and of a rich yellow colour, the foliage is good, and the variety should prove of much value for the production of flowers for decorative purposes in a cut state.

G. G.

VARIATION IN OAK LEAVES

To those interested in arboreal "sports," in which the foliage of well-known trees have been greatly varied in form, size, and make, generally by sports or mutation, a visit to the collection of such varieties in the oak, in Kew Gardens, cannot fail to be of interest.

This collection of probably a hundred or more is located near the river bank, and is reached by skirting the gardens directly from the main entrance, and turning to the left when the river comes into view. On either hand then we pass through a double row of oak trees of moderate size, on each of which, when inspected, the foliage will be found to differ, imitating closely in many cases the foliage of quite different species, by being deeply cut, lengthened, or shortened, and otherwise rendered very dissimilar to the ordinary form. Labels are attached to each variety indicating, as a rule, the type of leaf imitated.

C. T. D.

ROSES IN POTS.

Where suitable glass accommodation is available few plants give more satisfaction to the cultivator than roses. But to grow them with any large measure of success houses must be specially devoted to them. A mistake which is often made by the inexperienced is that of growing too many varieties. It is a much better plan to grow three or four well-tried sorts, choosing the colours which are most desirable for decorative purposes.

To be successful with early forcing the roses must be well established in their pots, and the wood be thoroughly ripened before placing them in the forcing house. Such plants should now be in an exposed situation outdoors, where they must remain until the time comes for placing them indoors. This time will, of course, be governed by the date at which flowers are required. Before placing them indoors remove a little of the surface soil, and top-dress with loam, old lime rubble, and bone-meal. In most private establishments no attempt is made to force roses till early spring, when the chances of failure are few, provided their cultural requirements are well attended to.

Pruning pot roses required for very early forcing should not be done until the wood is quite ripe; the growths should then be cut back to three or four eyes. An important point to remember when the roses are in active growth is to remove all the less promising shoots, and especially those which are growing in the centre of the plants. Very little pruning will then be required beyond the shortening back of the young wood.

Air must be very carefully admitted at all times, and unless the conditions outdoors are very favourable the top ventilators only should be used. Mildew is one of the worst enemies, and the grower will be wise to anticipate an attack of this troublesome pest by using flowers of sulphur freely about the house, especially near the hot-water pipes. Grubs also must be sought after, and picked off by hand when found. A mild fumigating with a nicotine compound will keep the plants free from aphis. During fine weather the foliage must be syringed with rain water, the temperature of which must not be lower than that of the house. During the early stages of growth water must be given with great care; later on, when growth and roots are more active, it may be given more liberally, and when the flower buds are forming stimulants must be given. Diluted liquid farmyard manure, sootwater, and guano may be given alternately.

After flowering the requirements of pot roses must be attended to just as assiduously as before, for it is then that the flowering wood for another season is developed. Those which have been forced early should be repotted in spring or early summer, and plunged outdoors, removing all flower buds as they appear. The later plants need not be potted until the autumn. Plants for late spring blooming may be dug up and potted now, plunging the pots in ashes up to the rims. Should very severe weather set in the roots must be covered with short litter, and some dry material be placed over the heads.

The climbing roses need similar treatment to the teas and hybrids in regard to their general cultural requirements. In this case the pruning consists chiefly in shortening hard back two or three of the weakest shoots to encourage strong growths from the base. After flowering the old flowering wood must be cut out to make room for the young shoots. At this stage the plants must be repotted, and plunged outdoors.

Pot roses of great merit are now fairly numerous, but a rigid selection has to be made in most places. Among H.P.'s the best are Captain Hayward, Frau Karl Druschki, Mrs. J. Laing, General Jacqueminot, and Ulrich Brunner. Good H.T.'s are Caroline Testout, Lady Faire, Liberty, Madame Abel Chatenay, Mrs. A. R. Waddell, Mrs. David Jardine, Richmond, Sunburst, Lady Hillingdon, and White Killarney. Of tea-scented roses a few of special value are Bridesmaid, Catherine Mermet, Madame Hoste, Souvenir de Pierre Notting, The Bride, Niphetos, and White Maman Cochet. Mrs. W. H. Cuthush is a capital dwarf polyantha variety for pot culture, and Ellen Poulsen promises well. Where space permits such rambling varieties as Dorothy Perkins, White Dorothy, Hiawatha, American Pillar, Coquette, and Mrs. Flight should be chosen, as they are most useful in bold decorations.

Lockinge Park Gardens. E. Harriss.

H.T. ROSE MRS. GEORGE BECKWITH.

Flowers rich yellow. Raised by M. Pernet-Ducher, and introduced by Messrs. G. Beckwith and Son, Hoddesdon. (See page 803.)

AMONG THE ALPINE FLOWERS.

"O come at last, to whom the spring-tide's hope
Looked for through blossoms, what has thou for me?"

At this season the lover of alpines is as the gleaner, going through the fields to gather up the few fragments left by the hand of the reaper. The rock garden cannot vie with the border in brilliancy and in beauty. Its loveliness is subdued, for its glory is over for the time, and it shrinks into a modest retirement, waiting for the sweet spring, when the alpine flowers seem doubly dear. Yet the true lover of the rock garden seeks to garner some treasures, however few they may be, and he loves to dwell upon their beauties and their virtues.

Zauschneria californica.

Perched on a prominent terrace stands the brilliant Californian zauschneria, or the "humming bird's trumpet," as it is popularly called. A very precious flower it is indeed, as it waves in the autumn winds, and cheers us as we pass it by or linger to look at its bright scarlet, trumpet-shaped blooms. It is a true treasure, which all should own where they can give it plenty of sun, and the light, dry, stony soil it seems to love. Of the various forms in cultivation one should be eschewed by all, save those in the warmer parts. This, which has hairy or pubescent leaves and branches, seldom comes into bloom timeously. The one here is different, and

this season it came into flower before August had entered upon its last week, and it saw September through. It is one of the most precious of autumnal alpines, growing here to a foot high, or a little more, and bearing in wonderful profusion its bright scarlet flowers. It is increased by cuttings, and a good group would be a bright feature in the large rock garden anywhere.

Polygonum vaccinifolium.

Another most valuable autumn rock garden flower is Polygonum vaccinifolium, whose little spikes of pink are so pleasing rising from the carpet of neat, glossy green leaves given by the plant. It is a charming thing for trailing over rockwork, and, when once established in a congenial place, not at all difficult to grow. The saving clause is necessary, however, as it is not too easy to establish, and it is not always that we hit at once on a place this beautiful little knotweed enjoys. Time after time has one lost plants which one thought were going on happily, but it is never wise to give up the attempt to cultivate a good flower because of a failure, or, for that matter, several failures. So it is best to try P. vaccinifolium again and again. One discovers that it does best here on a low part of the rock garden, where its trailing branches can hug the ground and the stones, where the soil is not too dry, and where the rays of the sun do not reach it too long in the day. It is facing north-east here, and is in a moist sandy loam, with a large admixture of sand. Here it has been established for some eight years, and is annually increasing in size and in attraction. Experience teaches that P. vaccinifolium dislikes a draught, and that it may be injured by hard frosts when in a position of this kind.

Colchicum Sibthorpi.

This lovely meadow saffron has been very scarce for a long time, but I am glad to see that it is now once more plentiful, and that it is being offered at a low price for a plant of its kind. It is by far the finest of the chequered meadow saffrons, or colchicums, the handsome flowers being beautifully chequered, chess-board fashion, on a ground hue which is much prettier and more delightful than that of the sister-chequered Colchicum variegatum. I think, however, that C. Sibthorpi is a little more tender than C. variegatum, and that it should be planted six inches deep in a more sheltered place than is required for its less refined and more plentiful sister flower, C. variegatum. These meadow saffrons are fast coming into favour for the rock garden in autumn. Good clumps are of the greatest worth there, and among them none will be more delightful than Sibthorp's meadow saffron.

Plumbago Larpentæ.

It comes hard to part from the above well-known name, not at all difficult to negotiate, and of which the popular name of "Lady Larpent's Leadwort" is such a good translation into our English tongue. But botanists tell us that Ceratostigma plumbaginoides is its proper name, and we who use the simple one are liable to be set down as "unscientific." So be it! We are quite content to lie under the accusation, so long as we can admire our flower and call it by a name which can be repeated by the many. It is a lovely late autumn rock plant indeed. Its exquisite flowers of blue look all the finer when they are associated with the wonderful colouring of the leaves themselves. One cannot hope to give any impression of these dying tints. They must be seen to be realised, but one would commend Lady Larpent's leadwort to the notice of all who cherish the rock garden plants, especially those which come to cheer us as we are passing into the darkness of winter, and which appear to say: "We come to greet you, and to remind you that soon our sisters of the spring will gladden your longing eyes."

Other Flowers.

As we wander round we see many other flowers still—most of them blossoms which have been for long with us, but which are willing to bide awhile.

Here is one of our chief favourites, Androsace lanuginosa, cheery as it was months ago. There, in the moraine, are some pinks which have been blooming away for months. Here, again, on the rockwork are others of the race, bright, though less plentiful than of yore. Stray helianthemums, and especially the double red H. amabile fl. pl., and its golden sport, Jubilee, are bright and useful; some geums yet give their showy blossoms; the campanulas are still in flower, as represented by the garganica varieties; several of the carpathica forms, and a late seedling of C. rotundifolia alpina, with a few more. Of the carpathica forms White Star is unusually fine at present. There are alyssums, erodiums, geraniums, violas, tunicas, Silene Schaftæ, Cyclamen neapolitanum, oxalises, with a few sedums and other flowers. Truly the alpine lover is not yet forlorn because many of his flowers have bid a long farewell. S. Arnott.

NOTES FROM SCOTLAND.

The Past Season.

Not for many years has the country generally been favoured with such a fine season as the present. The western districts in particular, noted for their superabundant rainfall, have special cause for satisfaction. Never were finer displays of autumn flowers seen. In this respect, the early-flowering chrysanthemums have been, and, in many cases, at present date (October 10), still are, very conspicuous, while many autumn-flowering subjects have closed their natural period of bloom and beauty unharmed by frost or other untoward circumstance. What are generally classed as summer bedders, i.e., pelargoniums, calceolarias, and a whole host of others, have revelled in the warm, dry atmosphere that has for long prevailed, and even now present, in many cases, very pleasing pictures of slowly-departing glory, as though reluctant to leave a scene that has been so well suited to them.

In the Glasgow public parks great numbers of the summer and autumn-flowering chrysanthemums, both single and double-flowered varieties, are grown, and, for the most part, rigid selection is carried out among the many, and the best retained. These, planted upon lengthy borders, or in plots, with due regard and forethought as to height and colour effect, have, in most instances, given unbounded satisfaction to all privileged to view them. To hint that this is entirely due to good culture would be misleading, though such is the primary cause, but much must be attributed to the introduction in quite recent years of so many new and beautiful varieties, far surpassing in habit of growth, earliness, and colour those so much in vogue but a decade ago.

Hollyhocks.

This stately flower appears to be again returning to favour, especially for the embellishment of public resorts. Large numbers have this year been in evidence in Camphill Gardens, the splendid adjunct to Queen's Park, Glasgow, and, judging by the still larger number of seedling plants being grown for next year, their culture will be much further extended. These, of course, will not, when in flower, compare very favourably with the splendid named varieties of forty or more years ago, yet vast improvement has of late years been made, and a strain of seedlings may now be obtained that will make a splendid display, single and double flowers, and great variety of colouring being represented.

Pentstemons.

The almost astounding advance and improvement that has been accomplished by raisers in this useful autumn-flowering plant has provided a new feature well in keeping with the shrubbery or wide stretches of greensward. More particularly does this apply to public parks or gardens, where display, as growing, is the main object. It may be remarked that the pentstemon is of little or no use as a cut flower, the spikes, however well they may be grown, lasting but a short time when severed from the plant and placed in water. Varieties are now numerous, and almost any colour or combination can be selected from the trade list of the specialist, according to the requirements or tastes of the grower. Moreover, the flowers withstand adverse weather conditions of wind and rain, also a few degrees of frost, very well, and with the exception of the chrysanthemum, they are sometimes the most conspicuous objects of the parterre late in the season.

I have in mind a rather narrow, semi-circular bed upon a grass-covered slope, with a compact edging of white-flowered heather, and in the centre, throughout its length, well-developed plants of the deep scarlet P. Southgate Gem, which for weeks past have provided a feast of floral beauty, and, even now, though subject to frost on two occasions, they are not without charm and interest. This is one excellent pentstemon of very distinct character, and there are many others obtainable equally free-flowering. The shrubby variety, Newbury Gem, scarlet, with its white and pink forms, is hardy in most districts, and is more useful for vase decoration, to which purpose its slender flower stems and verdant foliage lend themselves.

Cuttings of pentstemons, inserted under cover of a cold frame at this season, quickly strike root in a sandy compost. Protection by mats or other convenient mode of covering in very severe weather is all that will be required to ensure safety until the time for planting out returns.

James Day.

A Beautiful Tamarisk. — Few among our hardy shrubs form such a delightful feature during the latter part of the summer as a tamarisk, which is known by several names. When first especial attention was directed towards it, a dozen years or so ago, the tamarisk in question was known as Tamarix hispida æstivalis. After a time, however, we were assured that this name was not the correct one, which was Tamarix Pallasi rosea, and as such it is given in the Kew Hand List of trees and shrubs. Yet another change is now evidently thought desirable, as it is for the future to be known as Tamarix pentandra—at all events till that is superseded. These continual changes are a regular worry, and lead one to think that our botanical friends do not know their own mind.—K.

DICKSON'S

'HAWLMARK' CHAMPION IRISH ROSES FOR 1913

are now being offered in strong plants.
These superb Novelties have excited universal admiration wherever seen.
They are the best introductions of 1913.

BARR'S SPECIAL BULB PLANTER.
Rd. 548091.

Specially designed for planting Daffodils and other bulbs in grass. This tool cuts and lifts a clean circular piece of turf, which is released from the cup when the second hole is made, and lies ready at hand to fill in the holes when the bulbs have been put in, it being only necessary to remove a little of the soil from the bottom of the sod. By its use a large quantity of bulbs may be planted in a very short time, and without the least disturbance of the sward. The cup is manufactured from high-class hardened steel, and always carries a keen cutting edge. 10s. 6d. each.—BARR and SONS, 11, 12, and 13, King Street, Covent Garden, London.

MICHAELMAS DAISIES AT TAPLOW.

There is a peculiar charm about the flowers that come in autumn, when the shortening days and chilly evenings, the falling leaves, and other familiar signs remind us that summer has passed, and winter is drawing near. The flowers of spring thrill us with the joy of anticipation, whilst the autumn flowers engage us just at the time of shortening days and the dulness associated therewith.

Autumn flowers are by no means lacking in beauty of form of delightful colouring, a fact that is fully demonstrated at Messrs. Barr and Sons' new nurseries at Taplow.

Michaelmas daisies were, at the time of my visit just in the height of their season. An extensive collection is grown, and one realised whilst examining the many varieties how great has been the improvement effected in this family. No longer need we have straggly, untidy plants bearing flowers of indifferent colour, for among the newer varieties we have large-flowered, bright-coloured varieties, and dwarf, compact-growing kinds that produce myriads of tiny starry flowers that glisten like jewels on graceful branching stems, as useful for cutting as they are delightful in the border. The varieties of Aster ericoides and A. vimineus are general favourites, and, indeed, it would be surprising to find a lover of flowers who does not admire the daintiness and charm of these small but wonderfully floriferous types. A. vimineus Delight was one of the first to be noted, the plants forming symmetrical bushes nearly three feet in height, and from the groundline to the extremity of the branching stems there would scarcely be room to place an additional blossom. When first the flowers open they reveal a clear yellow disc, which gradually changes colour until it becomes almost chocolate-brown, old and young flowers combined thus presenting an effective diversity of colour. A. vimineus Lovely is almost a rose-pink, with a suspicion of mauve that is very pretty. This, also, is a very free variety, while Milky Way, growing in a good mass, appeared, as seen from a distance, like a billowy cloud just touching the earth. One might suppose a variety bearing this name would be white, but it is quite pink, and is perfectly charming. Of taller growth, and somewhat different habit is A. vimineus Bianca. The main stems rise to about four or four and a-half feet high, and branching horizontally from the stout main stem are numerous branchlets of considerable length, clothed with regular rows of white, yellow-centred flowers. The plants make a pyramid of flowers, graceful and effective. Somewhat on similar lines is A. vimineus Maidenhood, the flowers of which are large for this section. Bright red is still something of a scarcity in the aster family, but one or two varieties of the Novæ-Angliæ section are of really good colour. Mrs. J. F. Rayner is probably the richest in hue, and my notes record it as being a bold variety with crimson flowers, produced on stiff, erect stems, which are well clothed with the soft, somewhat woolly leaves which are characteristic of this section. A good mass of red is particularly welcome in the garden at this season of the year, and Aster Mrs. J. F. Rayner is therefore to be well recommended.

In the Novi-Belgii section we find a number of the most striking of the lavender and blue shades. The flowers are for the most part fairly large, and the growth is vigorous. Munstead Purple is very rich in colour, and, with its dark foliage and ruddy stems, it stands out well, especially when surrounded with white-flowered varieties or with yellow chrysanthemums. St. Egwin is a most beautiful variety, its dwarf, erect, and sturdy habit, and its clean, fresh-looking pink flowers, produced in large symmetrical heads, are quite distinct from those of other asters, and, as far as I have seen, there are few varieties that surpass it. If, however, I were obliged to make a choice of only one variety of the Novi-Belgii section, Climax would have the preference. This very closely approaches perfection. Its individual flowers are large, beautifully formed, with long, clear-coloured, almost azure-blue flowers with bright yellow disc, and they are produced in such numbers that even a single plant is conspicuous from a considerable distance. To see this fine aster at its best it should be grown on single stems. Each plant should be securely held to a firm but inconspicuous stake, and, if liberal treatment is afforded, the plants will branch out from the main stem in such a manner that when in full bloom they are literally pyramids of blue flowers standing at a height of five feet or so.

Several other excellent varieties were noted at Taplow, some of which are quite new, but mention of them must be somewhat brief. Glory of Colwall, one of Mr. Ballard's new semi-doubles, was flowering freely, as also was Peggy Ballard, a pleasing rosy-lavender flower of large size. Beauty of Colwall, Keston Blue, and a new variety of Coombe Fischacre named Brightness, are all distinct, and worthy of inclusion in the most select collections. Quite an old favourite, but still charming plant, is A. diffusus horizontalis, and for lightness and grace nothing can surpass A. cordifolius Ideal, the best of this section. No difficulty would be experienced in writing a lengthy article on other subjects that were making the nurseries gay, although the month of October was well advanced, and there had been heavy storms that one might have thought would have robbed most flowers of their charm. All that can at the moment be done, however, is to mention some of the plants that were so striking that visitors may well make note of should occasion arise to make a selection of hardy plants for late blooming. Glowing masses of rich orange and scarlet were provided by some of the smaller kniphofias, such as Macowani, Obelisk, Torchlight, and Ophir. Sutherlandia frutescens is a very decorative subject with tubular flowers suggestive of coral, and finely-cut foliage. Several choice varieties of Anemone japonica were very good. Alice, Queen Charlotte, Coronation, and Coupe d'Argent being among the best. Cimicifuga simplex, with its spikes of creamy-white flowers, was very attractive, and the collection of autumn-flowering crocus contained so many lovely little gems that justice could only be done them by writing of their charms at some length.

VISITOR.

APPLE LEAF-SPOT.

According to the "Journal" of the Board of Agriculture, this disease (Sphæropsis malorum, Peck) is the cause of serious injury to the apple, pear, and quince in the United States, where it has been recognised for a considerable time. It has only recently been reported as occurring in this country, although in all probability it has always been present, and has been passed over as being one of the other better-known fungi attacking our fruit trees.

The trunk, branches, leaves, and fruit are attacked. On the trunk and branches the fungus causes a roughening of the bark, either as local patches, or extending for a considerable distance, destroying the bark and exposing the wood. When a branch is girdled, the portion above the wound dies. It also occurs on slender twigs.

The fungus causes a brown rot of the fruit, commencing as a small spot which usually spreads over the whole fruit. The fruit may be attacked while on the tree, but the fungus is most abundant on fallen fruit, where it produces spores in great abundance, which infect the tree the following season. In this country it has so far only been observed on apple and pear, more especially the former, and is most frequent on the leaves and young branches.

On the leaves the first indication of infection is the presence of minute, dark purple spots, which gradually increase in size, usually retaining a more or less circular outline, reaching up to half an inch in diameter. Very frequently neighbouring spots coalesce, forming irregularly-shaped blotches. When old, the blotches are rusty-brown in colour, the central portion often being of a lead colour. Usually only after infected leaves have been lying on the ground for some time, very minute black points, the fruit of the fungus, are scattered over the central portion of the patches. Leaves that are infected fall early in the season, and if this defoliation is continued each season, as is almost certain to be the case unless preventive measures are taken, the trees become injured, and the fruit small and poor in quality.

No very large canker wounds have been observed in this country, but young twigs are attacked, the infected areas being indicated by the bark becoming dry and much cracked, and the epidermis or skin being lifted up and torn into shreds. On such diseased areas the perithecia, or fruit of the fungus, can be seen during the winter months, and it is mainly due to the spores produced on dead twigs that the leaves become infected in the spring. Scott and Rorer, who have investigated this disease in the United States, say that it occurs abundantly on dead twigs and branches in nearly every orchard, producing spores in enormous numbers. This is, perhaps, the most fertile source of infection for both fruit and foliage. In old orchards, particularly where pruning is neglected, the leaf-spot disease is much worse than in young orchards. The leaves of young trees adjacent to an old orchard become more spotted with the disease than those further removed.

These observations clearly indicate that the prompt removal of dead branches and shoots is a matter of primary importance in checking the disease. The fallen diseased fruit should also be collected and destroyed. It is not at all certain that the spores on diseased fruit eaten by pigs or other animals are killed. Numerous spores are also produced on fallen, diseased leaves, a fact that it is well to remember, although it has been stated that the collection of such leaves is impracticable.

However carefully the trees may have been pruned, and fallen diseased material destroyed, many spores are certain to remain on and around the trees. To prevent these from infecting the young leaves the trees should be sprayed with Bordeaux mixture, half strength. A first spraying should be made about a week after the petals have fallen, and a second about a month later. Self-boiled lime-sulphur wash may be used for spraying instead of Bordeaux mixture.

The perithecia are immersed in the substance of the matrix, the minute mouth or opening through which the spores escape just rupturing the epidermis of the leaf, and showing as a black point on the surface. The spores are elliptical, dark coloured, and average 25 × 12μ.

The blotches formed on apple and pear leaves by the scab fungus, Venturia inæqualis, Aderh. (=Fusicladium dendriticum, Fckl.), are readily distinguished from those due to the fungus under consideration, by the ill-defined blotches being blackish or olive in colour, and by the spores not being produced in perithecia.

Gladioli.—In most districts gladioli appear to have been very satisfactory this season, and undoubtedly the fine weather experienced contributed largely to this, the conditions being adverse to the spreading of disease to which the plants are subjected, consequently it was not nearly so prevalent as it has been in some former seasons. The corms should now be lifted and removed to a dry, airy shed; after a short time, when the soil and foliage have become dry, they should be cleaned off, and the bulbs put into bags or boxes and stored away where they will be safe from frost and damp.—T. B. FIELD.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

SEASONABLE REMARKS.—With shorter days and cooler weather both morning and evening, there is perhaps greater difficulty in maintaining the desired atmospheric conditions than is found in the depth of winter. when the weather outside is more settled and the fluctuation in temperature is not so great as at the present season. I pointed out quite recently that it was not desirable to damp the floors, staging, etc., before the normal temperature in the different departments had been reached. I would now draw attention to the condition of the amosphere outside, which, in the north-eastern counties at any rate, has been practically saturated with moisture for nearly a month. Such conditions, with very little sun and scarcely wind enough to move the foliage on the trees, render very little damping or watering necessary. With a lack of moving air stagnation is possible unless a discreet use is made of the heating apparatus. There is no occasion to use excessive heat, but there should be enough to permit the opening of the ventilators, and so secure a buoyant atmosphere.

TEMPERATURE.—The temperature in the different divisions should now be gradually reduced, so that by the end of the month the usual winter reading may be arrived at with the least possible check. The sun will have sufficient power to raise the temperature very considerably, where the air is clear; this will assist in drying up moisture, and help considerably to mature the growths.

RESTING.—Many of the deciduous orchids will now have matured their growths. Thunias which have shed their leaves should be examined for insect pests, and after these have been removed the old growths may be cut away and the plants placed in a dry, airy position; no water will be necessary until the turn of the days, and the new growths make their appearance. Practically the whole of the dendrobiums will now have reached maturity. Drier and more airy conditions should be afforded, and only sufficient root moisture be given to keep the pseudo-bulbs plump. Plants that have not completed growth should be placed at once under the warmest conditions obtainable to induce them to complete growth as soon as possible.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

POINSETTIAS.—Having completed their growth, these are commencing to develop their bracts, and must be kept in a temperature of 60 to 65 degrees by night, and a little more by day; overhead spraying must cease, and only occasional damping of walls, paths, etc., be given. It should be borne in mind that as the bracts develop the plants are fast approaching a dormant state, and consequently water must be applied with the greatest care, otherwise a loss of foliage is bound to ensue. Manurial applications also must cease. When the bracts have developed, to keep them in good condition as long as possible, the temperature may be reduced to 55 degrees, and the atmosphere be kept practically dry.

EUPHORBIA JACQUINIÆFLORA will require similar conditions and treatment to poinsettias, but, as this plant is slower in developing its racemes of flowers, it will require the higher temperature for a week or two longer.

CENTROPOGON LUCYANUS.—The effect of the beautiful spell of fine autumn weather is most apparent on this subject; this season the plants have made splendid growth, and are now fast developing their flowers. It is not too late to give them a last application of manure, either in liquid form or as a top-dressing, but this should be done at once. We prefer to mix equal parts of an approved fertiliser, finely sifted soil, and soot together, and give as a top-dressing about a dessertspoonful to each plant. Allow plenty of room. Water only when the plants are dry, otherwise they are apt to collapse entirely. A temperature not lower than 65 degrees will suit them best until the flowers are fully developed, when it may be allowed to recede to 60 degrees.

BEGONIA GLOIRE DE SCEAUX.—This beautiful late winter-flowering begonia is now developing apace, and a few plants, given the necessary room for full development, will require a large amount of house-room. At the same time, this is quite necessary, for, if cramped for space, they will become badly drawn, and produce a few flowers only on the top instead of making symmetrical pyramids with beautiful metallic foliage, studded within a few inches of the pot with the lovely pink flowers. We find them flower more freely when grown in 6-inch pots; after these are filled with roots a fortnightly application of soot, fertiliser, and soil, as recommended above for centropogons, is given. A temperature of 60 to 65 degrees by night and slightly higher by day will now suit them, giving, whenever possible, a little ventilation.—H. Prime, Hatfield Gardens.

FRUITS UNDER GLASS.

LATE PEARS AND PLUMS under glass will now be cleared of fruit. The season has been so favourable to the ripening of the wood that the trees should now be removed to the open air. Peaches, plums, pears, etc., which have ripened their wood under glass, will stand any reasonable amount of frost so long as they remain dormant. Place them in a position sheltered if possible from north and east winds; the spaces between the pots should be well packed with fern or litter to keep out frost, and they will then take very little harm through the winter, provided the soil is moist. The worst enemies at this season are birds and worms; the birds can be kept away by means of small-meshed netting, and the site the trees are stood on must be made firm, on ashes, and, as a further protection, a tile or slate should be placed under each pot.

POTTING.—Late trees may still be reduced, as recommended in the calendar of September 27, and repotted into fresh compost. Care should be taken not to force these late-potted trees, but, with careful handling, they will fruit well next season. Any young trees which were lifted last autumn, pinched, and otherwise specially prepared for potting up, may now be taken up and placed in pots from 8 to 10 inches in diameter. All stone fruits and pears like a fairly heavy, calcareous loam, well fortified with burnt earth, old lime rubble, bones, and soot, in preference to much animal manure of any kind. These trees cannot well be made too firm by ramming. The latest trees of Coe's Golden Drop plum should also be taken in hand, the roots being well moistened prior to potting; 12 to 14-inch pots are quite large enough for the ordinary run of trees. Such trees are best put in the open air, and, as they will not be required for forcing, new roots will be active enough by the time they are required.

STRAWBERRIES.—Pay careful attention to the watering of these plants, especially during dry, windy weather, as the pots will now be crowded with roots. If allowed to get dry, no after management can make good the injury done. Keep the pots clear of weeds, and see that the roots do not make their way into the material the pots are standing on. The best place for some time yet is right out in the open; indeed, it is a good plan to place strawberries on a trellis platform until frost and snow come, when they will need to be plunged up to their pot rims in ashes. It is a great mistake to house strawberries too early.

LATE MELONS.—The latest batch should be grown in pots, and, in order to impart as much flavour as possible at this date, a high temperature and fairly dry atmosphere must be maintained; 70 to 73 degrees at night is suitable, and a little ventilation should be given early in the day when the temperature reaches 78 to 80 degrees. Close early, and so secure a temperature of 85 degrees. Caution is also required in watering to avoid cracking in the fruits. Melons will keep sound much longer at this late season when cut than earlier in the season.—F. Jordan, Warter Priory Gardens.

THE FLOWER GARDEN.

HERBACEOUS BORDERS.—Most herbaceous plants have now passed out of flower, and the borders should receive immediate attention. Where plants have become overcrowded or weak, they should be taken up and the ground deeply dug and well manured. The stools of most kinds must be divided before they are planted again, and pieces from quite the outside should be selected for that purpose; this method is the only satisfactory one to adopt when dealing with borders which are in an overgrown or bad state. Where the conditions do not justify such drastic measures, all dead stems, etc., should be cut away, and any strong-growing kinds which are encroaching beyond their limit should be reduced. Make up all weak and vacant places, and afterwards fork in a good dressing of rotten manure between the plants. An effort should be made to have the various subjects correctly named. When wooden labels are used they require renewing frequently; iron or zinc labels with raised letters are to be preferred for the purpose, as they last for years.

LAWNS.—During the past two months grass has made exceptional growth, and consequently lawn mowing has needed constant attention. Should the weather continue mild the grass will still keep growing, but it is not often necessary or advisable to mow after the end of the present month. Worn turf on tennis courts and other playing lawns should be made good, and any uneven parts should also be levelled up; by carrying out such work at this time of the year it has several months in which to settle down before being used next season. Spongy and loose turf will be much improved if frequently swept and well rolled throughout the winter months.

THE ROSE GARDEN.—Roses resemble other deciduous shrubs in being benefited by early planting, and all preparations should be made to forward this operation as much as possible. When contemplating new plantations the ground should be previously deeply trenched and manured, so as to leave it in readiness to receive the plants directly they arrive from the nursery. It is most essential that soil shall be deeply worked for roses, especially if of a cold, retentive nature. It often happens that roses show signs of diminishing vigour after a few seasons; this can usually be accounted for either because the soil has become poor, or because the roots have reached unsuitable subsoil. By lifting such plants and trenching the soil, and adding a liberable quantity of farmyard manure and coarse bonemeal, they will readily respond when replanted.—T. B. Field, Wych Cross Place Gardens.

THE NATIONAL CHRYSANTHEMUM SOCIETY'S
GREAT AUTUMN SHOW
OF
CHRYSANTHEMUMS
will be held at the
CRYSTAL PALACE,
on NOVEMBER 5th, 6th, and 7th, 1913.
Write for Schedule (post free) to the Secretary,
Mr. RICHARD A. WITTY,
72, Savernake Road, Gospel Oak, N.W.
Admission to Palace (including Show), 1s.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

Despite the wet and dismal weather on Tuesday, October 21, there was a first-rate exhibition at the Royal Horticultural Hall, Westminster, and also a capital attendance. Dahlias, chrysanthemums, alpines, shrubs, fruits, and orchids provided the greater part of the display, and the first-named were of great excellence for so late in October. Novelties were not numerous, and no First-class Certificate was awarded, though the Orchid Committee granted six Awards of Merit, and the Floral Committee four.

CHRYSANTHEMUMS.

Mr. H. J. Jones, Ryecroft Nursery, put up a delightful exhibit of chrysanthemums, big blooms and singles being set up charmingly in stands and low bowls. In the back row the big blooms of Bob Pullen, Mrs. G. C. Kelly, Wiseman, Mrs. W. T. Smith, Mrs. J. Surry, Master Rex, and Joan Stratton were associated with tinted chestnut foliage and little sprays of the white Michaelmas daisy named Caterham Gem. This daisy was one of those final touches Mr. H. J. Jones is so fond of putting to his exhibits, and it was greatly admired as such. In the bowls we noted clean, fresh flowers of Sœur Melaine, Patricia, Arthur, Vick, Sonnie, Cranfordia, Mrs. Craigg, Mrs. Dorothy Weedon, and other good decorative and single varieties. Altogether a fine display, finely arranged. A capital group of dwarf-grown chrysanthemums from Messrs. H. B. May and Sons, Edmonton, contained good batches of Cranford Pink, Cranford Yellow, Julian Violet, Champ d'Or, and Cranfordia; heaths, bouvardias, and ferns completed the exhibit.

The chrysanthemums from Messrs. W. Wells and Co., Merstham, were greatly admired. Single, decorative, and big Japanese varieties were all represented. Among big sorts William Vert (A.M.), Mrs. G. Drabble, Mrs. R. Luxford, Queen Mary, and Mrs. David Syme were most conspicuous; while of singles, Caterham Bronze, A. J. Seabrook, Corrie Luxford, Kitty Riches, and Yellow Firebrand were most in evidence. Chrysanthemums were presented largely to view on this occasion. The Misses Price and Fyfe, Grove Park Nursery, Lee, contributed good stands of Rose o' the River, a bright single; the golden Cranfordia, H. W. Thorpe, Le Pactole, etc. From Messrs. J. Peed and Son, West Norwood, came a number of large Japanese blooms set in ferns in front of a background of singles, the latter including Joan Edwards, Queenie Jessop, Hilda Paice, Ceddie Mason, and autumn tints.

Mr. W. J. Godfrey, Exmouth, brought forward a number of large chrysanthemums, and an excellent selection of single and decorative varieties; of the singles Miss Mary Pope, Constance, Captivation, Attraction (fine scarlet, new), Mrs. Gilbert Phear (palest mauve), and the yellow Canary were capital.

DAHLIAS AND ROSES.

The bank of dahlias set up by Messrs. Carter Page and Co., London Wall, suggested early September, and was ample evidence of this kindly autumn; the flowers were clear and bright, and put up in abundance, cactus, collarette, single, pompon, and pæony-flowered sorts being alike well represented. Mr. Jas. B. Riding, Chingford, confined his attention chiefly to pæony-flowered and collarette varieties of dahlias, and of the latter he had a capital collection in a great variety of colouring, the brilliant General de Sonis standing out conspicuously.

Dahlias and hardy flowers shown by Messrs. Thos. S. Ware, Lim., Feltham, made a brave show of colour; the pæony-flowered dahlias were very fine, notably the varieties Mrs. George Gordon, Pennant, Empress, Germania, Flamingo, and Colonel Cody.

Mr. George Prince put up roses almost as gaily as if it were a July day; the flowers were fresh and fragrant, and there were quite good blooms of Hugh Dickson, Mrs. Herbert Stevens, La Tosca, Lyon Rose, Lady Hillingdon, and Frau Karl Druschki. The Rev. J. H. Pemberton, Havering, exhibited his three new roses, Moonlight, Danae, and Daphne; the two former we have very frequently referred to in terms of praise.

CARNATIONS AND GREENHOUSE PLANTS.

A bank of carnations, composed of White Swan and Mrs. Lucy Mackinnon varieties, formed the centre of a large group contributed by Messrs. Wm. Cutbush and Son, Highgate; the flanking portions consisted of Michaelmas daisies, and such carnations as Mrs. L. D. Fullerton, Mdme. Barrato, and Lady Ingestre. In another part of the hall this firm set up some splendid hydrangeas, the heads of René Gaillard being extra fine. Libonia Penrhosiensis was also very well shown, and dwarf roses were quite good.

The carnations from Messrs. Stuart Low and Co., Enfield, were well displayed, and the group included large bouquets and stands of Salmon King, Empire Day, Gorgeous, Salmon Robe, Sunstar, Enchantress, Supreme, and the useful Rosette. Carnations were admirably displayed by Messrs. Allwood Brothers, Wivelsfield, Haywards Heath; among new varieties we made note of Cinderella, Yellow Stone, Fairmount, Enchantress, Supreme, and Wivelsfield White, the latter of fine form and substance.

Some capital carnations, exhibited by Messrs. George Fairbairn and Sons, Botcherby, Carlisle, were of much interest to specialists. One named Cinderella, with scarlet flakes and shading on heliotrope, gained an A.M.; Trafalgar Day, deep scarlet, and Violetta were two other good varieties shown well by the Carlisle firm.

A bank of handsome greenhouse flowering plants from Messrs. Jas. Veitch and Sons, Chelsea, was composed of batches of dwarf chrysanthemums, the yellow Lindenbergia grandiflora, the rich blue Exacum macranthum, and the showy winter-flowering begonias Fascination, Mrs. Heal, Exquisite, Optima, and the wonderfully free-blooming rich carmine-pink Elatior.

Very bright were the pelargoniums staged in large bunches by Mr. A. H. Cole, Swanley, Kent. Messrs. Wills and Seegar, South Kensington, exhibited fine crotons, hydrangeas, Phœnix Roebelini, art bowls—some a very clever imitation of old bronze receptacles—bertolonias, and the pretty Erica gracilis.

HARDY FLOWERS.

A large and very attractive exhibit from Messrs. Dickson and Robinson, Manchester, received and deserved much admiration. This firm does not often come to Westminster, but when it does then a good exhibit is assured. Michaelmas daisies were delightful, and were all represented by single-stemmed plants, lifted, and with the roots bound up in damp canvas. The arrangement of the taller growers over the dwarf ones was capital, and here and there were large stands of decorative, pompon, collarette, and cactus dahlias and chrysanthemums, the latter being also used as a margin. A few particularly graceful small-flowered perennial asters were Virgin Queen, Approval, Maidenhood, Chastity, Delight, and Ringdove. These and other varieties of similar elegance made this display a particularly elegant and pleasing one. Lilium sulphureum, and the beautiful gladioli Afterglow, Peace, and Dawn were well shown by Messrs. Barr and Sons, Covent Garden, with other hardy flowers.

Fragrant violets from Mr. J. J. Kettle, Corfe Mullen, Wimborne, were a centre of interest for ladies, their size, colour, and sweetness attracting general attention. Marie Louise, Mrs. J. J. Kettle, Mrs. J. J. Astor, Kaiser Wilhelm (a very big single), Czar, Admiral Avellon, Princess of Wales, and La France were a few of the best in a first-rate collection. The Wargrave Plant Farm, The Arcade, Liverpool Street, contributed a large selection of early chrysanthemums, and associated them with coloured beech foliage; among lowly hardy plants exhibited by this firm Polygonum vaccinifolium corokia, cotoneaster, and Pratia begoniæfolia with dark purple berries were attractive species.

Gentiana acaulis, Nierembergia rivularis, saxifrages, and the quaint grey-leaved Matthiola fenestralis, with a few dwarf conifers, made up an interesting rock garden exhibit from Mr. Clarence Elliott, Six Hills, Stevenage. Messrs. Whitelegg and Page, Chislehurst, also displayed a little rock garden, and in it they had graceful hardy fuchsias, colchicums, the charming Potentilla Miss Willmott, Cheiranthus alpinus, mimuluses, sedums, and New Zealand veronicas.

TREES AND SHRUBS.

Messrs. J. Cheal and Son, Crawley, provided an interesting exhibit of sprays of trees and shrubs with autumn colouring and autumn berries. Maples, viburnums, oaks, hypericums, rhus, symphoricarpus, azaleas, and crataegus were capital, and a small collection of ceanothuses in full floral beauty added to the attractions of the group. Near by the same firm put up a collection of graceful conifers suitable for garden decoration and a small collection of clipped trees. Colutea cruenta, Desfontainea spinosa, Cytisus capitatus, nerines in variety, and colchicums were a few of the interesting things in a group put up by Mr. G. Reuthe, Keston, Kent.

Mr. L. R. Russell, Richmond, put up a very extensive display of bamboos and tree ivies across the top end of the hall, and brightened up the sombre hues of shrubs with clematis, hydrangeas, ceanothuses, lithospermums, hemamelis, etc.

ORCHIDS.

A fine specimen of Cypripedium picturatum, with five-and-twenty flowers, gained a Cultural Commendation for Mr. White, grower to Sir Trevor Lawrence, Bart., Dorking. Cattleya Empress Frederick var. Avid Clifton, from Pantia Ralli, Esq., of Ashtead Park, gained an A.M.; it is a lovely thing with white sepals and petals, and a gold, white, and soft purple lip. F. Wellesley, Esq., Woking, and C. J. Phillips, Esq., The Glebe, Sevenoaks, each showed several orchids, and the latter gained an A.M. for Cattleya graniris, red-brown and purplish-crimson. H. S. Godson, Esq., West Hill, Putney, showed several sophro-lælia and sophro-cattleya hybrids.

Mr. W. R. Lee, Plumpton Hall, Heywood, brought up a small collection of cypripediums, and his leading sorts were C. Royal Sovereign, C. Pallas Athene, C. Boltoni with four white flowers, and the bold C. Dreadnought, and C. Queen Alexandra (A.M.) Some very choice orchids exhibited by Mr. H. Alexander, orchid grower to Sir George Holford, Westonbirt, Gloucester, were greatly admired. Oncidium varicosum Westonbirt var. had particularly large golden flowers; Cattleya Fabia was good, and so were Lælio-cattleya Neleus, Cypripedium Boltoni, Odontoglossum Vivien, and the lovely Brasso-cattleya Mrs. J. Leemann var. Rajah.

Messrs. Sander and Sons, St. Albans, exhabited Cattleya Mantini in good form, C.

Mrs. Pitt, L.-c. Walter Gott, the charming little Pleione præcox, the strange Dendrobium Cœlogyne, and Cœlogyne fuliginosa maxima. Dendrobium Phalænopsis Schroderianum and Oncidium varicosum were finely shown by Messrs. Stuart Low and Co., Enfield; of the first-named they had a beautiful white form. Cattleya Gaskelliana alba and L.-c. Luminosa were other good things.

Cypripediums in variety, Cattleya Bowringiana, the bright Phaius-cymbidium Chardwarense, and Miltonia cuneata were among the chief orchids shown by Messrs. J. Cypher and Sons, Cheltenham. Messrs. Hassall and Co., Southgate, put up Cattleya Dusseldorfi Undine, varieties of C. labiata, C. aurea, and C. Hardyana.

Messrs. Armstrong and Brown, Tunbridge Wells, contributed Cattleya Acis, C. Venus, and C. Thyone, all yellow-flowered sorts; C. Mantini, Brasso-cattleya Maronæ, Cypripedium Gaston Bulteel, several odontiodes, and Cirrhopetalum fascinator. Sophro-lælio-cattleya Laconia, with deep old rose flowers and a ruby lip, gained an A.M. for Messrs. Charlesworth and Co., Haywards Heath; Cattleya Mantini and Lælio-cattleya Thyone were also finely shown by this firm. Mr. R. G. Thwaites, Streatham, and Messrs. Flory and Black, Longley, Slough, also showed a few orchids.

FRUITS AND VEGETABLES.

Apples were very finely shown by Messrs. Jas. Veitch and Sons, Chelsea, though in other years the fruit from the Longley Nursery has often been of higher colour. In size, cleanness, and other evidences of high culture the collection was excellent. Outstanding varieties among the hundred-and-ten sorts shown were Annie Elizabeth, Bow Hill Pippin, Cox's Pomona, Blenheim Pippin, Bramley's Seedling, Lane's Prince Albert, Blue Pearmain, Gascoyne's Scarlet, Edward VII., Christmas Pearmain, Chas. Ross, Bismarck, Beauty of Stoke, Emperor Alexander, Cox's Orange Pippin, and King of the Pippins. Apples were capitally grown by Messrs. H. Cannell and Sons, Swanley, this firm setting up grand fruits of Hollandbury, Striped Beauty, Lord Derby, Dumelow's Seedling, Peasgood's Nonsuch, Bramley's Seedling, Chelmsford Wonder, etc.

Mrs. Gordon Canning (gardener, Mr. H. Prentice), Hartpury House, Gloucester, presented an interesting collection of cider apples with photographs of trees of these varieties. There was also a collection of culinary and dessert apples and pears, representing about eighty-five varieties, and all the samples were of a high order of merit. Lord Derby, Severn Bank (a local variety), Warner's King, Annie Elizabeth, Hollandbury, Ribston Pippin (fine colour), and Newton Wonder were fine dishes. Four large citrons, some splendid pears, medlers, melons, and Muscat of Alexandria, Alicante, and Mrs. Pince grapes completed a large display from such a distant private garden.

An excellent display of vegetables was made by Messrs. Barr and Sons, Covent Garden, and it was as attractive as excellent. There were two hundred dishes representing about a hundred and fifty varieties, and about fifty kinds, besides splendid samples of all leading kinds, notably of celery, leeks, cauliflowers, and onions; there were aubergines, mushrooms, capsicums, winter radishes, celeriac, herbs, salsify, maize, kohl rabi, and late peas, beans, and marrows.

AWARDS OF MERIT.

To Chrysanthemum Mrs. R. C. Pulling, from Mr. H. J. Jones, Ryecroft Nursery, Lewisham; to Chrysanthemum William Vert, from Messrs. W. Wells and Co., Merstham; to Chrysanthemum Amy Poulton, from Mr. H. Poulton, Ware; to Carnation Cinderella, from Messrs. George Fairbairn and Son, Botcherby, Carlisle; to Cypripedium Queen Alexandra, from Mr. W. R. Lee, Plumpton Hall, Heywood; to Oncidium varicosum Westonbirt var., and to Odontoglossum Vivien, from Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury; to Sophro-lælio-cattleya Laconia, from Messrs. Charlesworth and Co., Haywards Heath; to Cattleya graniris, from Mr. C. J. Phillips, The Glebe, Sevenoaks; and to Cattleya Empress Frederick, from Pantia Ralli, Esq., Ashtead Park, Leatherhead.

MEDALS.

Gold.—To Messrs. Barr and Sons, Covent Garden, for vegetables; to Messrs. James Veitch and Sons, Chelsea, for apples.

Silver-gilt Banksian.—To Mr. H. Prentice, gardener to Mrs. Gordon Canning, Hartpury House, Gloucester, for dessert, culinary, and cider fruits; to Mr. L. R. Russell, Richmond, for shrubs; to Mr. H. J. Jones, Ryecroft Nursery, Lewisham, for chrysanthemums.

Silver Flora.—To Messrs. J. Cheal and Sons, Crawley, for shrubs, etc.; to Messrs. Wm. Cutbush and Son, Highgate, for hardy flowers and greenhouse plants; to Messrs. Dickson and Robinson, Manchester, for Michaelmas daisies, etc.; to Messrs. Stuart Low and Co., Enfield, for carnations; to Messrs. Carter Page and Co., London Wall, for dahlias; to Messrs. Jas. Veitch and Sons, Chelsea, for winter-flowering begonias, etc.; to Messrs. W. Wells and Co., Merstham, for chrysanthemums; and to Messrs. Armstrong and Brown, Tunbridge Wells, for orchids.

Silver Knightian.—To Messrs. H. Cannell and Sons, Eynsford, for hardy fruits.

Silver Banksian.—To Messrs. J. Cypher and Sons, Cheltenham, for orchids; to Mr. Alexander, grower to Sir George Holford, Westonbirt, Tetbury, for orchids; to Mr. W. R. Lee, Plumpton Hall, Heywood, for orchids; to Messrs. Hassall and Co., Southgate, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; to Messrs. Allwood Brothers, Haywards Heath, for carnations; to Messrs. H. B. May and Sons, Edmonton, for chrysanthemums, etc.; to Messrs. J. Peed and Sons, West Norwood, for chrysanthemums; to Mr. George Prince, Longworth, for roses; to Mr. J. B. Riding, Chingford, for dahlias; to Messrs. T. S. Ware, Lim., Feltham, for dahlias; and to the Wargrave Hardy Plant Farm, The Arcade, Liverpool Street, E.C., for chrysanthemums and alpines.

Bronze Banksian.—To Messrs. Barr and Sons, Covent Garden, for liliums and gladioli; to Mr. W. J. Godfrey, Exmouth, for chrysanthemums; to Messrs. Wills and Segar, South Kensington, for greenhouse plants.

SCIENTIFIC COMMITTEE.—October 7.

Present: Mr. E. A. Bowles, M.A., F.L.S. (in the chair); Messrs. G. Gordon, H. J. Elwes, W. C. Worsdell, R. Hooper Pearson, E. M. Holmes, J. Fraser, A. Worsley, F. J. Chittenden (hon. secretary), and C. R. Scrase-Dickins (visitor).

CYCAS REVOLUTA.—Mr. E. M. Holmes showed the ripe seed of Cycas revoluta. It had been grown and ripened in England.

UNCOMMON PLANTS.—Mr. H. J. Elwes showed a hippeastrum with green flowers, which, it had been suggested, was a hybrid between hymenocallis and a garden hippeastrum, two genera which have hitherto resisted efforts to cross them. It was, however, evidently Hippeastrum calyptratum, a species remarkable in the genus, not only for the curious growth which obstructs the throat of the perianth, but also from its evergreen habit.

TRICYRTIS STOLONIFERA, a plant which Mr. Elwes has found in bamboo jungles in Formosa, where it reaches a height of about 6in. only, while in England it grows 4ft. tall in gardens, still maintaining its underground creeping habit. Mr. Elwes also showed a lily which he had found growing in Formosa, where it flowered in March, bearing up to as many as forty flowers. It strongly resembled some of the forms of Lilium speciosum.

Mr. A. C. Bartholomew, of Park House, Reading, sent a number of interesting flowers, including Galanthus Olgæ, Gentiana Kurroo, Aspila buphthalmifolia, Solanum sisymbrifolium, Anchusa myosotidifolia, Malvastrum lateritium, and others.

AFRICAN FRUITS, ETC.—Mr. W. C. Worsdell exhibited fruits of a species of Eriodendron with its silky cotton-covered seeds, Areca nuts, and a leaf of mango from Zanzibar covered with scale insects, which he said was the usual condition there.

PELARGONIUM CITRIODORUM.—Mr. J. Fraser showed beautifully dried specimens of Pelargonium citriodorum and other forms from the Wisley collection, and commented upon the origin of these forms, mostly apparently from P. crispum. The results of Mr. Fraser's investigations will be published in the "Journal" of the society.

LINARIA HYBRID.—Mr. E. A. Bowles showed a Linaria which had appeared in his garden, and was possibly a hybrid between L. vulgaris and L. purpurea.

National Sweet Pea Society.

The annual general meeting of this society promised to be a most interesting one, and the members, to the number of nearly a hundred, who gathered at 2.30 p.m. at the Hotel Windsor, Westminster, on Monday, October 20, were not disappointed. Mr. Herbert Smith, chairman of committee, was voted to the chair, in the absence of the president, Sir Daniel Morris.

There were signs of coming excitement as soon as the minutes of the previous annual meeting had been read, when the Chairman pointed out that the recommendation of that meeting to the Committee relative to postal voting was not considered advisable, and if carried out would have been illegal. Captain Ashworth at once rose, and in very strong terms moved a vote of censure upon the Committee in the following terms: "The meeting expresses its regret that the General Committee failed to carry out the recommendation of the late general meeting to take a postal vote of all the members of the society upon modifications of rules that might be brought forward before the next general meeting." Needless to say this was rejected by a large majority, only three voting for it.

ANNUAL REPORT.

The annual report and financial statement for the year were then read by the hon. secretary. In the former it was made clear that climatic conditions were responsible for the failure of trials and outings. The exhibitions in London and Carlisle were both excellent, but the Committee evidently finds provincial shows expensive, and of little value in increasing membership. It was a pleasure to find that the dread question of "streak" disease is kept in mind by the Committee, and the offer of ten guineas and a gold medal to the first person who satisfies the Committee that a cure and preventive of this malady has been found should stimulate investigation. Membership has declined a little, or perhaps it would be better to say that a large number of subscriptions for 1913 remain unpaid. A sympathetic reference to the loss of Mr. Robert Sydenham, thanks to all helpers, and a notification of the London Show on July 16, 1914, and negotiations in progress for a provincial show at Belfast next year, concluded a most interesting and frank report.

Financially the Society had not done quite so well as usual this year. It had a turnover of £874 7s. 4d., but the balance carried forward is £23 8s. 10d, as against the one of £53 11s. 5d. brought forward from 1912. Outstanding subscriptions, Carlisle Show expenses and prizes, and the Viner Testimonial Fund, are answerable for this lessened balance to the good. Printing and stationery, necessarily a large item with a society that issues publications, came little short of £300, while over £50 for postages and telegrams show that the secretarial work is fairly heavy. The income from subscriptions came to £311 6s. 8d., as against £335 19s. 9d. in 1912. Some items of income are a little larger than usual,

and, on the whole, the Society is to be congratulated upon coming through such a busy year so well, for it has £200 on deposit, as well as many valuable effects.

The Chairman moved the adoption of the report and financial statement, and added a few lines to the former to the effect the Committee regretted that, for purely business reasons, Mr. C. H. Curtis was no longer able to continue as hon. secretary to the Society. Mr. Pearce seconded the motion, and it was carried unanimously.

Then followed votes of thanks to the retiring president and chairman, to committees, to treasurer, and to the hon. secretary. Many nice things were said about Mr. Curtis and his work for the Society since he became hon. secretary early in 1906, and to the thanks were added unanimously and with applause an honorarium of 70 guineas and the Gold Medal of the Society. There were expressions of regret that Mr. Curtis could no longer serve as secretary, and he himself pointed out that business matters alone prevented him from continuing to hold the position. The speakers to these various resolutions were Messrs. Gordon, Harrison, Harvey, Leak, Brunton, Bolton, W. P. Wright, Pinches, Want, and S. B. Dicks.

PROPOSED NEW RULES.

All these matters being disposed of, the Chairman, in answer to a question, said that Miss Hemus's proposed new rules should be taken en bloc. Captain Ashworth, on behalf of Miss Hemus, then moved that the proposed rules as circulated to members be adopted in supersession of those already existing. There appeared to be no seconder, and so Mr. H. J. Wright formally seconded the proposal so that it might receive consideration.

Mr. George Gordon, V.M.H., the first chairman and also the first president of the Society, pointed out the ignorance of society management evidenced by the proposals before the meeting. He averred that to block out traders altogether was foolish, as traders were as honest and honourable as other people, and he was especially severe upon proposed Rule 6, i.e., "That the business of the Society shall be conducted by a general committee consisting of the president, vice-president, treasurer, and twelve members. The whole of these must be persons who have never received money by the sale of sweet pea flowers, seeds, or plants, or for writing in connection with sweet peas, and who are not in any employment connected with the horticultural trade." Mr. Gordon expressed a hope that Miss Hemus's proposals would be rejected by an overwhelming majority because, if carried, they would inevitably mean the early end of the Society and its work.

Mr. Walter P. Wright waxed sarcastic, unnecessarily so, we thought, over the proposals. In his opinion the suggestion that subscriptions should be "payable on the anniversary of date of joining" was unworkable. Mr. J. S. Baker, while not approving of the proposals, hoped that those opposing them would do so with dignity. Mr. F. H. Chapman and Mr. G. W. Leak also spoke, and the motion was put, with the result that it was lost by 65 votes to 3.

On the motion of Mr. F. H. Chapman and Mr. T. Stevenson, thanks were accorded Captain Ashworth and Miss Hemus for the trouble they had taken in preparing and submitting proposals for new rules. It was pointed out that such thanks did not carry in any degree an endorsement of the proposals, or acquiescence in the unfortunate terms used concerning the committee when the members of the society were circularised by Miss Hemus.

Mr. S. B. Dicks drew attention to a printer's error in the proposed new rules for the regulation and conduct of the Floral Committee as submitted by Mr. W. P. Wright; he also asserted that these proposals, if adopted, could not become operative until the next annual general meeting, because they provided for nominations to be sent in "at least seven days before the annual general meeting." Mr. Dicks also called for a definition of an amateur, and the Chairman said that hitherto the committee had followed the R.H.S. definition. Mr. W. P. Wright said he was willing that his proposals should come into force at the next annual general meeting, and so eventually it was decided that his proposals should come up for consideration at a special general meeting, and if, or as, adopted, then they should become operative at the annual general meeting in October, 1914. A motion to this effect was carried by 42 against 14.

OFFICERS AND COMMITTEE FOR 1914.

A proposal to hold duplicate trials was defeated by the motion of Mr. F. J. Harrison and Mr. G. W. Leak, i.e., "That no second trials be held south of Burbage in 1914," which was carried unanimously. Mr. S. B. Dicks imported a little humour into these proceedings, and so the meeting was soon in good form for proceeding with the elections.

Mr. Hugh Dickson, of Messrs. Alex. Dickson and Sons, Newtownards and Belfast, was unanimously elected president for 1914; Mr. Edward Sherwood was re-elected hon. treasurer, and Mr. F. W. Harvey appointed chairman of committee for the ensuing year; Messrs. J. Collingridge, V. T. Hill, L. Perkis, Christy, and Bide moving the several resolutions. Mr. Gluyas was re-elected auditor of the Society's accounts.

The election of secretary occupied a good deal of time; there were four nominations, and these were Messrs. A. C. Bartlett, T. A. Weston, H. D. Tigwell, and Harry L. Foster. On the first ballot Mr. Tigwell led, and Messrs. Weston and Foster tied for second place; but, as Mr. Tigwell had not a majority of the votes cast, there was a second ballot, which left Mr. Weston and Mr. Tigwell in competition, and, curiously enough, these two tied with 39 votes each in the final ballot, and the chairman cast his deciding vote in favour of Mr. Tigwell. It was stated that the office would be a salaried one at £50 for the year 1914.

There were several resignations from the General Committee, and a few ineligibles. Those added to make up the thirty-six were Messrs. A. L. F. Cook, E. J. Gee, G. Herbert, J. S. Baker, A. Ireland, N. Thornton, F. C. Beale, C. H. Curtis, and W. H. Holloway; while Messrs. E. Cowdy (Ireland) and W. Cuthbertson (Scotland) were added to the list of corresponding provincial members of committee.

The scrutineers were Messrs. E. G. Quick, W. J. Stevens, and T. A. Weston, and they presently reported that Messrs. Thos. Jones, A. Ireland, T. Stevenson, R. Bolton, C. H. Curtis, Herbert Smith, G. W. Leak, A. Malcolm, and H. J. Wright had been elected by ballot to act as the Floral Committee in 1914.

A vote of thanks to the Chairman concluded the proceedings.

At the commencement of the conference proceedings it was announced that the General Committee had elected Messrs. R. Bolton, C. H. Curtis, H. J. Wright, T. Stevenson, A. Ireland, H. S. Bide, A. Hallam, H. Smith, G. W. Leak, J. S. Brunton, E. W. King, A. G. Stark, V. T. Hill, F. H. Chapman, and H. A. Perkis to act as the Executive Committee during 1914.

DINNER AND CONFERENCE.

About three dozen members dined together at 6 o'clock under the presidency of Mr. Hugh Dickson, who generously provided wines and cigars and cigarettes, and also subsequently provided fumigants for those who attended the conference. The only toasts were the loyal ones, "The Society," and "The New President."

A few minutes after 7 o'clock the President opened the conference proceedings by adverting to previous conferences, and the good they had done. He then called upon Mr. J. S. Brunton, who gave an admirable paper on "The Sweet Pea Industry." Mr. Brunton showed that the industry covered a wide field, and ranged from the raiser and grower down to the vase manufacturer, and the purveyors of special manures, flower pots, insecticides, etc. California, he said, produced about 665 tons of seeds per year, and one firm alone there had handled 134 tons of sweet peas. Germany and Holland chiefly provided seeds of grandiflora varieties. In 1903 one could purchase 1,200 seeds for 2s. 6d.; in 1913, 240 seeds for the same sum; the difference being due to the lower seed production of waved varieties. He referred to the great development of the cut flower trade in sweet peas in this country, both in the open and under glass, and stated that one firm alone had this year grown 25,000 disbudded plants, and for a long period cut 2,000 bunches of first-class flowers daily. £104 were realised in one week for 7,554 bunches of 12 spikes each of first-class flowers, and £94 for 19,792 bunches of ordinary blooms, and a larger number of spikes per bunches. The Edinburgh markets disposed of about £1,500 of sweet pea flowers in a season.

A firm near London made a speciality of sweet pea seedlings in pots, and used from 6 to 7 cwt. of seeds and 250,000 pots. In these and many other ways Mr. Brunton gave a most interesting and entertaining account of the industry.

A capital discussion followed, and, as a result, Mr. Brunton's remarks were amplified, but not one of his facts was questioned. Messrs. C. H. Curtis, H. Smith, V. T. Hill, T. Stevenson, T. A. Weston, G. Burt, A. Ireland, G. Drayson, T. W. Harvey, G. W. Leak, and Christy, took part in the proceedings, which were throughout carried on with great spirit. Mr. Ireland's advice as how best to secure a good crop of seeds will be long remembered. It was, "Pray, pray; but with a hoe in your hand." The desire that more attention should be paid to sweet peas for garden decoration was voiced in no uncertain manner, and made a considerable impression.

Mr. J. S. Brunton was heartily thanked for his lecture, and he in turned moved a vote of thanks to the President, which was accorded with great cordiality. And so ended a strenuous day and a somewhat critical one in the history of the Sweet Pea Society. We thoroughly endorse the closing sentence of the committee's report, i.e., "Hearty co-operation alone is needed to make the future of the Society as successful as its past.

ANSWERS TO CORRESPONDENTS.

SYMPHORICARPUS WITH COLOURED BERRIES.—E. A. S., Grantham: Your excellent illustration of the new Snowberry in the issue of October 11 leads me to ask whether any hardy members of the genus symphoricarpus has coloured berries. I shall be greatly obliged if you will answer this question as early as possible.—So far as we are aware, there is no symphoricarpus in cultivation with coloured berries. S. orbicularis, also known as S. vulgaris, bears the popular name of Coral Berry, but it has white fruits. Of this species there is a very pretty yellow variegated form named folius variegatis.

MARGUERITE MARILLAT PEAR. — R. T. H., Cobham: Please tell me whether Marguerite Marillat pear is a good variety to plant in a comparatively small garden. I have noticed this pear is frequently referred to in your pages in reports of exhibitions, and I believe the fruits attain a large size under high cultivation, but I fully understand that this does not necessarily mean the pear is a first-rate one for a small garden where only a few varieties can be accommodated.—This fine pear is a capital one for a small garden, as it crops freely and regularly; indeed, unless it is well fed, and some parts of the tree are occasionally pruned hard back to secure new and strong growths, this variety will crop so heavily that ere long the trees fail from exhaustion. It is a large September pear, of good flavour, and its season may be prolonged by picking some fruits early and placing them in a warm room, and by carefully storing the others; but it is in no sense a good keeping pear. Marguerite Marillat was raised about 1874 by a French nurseryman, near Lyons.

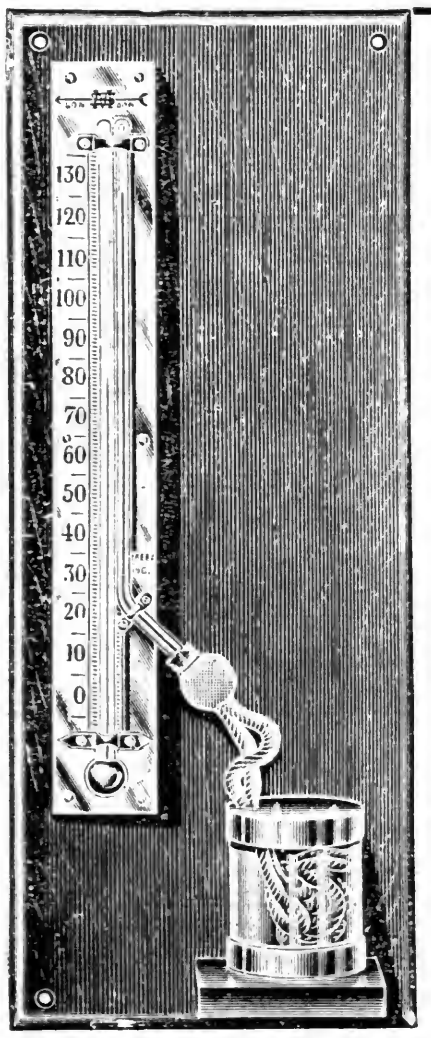
PROPAGATION OF NUTTALLIA CERASIFERA.—E. G., Cardiff: I have a good plant of Nuttallia cerasifera, and shall be glad if you will kindly tell me how best to propagate it.—The Californian Nuttallia cerasifera may be raised from imported seeds, or from cuttings of half-ripe growth inserted in sandy soil under a bell-glass or hand-light. Another method, and a good one, is that of carefully removing and transplanting sucker growths. Layering in autumn is also a good plan, and one we specially recommend you to try; choose one or two of the lower branches, and layer them in sandy soil.

EPIPHYTE AND PARASITE. — J. G., Carlisle: Please tell me the difference between an epiphyte and a parasite in the plant world.—An epiphyte is a plant which grows upon another plant, but does not draw its sustenance from the plant it grows upon. A very large number of orchids are epiphytes, as they grow upon tree stems and anchor themselves by gripping the bark with their roots. A parasite grows both on and in the plant which carries it, and draws all or part of its food supply therefrom. Two common instances of British plant parasites are to be found in the Dodder and the Mistletoe, but many fungi are also parasites.

STORING POTATOES IN CLAMPS. — F. S. L., Penrith: I have a larger quantity of potatoes than I can conveniently store in cellars, therefore I propose to clamp them. I have seen potatoes and swedes clamped in fields, and so have a general idea of the plan of procedure; but I should be glad if you will say what is the best method to follow. Select a site well-drained, and raised a little above the surrounding level, either naturally or artificially. On this place a thick layer of straw, and cover the estimated length and width. On the straw place the potatoes carefully, rejecting all that are damaged or in the slightest degree diseased, and building the rest up into the form of an inverted V. A little freshly-slaked lime strewn among the layers as the work proceeds has a sweetening influence, and is especially useful in a season when disease is prevalent. When all the potatoes are in position, cover them with a good layer of long straw, and then let the clamp remain for ten days or a fortnight, so that the steam caused by heating may escape. Meanwhile place a few planks over the straw to keep it safe from winds. When "heating," or "sweating," is finished, see that the potatoes are well covered with straw, and arrange so that a few good tufts of straw stand well above the ridge line, to act as ventilators after soiling. Cover the potatoes all over with about a foot of soil, made quite firm, and smooth on the outside. In very cold districts a further covering of mats or bracken may be necessary during especially severe weather.

SPAWNING A MUSHROOM BED. — T. D. C., Epworth: Kindly tell me at what temperature a mushroom bed should be spawned, how large the pieces of spawn should be when inserted, how deep they should be placed, and how far apart.—After a mushroom bed has been thoroughly well made up its temperature will rise for several days, and the cultivator must be on the watch for a decline in temperature. As soon as the declining temperature reaches 75 degrees at three inches below the surface, the bricks of spawn should be broken into about eight pieces, and such pieces should be inserted three inches deep and nine inches apart all over the surface of the bed. Casing or covering the mushroom bed should not take place until about a week after spawning.

DILL.—J. W. G., Rokeby: I have been asked to grow dill for use in the kitchen. I believe it is to be used for flavouring soups, but I have no knowledge whatever of the plant, and have never met with it in any garden in which I have been employed. Kindly tell me what dill is, and how it can be grown.—Dill is an annual herb now rarely asked for by cooks. It is quite easily grown in ordinary garden soil if seeds



The PREDICTOR.

AT A GLANCE

SIR HENRY CUNYNGHAME'S

FROST PREDICTOR

(PATENTED)

will tell you if the temperature of the air will fall below the freezing point.

No figures to consult nor levers to adjust. A glance at two thermometer tubes, arranged side by side, is all that is necessary. The **Predictor** also provides a very accurate thermometer, suitable for outdoor use.

XL-ALL XL-ALL X

Rust on 'Mums.

Mr. W. J. GODFREY, of Exmouth, one of our principal Raisers and Growers, writes as follows in his "Growers' Guide":—

"One grower of repute states that in striking his cuttings he utilised two large Cucumber pits. In one the "Black Fly" appeared, and to destroy these he used XL-ALL VAPORISER. The cuttings in this pit remained clean, in the other they were badly affected with the Rust. Another case which is worth observation:—Two houses, both containing plants coming into bloom, one was vaporised, the other not. In the first-named the disease made no progress, in the other it came very badly.

"It appears that camphor is used in the manufacture of XL-ALL COMPOUND (and who has not used it as a preventative of disease in their household?). This in the vapour condenses and remains on the foliage, and as a preventative of the Rust it may be worthy of further consideration."

Yes! it is true that camphor in a certain form does enter into the composition, and there is a SECRET SOMETHING ELSE in the manufacture which renders the original invention, XL-ALL, far superior to all imitations.

are sown thinly, in April, in shallow drills drawn a foot apart. Hoeing, watering, and subsequently thinning the seedlings to 9in. apart, will be all the attention needed. The leafage may be used green, or the plants may be pulled up when growth is finished, dried head downwards in an airy shed, and stored in bags until needed. Dill is the popular name of Anethum graveolens. If the herb is required as soon as possible in a green state, then sow a few seeds at intervals, in pots, and keep the plants in a warm greenhouse.

FERNS FOR AN OLD WALL.—R. L. B., Ruabon: I am proposing to utilise an old low wall for the purpose of a wall garden, and have a fairly good stock of small-growing and suitable plants for the work, with the exception of ferns. My better-half would like me to plant some ferns in the semi-shaded part of the wall, but as I am an amateur who has only taken up gardening as a hobby in recent years I am at a loss to know the best ferns for the situation at command. Your help will greatly oblige.—Suitable ferns for planting in old walls are Asplenium adiantum-nigrum, A. fontanum, A. germanicum, A. lanceolatum, A. ruta-muraria, A. trichomanes, and A. viride, Ceterach officinarum, and both Polypodium vulgare and Scolopendrium vulgare and their varieties. In favoured districts, and in a moist, shaded position, the graceful little Cystopteris fragilis is worth a trial, but it would be useless to plant it in a dry, sunny place. Similarly, in a warm, moist, shady spot, the beautiful Adiantum capillus-veneris would be available, but for the present you had better not include these two last-named species, merely bearing them in mind for future trial.

NAMES OF PLANTS.

J. S., Louth.—Euonymus europæus.

R. F., Taunton.—1, Melianthus major; 2, Aralia chinensis.

E. O. G., Chesham.—1, Sedum spectabile; 2, Aster diffusus horizontalis.

A. C. C., Uppingham.—1, Solidago rigida; 2, Odontoglossum crispum, poor form.

M. W., Bath.—1, Lonicera japonica aureo-reticulata; 2, probably Amelanchier canadensis.

F. L. D., Melton Mowbray.—1, Fraxinus ornus; 2, Helianthemum vulgare; 3, Verbena venosa.

C. T., Sidmouth.—1, Skimmia japonica; 2, Pittosporum Tobira; 3, Choisya ternata; 4, send when in flower; 5, Aster Tradescanti.

B. S. W., Caversham.—1, Erica gracilis; 2, Saxifraga oppositifolia; 3, S. Geum; 4, Leiophyllum buxifolium; 5, Arbutus Unedo.

NAMES OF FRUITS.

V. S., Brecon.—Alfriston.

S. S., Lewes.—1, Grenadier; 2, Cox's Orange Pippin.

T. O. B., Northallerton.—1, Pott's Seedling; 2, Mère de Ménage; 3, Lord Derby.

A. M., Bideford.—1, Newton Wonder, a fine fruit; 2, Washington; 3, Gascoyne's Scarlet.

E. P. G., Leicester.—1, Warner's King; 2, Stirling Castle; 3, Claygate Pearmain; 4, Cox's Pomona.

L. T. H., Chislehurst. — 1, Bismarck; 2, Hibston Pippin; 3, Dutch Mignonne; 4, Peasgood's Nonsuch.

H. N., Fareham.—1, Golden Noble; 2, fine fruit; 2, Washington; 3, Gascoyne's 4, probably a Chaumontel.

M. C. P., Streatley.—1, Bramley's Seedling; 2, Emperor Alexander; 3, not in character, probably Lady Henniker; 4, a small King of the Pippins; 5, Gravenstein; 6, Lane's Prince Albert.

GARDENING ENGAGEMENT.

In a recent issue we published a portrait of Mr. James Jeffrey, gardener at St. Mary's Isle, Kirkcudbright, and in the accompanying note it was mentioned that one of his sons, Mr. James Jeffrey, jun., was gardener to the Earl of Ancaster, at Drummond Castle, Perthshire. We now understand that Mr. Jeffrey, jun., has been appointed gardener to the Earl of Lonsdale, at Lowther Castle, Westmorland, one of the most important gardening appointments in the country. Mr. Jeffrey succeeds Mr. F. Clarke, who has been in charge at Lowther Castle for a long time, and who has done so much to render it one of the finest of the gardens in the North. He takes up his duties in December, we understand.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

MONDAY, October 27.—National Chrysanthemum Society; Floral Committee, at Essex Hall, Strand, at 3 o'clock; Executive Committee, at Carr's Restaurant, at 7 p.m.

TUESDAY, October 28.—Southampton Chrysanthemum Show; two days.

WEDNESDAY, October 29.—Kent County Chrysanthemum Society; two days.

Croydon Chrysanthemum Show; two days.

THURSDAY, October 30.—Torquay Chrysanthemum Show.

Elstree Horticultural Society; Lecture by Mr. George Gordon, V.M.H., on "Garden Roses," 7.45 p.m.

Maidenhead Chrysanthemum Show.

Weston-super-Mare Chrysanthemum Show.

FRIDAY, October 31.—Enfield Highway Chrysanthemum Society.

SATURDAY, November 1.—French Horticultural Society of London.

CATALOGUES RECEIVED.

S. MILLER, NEWPORT, ISLE OF WIGHT.—Mr. Miller offers sweet pea seeds in a quite novel fashion; by means of a grading machine he has produced three grades of seeds, i.e., largest and finest, medium, and smallest. An interesting list.

GEORGE BUNYARD AND CO., LIM., MAIDSTONE.—This catalogue of fruit trees and roses contains such admirable descriptions, historical notes, selections of fruits, and "monthly reminders," that it deserves a place on every gardener's bookshelf. The same firm sends a catalogue of hardy flowers and aquatics.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Spore Pods.

Undoubtedly one of the most interesting objects in connection with ferns is the sporangium or receptacle in which the spores are contained. In flowering plants, as we know, the vessels containing the seeds vary immensely in their construction, and are replete with all sorts of contrivances to scatter the seeds when they are ripe; while in some cases, as, for example, the dandelion, among many others, no containing vessel proper appears, but the seeds are inserted into a disc, after the manner of pins in a pincushion, and are eventually liberated by the wind acting upon the feathery attachments destined to carry the seeds far and wide at the proper time. In the case of the ferns, on the other hand, however greatly they may vary in other respects, the spore capsule is, as a rule, of one particular type, and among our native ferns, with the exception of the Adders-tongue, Moonwort, and Royal Fern, they are practically all alike. The popular notion is that the fine dust, usually brown, which is seen in patches dots or lines on the backs of the fronds is the spores themselves, but this is by no means the case. Fine as it is, it consists of nearly round or oval pods or sporangia, attached by short stalks to the veins of the frond, and, small as these are, each contains a considerable number of spores—some scores, in fact. This, of course, means that the number of spores is far larger than that of the pods themselves, though these may number thousands, and even hundreds of thousands, on a fair-sized, fertile frond. These pods or sporangia are little marvels of contrivance despite their minuteness. Under a microscope they are seen to consist of an oval receptacle, of, as a rule, a lucent brown colour. They are borne singly on a ribbed stalk, and the ribbing continues forming a projecting ridge from the point of attachment right over the top of the capsule and halfway down the other side, giving it somewhat the appearance of a fireman's helmet. It is this ribbed ridge which, when the spores are ripe and ready for scattering, begins to contract in length. It thus exercises a greater and greater strain upon the capsule, until at last a rupture occurs at the point where the ridge ends—i.e., halfway down the front, so to speak, of the helmet. The split so caused gradually widens, and the top half gradually lifts and bends backwards. At first this occurs slowly, but when the pod is split nearly in two, and gaping widely, the top half quite suddenly springs backwards, and in so doing jerks the contained spores far and wide in all directions, like a shrapnel shell. Anyone possessing a microscope of moderate power can easily watch and verify this performance by scraping off a few of the dust-like pods on to a glass slip, and inspecting them in a warm room, so as to hasten the drying, which brings about the shrinkage in question. At first the little heap is quite quiescent, but in a minute or two a sort of twitching sets in, marking the time of the initial split. The twitching increases, until the whole mass is on the move, and then suddenly, and quite unexpectedly to the novice, the mass will fly asunder, leaving gaps on the clear glass, into which gaps, as the capsules around follow such rapidly, there will be noted a little hailstorm of the spores themselves falling, with the accompaniment of the burst and now empty capsules, which are themselves jerked in all directions by the force of their own explosion. Such an experiment should, of course, be made fairly early in the season, before the capsules have already exploded, but as these ripen at different times, it is usually easy to obtain the necessary material at any time in the later growing season. To those who sow spores, this little experiment teaches a valuable lesson regarding the necessity of thin sowing, since it becomes quite clear how numerous the spores are; and that, as each one will require a space as large as a herring-scale for proper development of the prothallus, which precedes the fern proper, thick sowing must handicap this terribly by the resulting overcrowding.

MR. HUGH DICKSON,
President of the National Sweet Pea Society for 1913-14.

Mr. Hugh Dickson.—One of the most popular as well as one of the keenest of men in the seed and bulb trade, it is fitting that Mr. Hugh Dickson should have been chosen to be the President of the National Sweet Pea Society for the year ensuing. A great lover of sweet peas, he has, however, little sentiment concerning them, and his own novelties, as well as the novelties of others, have to give way promptly when a better variety of the same class appears. Although a son of Mr. George Dickson, and therefore a member of the firm of Messrs. Alex. Dickson and Sons, Newtownards, co. Down, Ireland, Mr. Hugh Dickson takes practically no part whatever in this firm's great business as rosarians. For many years he has devoted his abundant energy, splendid business ability, a fine memory, and his native Irish wit also, to the organisation of the firm's seed and bulb department, with headquarters at Royal Avenue, Belfast. In a very wonderful way he has made this department his life's work, and it is now regarded as one of the best-managed businesses of its kind in the United Kingdom. Mr. Hugh Dickson travels frequently in Great Britain and Ireland, and on the Continent, keeping a close watch upon the seed crops grown for him. He has also visited America, and adapted the brisk methods of the United States to British needs and ways. In business he is a man of few

words, but his words are weighty ones; in public life he does not shine because he hates the lime-light, and it was only after some pressure from his personal, trade, and amateur friends, that he accepted nomination for the N.S.P.'s presidency; in private life he is one of the kindest, jolliest, and most generous of men, and those who can count him as one of their friends feel they are thereby honoured. Mr. Hugh Dickson has a peculiarly intimate knowledge of bulbs, and has done much to foster the industry of bulb culture in Ireland, particularly in connection with late-flowering tulips. We wish Mr. Hugh Dickson every success in his presidential year.

Mr. J. Gurney Fowler, treasurer of the Royal Horticultural Society, and chairman of the R.H.S. Orchid Committee, has now removed from The Glebelands, South Woodford, to his new residence, Braekenhurst, at Pembury, near Tunbridge Wells. The new orchid houses are now ready, and will soon receive the famous Glebelands collection. We understand that Mr. Fowler has also built a house specially for the cultivation of sweet peas under glass.

A 75-Guinea Cup for Fragrant Roses.—Messrs. Clay and Son have presented to the Council of the Royal Horticultural Society a silver-gilt cup, of the value of £75, for annual competition (open to all) at the Holland House Show, its object being to endeavour to obtain a new race of roses of both good form and colour, but, "above all else, possessing the true old genuine rose scent, such as may be found in the old Cabbage or Provence rose, in General Jacqueminot, Marie Baumann, Duke of Wellington, General McArthur, etc." The distinct scent, known as "tea rose," is not, for the purpose of this competition, to be accounted as the "true rose scent." Not more than three different varieties may be shown by any one competitor, but at least three, and not more than six, cut blooms of each variety must be staged. For five consecutive years Messrs. Clay and Son will also present a smaller commemorative cup, which the Council will give to the winner of the challenge cup, when, at the end of the 12 months, it shall have been returned safely and in good condition. The winner of one year may not win again the next year, but only in alternate years. In any year the awarding of the cup may be withheld if the Council are of opinion that there is no exhibit worthy of it.

Edinburgh Royal Botanic Garden Guild. — The annual general meeting of this newly-formed guild will be held at the Royal British Hotel, Princes Street, on Friday, November 14, at 6.45 p.m., followed by a dinner at 7.15 p.m., with Mr. W. W. Smith, M.A., Assistant Keeper, in the chair. It is hoped by the executive that as many past members as possible will endeavour to be present, this being the first dinner held under the auspices of the guild.

The King's Contribution to the People's Palace Show.—In July last his Majesty entertained the People's Palace Horticultural Society at Windsor, and he has shown such interest in the working of the society that he sent an exhibit of fruit and flowers to the Chrysanthemum Show, held at the People's Palace, Mile End Road, Stepney, this week. Under the secretaryship of the Messrs. West, father and son, this society does excellent work, and its meetings, held on Saturday evenings, are largely attended. Last Saturday, when Mr. C. H. Curtis gave a lecture on "Bulbs," the large audience was composed of many grades of society, from the humblest of East-end artisans, to shopkeepers, merchants, busy City men, and clergymen, and there were a number of ladies present.

"**Botanical Magazine.**" — The plants figured in the current issue of this publication comprise Rhododendron hæmatocheilum, a Chinese species, bearing medium-sized flowers, deep red in process of development, and bright carmine when fully expanded. Nautilocalyx pallidus, a distinct species, a native of Peru, and thriving under warm greenhouse treatment; the flowers are creamy-white with purple streaks on the exterior of the tube. Schizophragma hydrangeoides is a climbing shrub, of Japanese origin, with cream-coloured flowers, that "bears the name which is familiar in English gardens, where it has for a couple of generations been erroneously applied to Hydrangea petiolaris, Sieb. and Znec, another and an allied Japanese shrub." The species is a comparatively recent introduction to British gardens, and first flowered in the gardens of Grayswood, Haslemere. Streptocarpus cyaneus, a beautiful species, closely allied to the well-known S. Rexi. The species is a native of Swaziland, and the flowers of the seedlings raised at Kew range from pale lavender to rose-mauve. Also Stanhopea grandiflora, which is re-referred to elsewhere.

Chrysanthemums at Essex Hall. — The members of the National Chrysanthemum Society's Floral Committee had a busy time at Essex Hall, Strand, W.C., on Monday last, as no fewer than thirty-five varieties of the Autumn Queen were brought up for judgment, ten being Japanese and twenty-five single varieties. The committee granted eight First-Class Certificates and five Commendations.

Trees for Dublin Streets.—No small interest attaches to the notification that Messrs. Sheppard and Son, landscape gardeners, of Dublin, have secured the contract for planting trees on the South Circular Road, in the Irish Capital. Archbishop Walsh pointed the way some time ago, when, after taking up residence at Drumeondra, he improved the adjacent public road by planting plane trees on the sloping banks. The municipal authorities followed up this good work by planting trees in neighbouring thoroughfares, and now the South Circular Road is to be planted. Further, it is believed that trees will soon be planted in the artisan district, notably in Ross Road, Bride Street, and Nicholas Street. It is with great pleasure we learn of this progressive spirit in a city which has long been renowned, both horticulturally and botanically.

York Gala, 1914.—Our York friends take time by the forelock, and their schedule of prizes to be offered at the gala on June 17, 18, and 19 is already to hand. The classes are as skilfully arranged as ever, and prizes are offered on a very liberal basis. We notice that Lord Deramore, the President, will give the first prize of £10 in a new class for a group of tuberons begonias, arranged on a space of 100 square feet. Other new and important features are classes for a group of rhododendrons in bloom, 200 square feet allowed; the best pair of hanging baskets, 24 inches in diameter; a circular, oval, or diamond-shaped group of bedding plants, 150 square feet, to be arranged in the centre of the tent; a semi-circular or corner group of bedding plants; and a trade class for eighteen bunches of sweet peas. In the already famous hardy plant and water garden class we find that no digging will be permitted, and exhibitors must arrange for a natural effect upon the ground level. In most of the group classes, there is a specification to the effect that the groups must front all ways, and suggested designs for the exhibits will be sent to exhibitors immediately their entry is received. Prospective competitors should at once apply for a copy of this new schedule to Mr. Fred Arey, Davyhall Chambers, Davygate, York.

The Crystal Palace. — The purchase of the Crystal Palace and grounds for the public use is proving a difficult undertaking. The Camberwell Borough Council decided a few days ago to contribute £600 towards the purchase money, instead of £15,000. Penge District Council, which promised £20,000, have withdrawn that offer, and agreed to contribute £5,000.

Exeter Guildhall and the Gardeners.—For twenty-one years the members of the Devon and Exeter Gardeners' Association have held their meetings in the Guildhall of the county capital, as a result of the kindness of succeeding mayors. Now, however, they have had to seek new quarters at the Oddfellows' Hall, Catherine Street, because the present mayor has decided that the Guildhall is the property of the City, and was intended for meetings of great public interest. We, in our simplicity, have always considered that agriculture and horticulture were of great public interest; and greater than we have proved that these crafts and sciences are of fundamental interest to the nation. We believe the Exeter Society will flourish in its new quarters, and be a power for good long after the present mayor has passed on.

Nomenclature of Stanhopea grandiflora.—The figure of Stanhopea grandiflora, and the accompanying letterpress, which appears in the current issue of the "Botanical Magazine," are of much interest as illustrative of some of the difficulties of the nomenclature of plants. Stanhopea grandiflora is one of the earliest known species of the genus, and was originally described and figured by Humboldt and Bonpland in 1805, as Epidendrum grandiflorum. Subsequently it was transferred by Kunth to Anguloa, and later it was referred to its true genus as S. grandiflora by Reichenbach. In the meantime Lindley applied the name S. grandiflora to a quite different plant, now regarded as a form of the earlier S. eburnea, Lindl., and Reichenbach reduced to the true S. grandiflora the Mexican species S. Buchepalus Lindl., and added to it, as a variety, the Panama species S. Jenischiana, Kramer. Later Lindley transferred the synonyms from the Eenador species to S. insignis, Frost, and thereby further increased the difficulties associated with the nomenclature of the species. We are further informed that the late Mr. Consul Lehmann during a visit to Cuenca, was able to collect there further material of S. grandiflora, which enabled Mr. Rolfe, in the "Orchid Review," to disentangle the history of the species.

More Scottish Botanists Needed.—Professor G. F. Scott Elliot, who is delivering a course of lectures before the Royal Technical College Botanical Society at Glasgow, is reported to have stated that "Botany was intended to benefit, not a particular coterie of students, but the whole civilised world. Scotland would require shortly clear-headed and plain-speaking botanists more urgently than at any other period, and as many as could be produced."

KENT COMMERCIAL FRUIT SHOW.

The third annual show of the Association of Kent Fruit Growers was held in the Corn Exchange, Maidstone, on Tuesday and Wednesday, October 28 and 29, and it was successful and very encouraging. As an exhibition, it differed widely from those of the usual horticultural societies, there being no attempt at artistic effect or decorative arrangement. The whole energies of the society are devoted to plain utility and stern commercial requirements. Thus the receptacles used were plain deal boxes of uniform size, lined with blue paper, and careful and sensible packing was estimated as a most important feature. Spectacularly the show would have been wonderfully attractive had the fruit been set up on dishes or baskets with decorations of flowers and foliage; but that is not the purpose of the Kent growers, and the animated conversation between exhibitors and judges turned on the respective merits of the various styles of packing demonstrated. The show afforded interesting and valuable evidence of the strides made in British fruit culture.

All through the fruit was of splendid quality, and it was apparent to all that our growers are realising the importance of careful grading, packing, and system, as well as good cultivation, of the most useful and prolific varieties. The association is doing good work, and we watch its progress with much gratification, since it is of direct benefit to what is now an important industry that will undoubtedly increase in extent and value to the community.

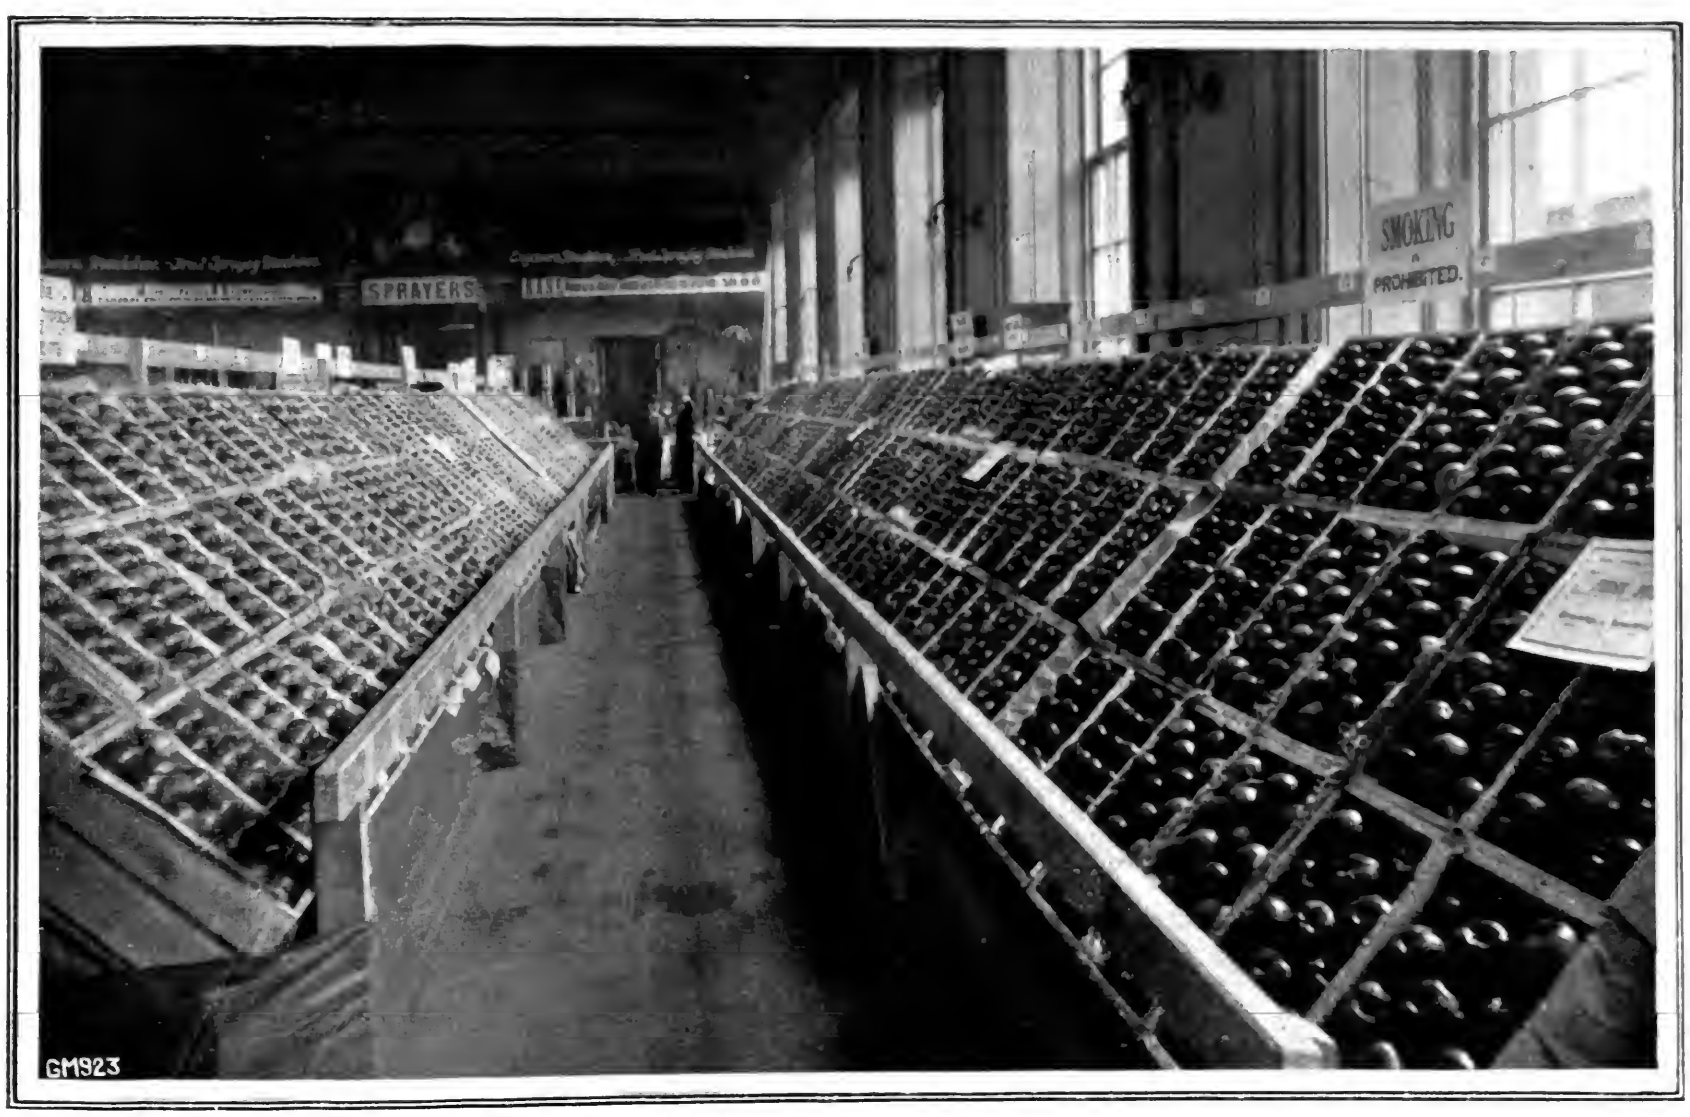
The schedule opened with a class for six boxes of Bramley's Seedling, and, as showing the high esteem in which this apple is held by commercial growers, it is worthy of note that no less than forty entries were forthcoming. The first prize was secured by Mr. S. Skelton, West Farleigh, Maidstone, whose apples were of great size, even, and well finished. The method of packing was what is technically termed "one-two-flat." This is done by placing a row of apples on either side of the box, with one fruit in the centre between two couples. The boxes contained three layers with fourteen fruits each, the approximate weight per box being forty pounds. Mr. G. E. Champion, Linton, Maidstone, came second, showing fruit of the scarlet form of Bramley's, which were more attractive in appearance than the green fruits. They were not, however, so large, there being twenty-one fruits in a layer. They were "square" packed, a method which admits of closer packing, but entails more risk of damage by bruising than the diagonal method. W. W. Hubble, Esq., Hunton, Maidstone, secured third prize. The boxes in this case appeared to be rather too full, albeit a slight bulge on the lid is an advantage rather than otherwise. Mr. O. Ellis, Bramley, Surrey came fourth. It must be added that many exhibits of superb quality had to go cardless, so keen was the competition in this remarkable class.

Six boxes of Newton Wonder, another very popular apple, made an excellent class of twenty-six entries, and throughout the whole number the quality and colour of the fruit merited high praise. F. Smith, Esq., Loddington, Maidstone, secured the leading award, and it would be difficult to find a finer lot of fruit carrying such rich colour, and capitally packed in two-two check pattern. The apples are in this style of packing arranged in twos alternately to left and right of the box, the cheek of the apple being exposed to view. Mr. A. Miskin, Chart Sutton, Maidstone, came second with a very nice lot of fruit packed in same style as the first prize exhibit. Mr. A. J. Carter, Billingshurst, Sussex, took third prize, his fruit being extraordinarily deep crimson in colour, but not over-large. Fourth prize was secured by S. Skelton, Esq., for a nice, serviceable lot of fruit, packed square-check pattern.

Lane's Prince Albert mustered twenty-nine entries, and, whilst quality was of a high standard, it was remarkable how widely the variety differed in colour and form in exhibits from various localities. A. Miskin, Esq., Chart Sutton, secured first prize, and his fruits were certainly a beautiful lot. They were square-cheeked packed, and, although this method shows off the apples to best advantage, there was a good deal of comment on the part of growers to the effect that the system makes bruising unavoidable. S. Smith, Esq., Barming, Maidstone, took second place, his fruit being of fair size, beautifully even, and packed eye upwards two-two pattern. Third prize went to E. B. Burns, Esq., East Farleigh, Maidstone, who had typical fruit packed two-three check pattern. A. J. Carter, Esq., Billingshurst, Sussex, showed bright red, showy fruits, scarcely recognisable as Prince Albert, but nevertheless an exhibit of high quality, fourth prize being awarded.

Blenheim Orange, still a grand and indispensable apple, did not form so large a class as might have been expected, but the nineteen entries staged were splendid examples, and were a centre of attraction to visitors. Messrs. Gaskain and Whiting, Dargate, Faversham, took first prize with a grand half-dozen boxes, every fruit being of large size, beautifully modelled, and rich in colour. The system of packing was square-check, but even if that should be criticised the quality of the fruit was beyond reproach. Second prize was secured by Messrs. W. Skinner and Sons, Boughton, Monchelsea, their fruits being large but not so even. W. W. Hubble, Esq., came third with a good exhibit packed three-four check.

Some immense fruits were shown in the class for six boxes of Lord Derby, an apple excellent for cooking, and remarkable for its size, but not at all a pretty one. Messrs. Gaskain and Whiting were again the success-



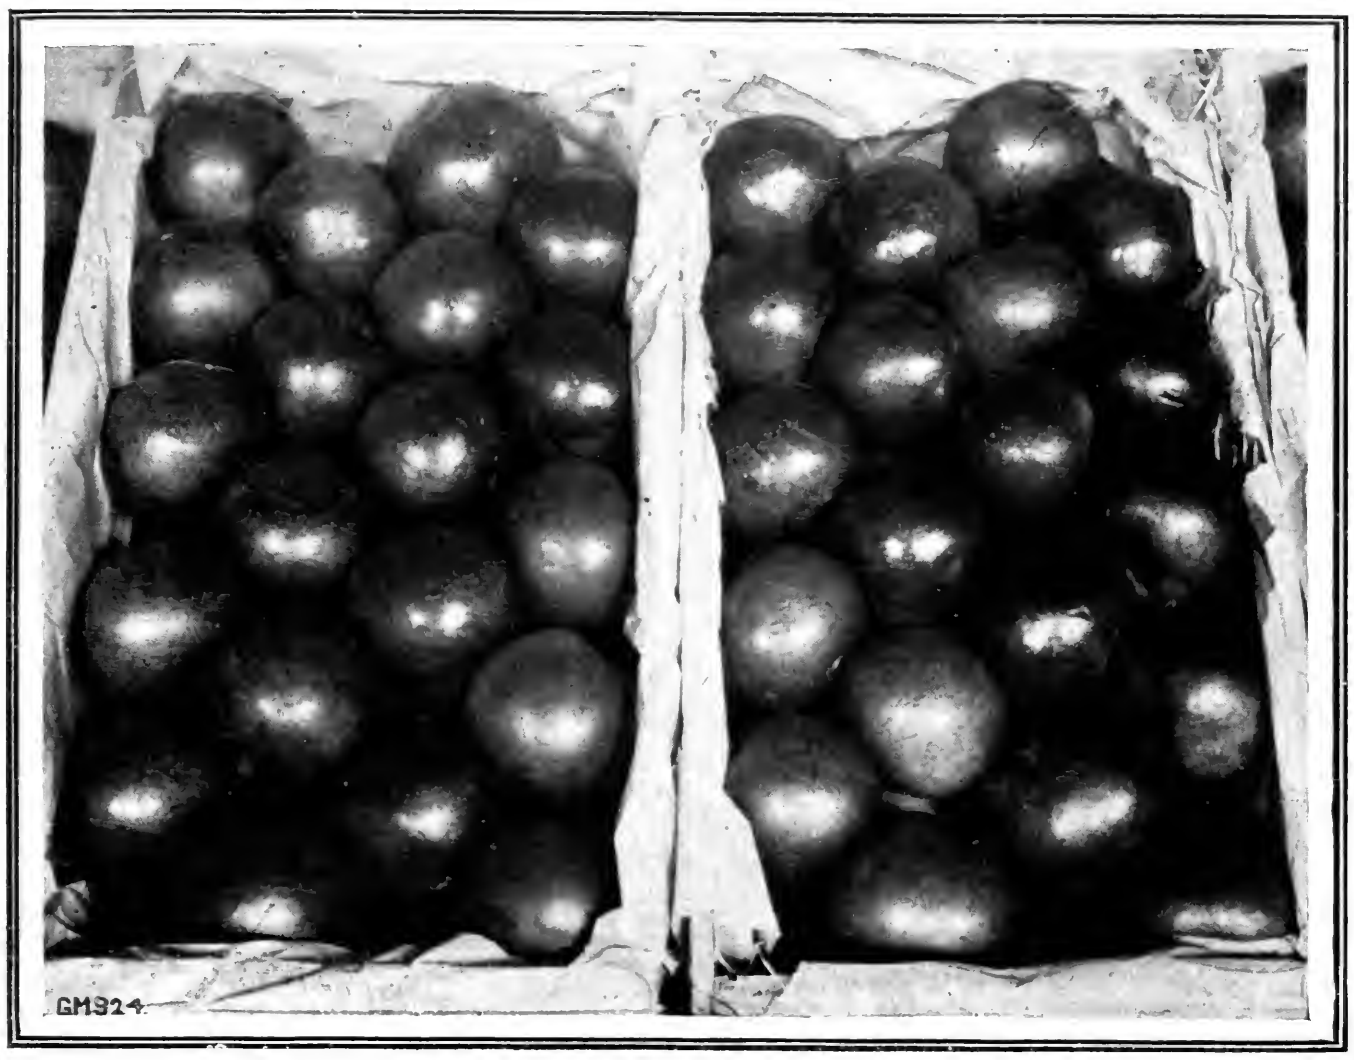
KENT COMMERCIAL FRUIT SHOW.

View showing Bramley's Seedling Apples; first prize exhibit on the extreme right.

ful exhibitors, their fruit being so large that only three dozen were required to fill each box. A. Miskin, Esq., was second prize-winner with a fine sample, and another exhibit by the same gentleman would have received third prize but for a rule prohibiting two prizes in a class going to one exhibitor. Messrs. G. Mount and Sons, Lim., Bekesbourne, Canterbury, received fourth prize with remarkably bright-coloured fruit of good weight.

The bright colour and pleasing appearance of the Worcester Pearmains attracted all but the regular growers who are familiar with this very pretty apple. That the variety is not quite so good as it looks may be gathered from the fact that only about a dozen exhibitors staged in the three boxes class. S. Smith, Esq., was first prize-winner; Messrs. G. Mount and Sons, Lim., and Messrs. Wakeley Bros., Lim., Rainham, Kent, taking second and third prizes in the order named. The apples from the last-named were very highly coloured.

Allington Pippin had a class for three boxes, and some twenty-six entries were staged. Some of the fruits were of wonderful size, and, in our opinion, much larger than is desirable. The first prize was awarded to H. M. Cobb, Esq., Higham, Rochester, who had large, but very even and pleasing coloured fruits. They were square-check packed, and were so well graded that every apple fitted exactly its position. Colonel J. T. Honeyball, Teynham, Sittingbourne, was second prize-winner, his fruit being very typical of the variety, and well packed on two-three pattern. The third prize exhibit, from H. G. Kleinwort, Esq., Boughton, Monchelsea, was not at all characteristic of the variety, although the small, smooth, yellow fruits were pretty and inviting. Seventeen entries of Cox's Orange Pippin (three boxes) did not form so fine a class as that of last year, but the first prize and champion cup exhibit, shown by Messrs. Gaskain and Whiting, was exceptionally good. Second prize went to W. D. English, Esq., Rochester, who showed beautiful, even fruit; third prize going to G. Hilder, Esq., Rolvenden, Tenterden.



KENT COMMERCIAL FRUIT SHOW.

First prize six boxes of Newton Wonder apples, showing style of packing adopted.

Three boxes of any dessert apple not specially provided for brought several exhibits of King of the Pippins, and a few of Charles Ross, King's Acre Pippin, and Beaumann's Red Winter Reinette. The last-named variety, shown by A. Miskin, Esq., secured first prize, and the fruits were a very creditable lot; second prize went to Messrs. Gaskain and Whiting, and Mr. A. J. Carter, Billinghurst, Maidstone, secured third prize for beautiful examples of King of the Pippins.

There were good entries for any unclassified culinary variety, Messrs. Gaskain and Whiting taking the leading award, and reserve for championship, with three boxes of Annie Elizabeth, very much resembling Newton Wonder in appearance. The examples shown were grand specimens. Quite a number of classes were provided for growers in Kent, and there were also classes for the best packed boxes, and for varieties raised within recent years; but the most important matter for us to record is that the show proved that British growers can grow and despatch to all parts of the Kingdom, as well as abroad, fruit of unsurpassable quality.

More characteristic of the usual horticultural shows were the exhibits staged by Messrs. G. Bunyard and Co., Lim., Maidstone, and Messrs. Seabrook and Sons, Chelmsford. The former had a long table on which dishes and baskets of picked fruits were shown in quantity. About 76 sorts of apples were shown, and every one was a variety of distinct merit, well worth attention. It it not necessary to single out special sorts for mention, but it must be said that every dish and basket was filled with splendid fruit; and, so far as arrangement is concerned, those who staged merit our congratulations. On Messrs. Seabrook's stand there were pyramids of The Queen, Bismarck, Royal Jubilee, Lane's Prince Albert, and other culinary varieties, as well as the more popular of the dessert apples. It was a most interesting and educative exhibit.

(Continued on page 832.)

SOME OF THE NEWER FRUITS.

Although several new varieties of apples and other kinds of fruit are annually placed before the Royal Horticultural Society's Fruit Committee, it is only those possessing some special merit that receive notice, and before an award is given the trees, in full fruit, have to be inspected by some of the members of that body and reported upon at one of the meetings. But no matter how good any of these new fruits may be, several years must elapse ere a good stock is worked up and grown into large fruiting trees, and this is probably why, to a great extent, we hear so little of some that have received awards during the past few seasons; but as time goes along these will no doubt, become as popular, if not more so, than many which have been in cultivation for many years.

Dessert Apples.

Going back so far as 1897 we have the variety James Grieve, which, at that date, received an Award of Merit. It is a very good apple, possessing excellent flavour and a very pleasing appearance, and it fruits well. I feel certain this variety will gradually make headway among our best dessert kinds, and, at some future time, be extensively grown and very highly appreciated. It is in season in September and October, and will keep later if well stored.

Lord Hindlip is a very good apple, and received a First Class Certificate in 1896. It is an Herefordshire apple, and well deserves a good position. I think it will soon be grown extensively for supplying dessert fruits after Christmas and onwards. Allington Pippin, introduced by Messrs. G. Bunyard and Co. in 1896, is so well known as not to need special comment from me, further than to say it is a good cropper. The fruits when ripe have a very pleasing appearance. The flesh is crisp, sweet, and nicely flavoured. Sometimes, on young, vigorous trees, the fruits are apt to grow a little above the average dessert size; but on older trees this is not the case.

Charles Ross is the result of a cross between Peasgood's Nonsuch and Cox's Orange Pippin. The fruits, when not too large, are very pleasing to the eye, taking rather more after Peasgood's than Cox's. It is a good bearer, and the fruits are good to eat; in fact, many prefer this to others with firmer flesh. It was raised about 1899, and, if my memory serves me right, a dish of fruits was exhibited at the Crystal Palace by the raiser in that year, and a very beautiful dish it was.

William Crump is a variety I have not yet grown myself, but the dishes of fruits that have come under my notice have been very handsome samples—nicely coloured, well flavoured, and not too large.

Ellison's Orange was raised near Lincoln by the late Rev. C. Ellison, and in 1911 received an Award of Merit. In 1912 a dish of eight fruits was shown at the great Autumn Fruit Show in a class for early dessert kinds not named in the schedule, and received the first prize, and as there were thirty exhibitors in this class it speaks well for the future of this apple. With me it crops heavily, both on espaliers and the bush form, and I hope to increase our stock next spring by grafting it on less useful kinds.

Christmas Pearmain is a most prolific apple. The fruits are somewhat conical, with a bright crimson cheek on the sunny side. The flesh is rather brisk or subacid, and firm. Although in flavour it is not equal to some other apples it is quite passable when fully ripe. It was introduced by Messrs. Bunyard in 1895.

May Queen crops A1 here, and the fruits put on a splendid colour. The flesh is firm, crisp, and sweet; in fact, I consider this is worthy of being more extensively planted both as a bush and standard. I have had good fruits keep till April, and sometimes later. I believe the variety was raised by Mr. W. Crump, but of that I am not quite sure; but whoever raised it deserves credit, for it is a very good apple.

Hitchin Pippin, introduced a few years since, is a good dessert apple in the way of King of the Pippins, which it rather too closely resembles. Maidstone Favourite, which received an A.M. from the Royal Horticultural Society on August 26, is an early dessert apple of much merit, the fruits being of rather large size, of fine form, and attractively coloured, and rich in flavour. This variety was raised by Messrs. G. Bunyard and Co., and is likely to prove one of the best of the many fine plants they have introduced. Crawley Beauty, which was raised by Messrs. J.

APPLE CRAWLEY BEAUTY.

A valuable late-keeping apple, suitable for culinary purposes and dessert, and handsome in appearance; raised by Messrs. J. Cheal and Sons, Crawley. A.M., R.H.S.

Cheal and Son, and received an A.M. from the Royal Horticultural Society a short time since, is a handsome apple of high quality, suitable both for cooking and dessert. The Guelph, which also received an A.M. at a recent meeting of the R.H.S., when shown by Mr. W. Pope, is useful both for culinary purposes and dessert, and the fruits are not less remarkable for their attractive appearance than for their high quality.

Cooking Apples.

Among cooking apples one of the best introductions in recent years is Newton Wonder. The fruits keep well, and the tree is most prolific as a standard. I have a tree, planted about ten years ago, and it rarely ever misses a crop; this year I have never seen such a splendid crop of good-sized fruits, the branches being completely roped from bottom to top. The Rev. W. Wilks and S. T. Wright, both of which have been introduced by Messrs. J. Veitch and Sons, are two new culinary varieties of great promise, and worthy of trial.

Pears.

Conference pear was introduced by the Messrs. Rivers in 1894, and, I consider, one of the very best of somewhat recent introductions. The pink flesh, melting and sweet, is all that can be desired. I have it growing as cordons and it seldom misses a crop; in fact, it is most free, and should be tried by all those who care for good pears. Charles Ernest will become very popular and somewhat extensively grown for supplying fruits in November and December. Michaelmas is a most delicious pear, greatly resembling Winter Nelis, but rather larger and earlier than that variety. It is a good bearer, and keeps longer than some of the varieties ripening at the same time.

Those who like a large-sized pear early cannot do better than plant Marguerite Marillat. It ripens in September, and the tree bears well. Although introduced in 1874 this has only recently become a favourite, and there is still room for more trees of it, especially in small gardens.

Santa Claus is a variety I have not yet grown, but one most highly spoken of by those who have it. Only recently I was asked by a first-class fruit grower if I had Santa Claus, and was told I ought to secure it at once.

Plums and Damsons.

New plums are of rare occurrence since the Messrs. Rivers sent out Monarch, Primate, President, and others. Among damsons I find Bradley's King one of the best, and that old variety, Farleigh Prolific, is a good cropper, but a new kind of very promising size and appearance, and one that should be given a good trial, is the Merryweather. The fruits are considerably larger than those of most other damsons, and they have a good flavour.

Soft Fruits.

Among the very best of recently-raised strawberries we have Laxton's Latest. The fruits are large, and the plants keep on fruiting for several days after others that begin to ripen about the same time have finished. Utility is a better-flavoured variety than most, the fruit is firmer, and the flavour good. We are increasing our stock of this. King George, quite a new variety, from the Laxton Brothers, is said to be earlier than the well-known Royal Sovereign, and better flavoured and brighter. If this is so, then we have here a splendid variety, and one that will quickly find a place in every garden.

Among autumn raspberries, Alexandra, raised by Mr. W. Allan, of Gunton Park, is, so far as my experience goes, the best. This season the young canes are literally crowded with finely-flavoured berries.

The loganberry is already popular, and those who prefer a black fruit of this kind will find the lowberry excellent.

H. MARKHAM.

Wrotham Park Gardens.

BLACK CURRANT MITE.

I fear that I have not anything very fresh to say upon the subject of the black currant mite, and at this busy season one has not much time for writing, and one's energies do not rise to any flights of fancy, so I shall confine myself to a relation of bare facts.

Perhaps it will be best to say how I become acquainted with the pest in the first instance. It was on this wise. When the Boskoop Giant currant first came out I was anxious to secure some trees, and wrote to a friend in Holland asking him to get some for me direct from the raiser so as to ensure having the right thing. My friend kindly made a journey to Boskoop, and arranged for some trees to be sent to me. These duly arrived, and were planted out—some for cuttings and some to fruit. In course of time these latter carried some fine fruit, with which I was much pleased, but in the autumn my foreman pointed out that the buds upon them were very abnormal in size. We had not previously seen these "big buds," but could not fail to recognise them as the work of the mite. Not only the new currants, but rows and rows of other kinds alongside were very badly affected, and, doubtless to a less degree, pretty well the whole of the stock.

This was bad enough, but the most annoying thing was that after writing to the Press, and saying this was the result of planting the far-famed mite-resisting Boskoop Giant, and slanging it for all I was worth, an expert from Boskoop came over, and made a journey to Lowdham, and at once declared that I was not growing Boskoop Giant at all, but Goliath or Victoria!

The question was now what to do. We sprayed the trees at intervals of about eight days from May to July with the ordinary quassia and soft-soap mixture, and found, in the next autumn, that the attack was greatly reduced, and the spraying had warded off all aphis, with the result that we had one of the finest blocks of black currants ever seen, and the admiration of all visitors. But, alas! the trees were not free from mite. Then I read the reports of Professor E. W. Collinge and others, from which I learned that the mites begin to emerge from the buds, not, as I supposed, late in April or early in May, but in March, and that they are ready to make an entry into the new buds at the very first possible moment. Acting upon this we started spraying early the next year, and smothered the poor defenceless mites, which were naked to the world, with soft soap; we kept up the spraying until June, the weather being favourable, and in the autumn, after careful search, we found somewhere in the teens of big buds in the whole of several large flats. Upon this I felt that I was justified in writing to the gardening Press, which I did in 1904.

Since that date I have, in company with inspectors from the Board of Agriculture, made careful search through flats of black currants so sprayed, and including quarters of Victoria (the most favourable variety for mite to attack), without being able to discover a trace of big bud. The inspectors did not quite believe in the efficacy of the remedy; possibly, like many of the general public, they thought it too cheap (it would be more valuable if sold at 3s. 6d. a pint), but I put this simple question to them: "Here you have a stock of currants which (speaking then) six years ago were infested with mite; now you cannot find a trace, yet these trees are propagated from tainted stock—and how have they become clean if the spraying has not done it?"

Since then several large growers have told the same tale, but there are, it must be confessed, difficulties in the way. First, the weather. You cannot spray when it rains, and the rain often does away with the benefit of a spraying. If you cannot, or will not, spray regularly you may destroy thousands or millions of mites, and still leave enough to stock a plantation. If you examine one big bud under the microscope you will think it contains enough mites to soon populate an acre of plants. That is the first difficulty, and the next is that when you have done everything you may get a fresh invasion from some neglected garden in the neighbourhood. If you examine the mites under a powerful lens you will see them sticking up on end and waving about, as if seeking to wrap themselves round something, and they are doubtless carried from one place to another by bees or other insects which visit the bushes.

As already stated, a few years ago we had not seen this pest. Now I find it from the English Channel to Northumberland; and in old gardens in which there has not been a fresh tree planted for ten years there are worthless old bushes covered with big bud. Some people say that certain varieties are immune. If so, I have yet to meet with them, but certainly some varieties resist the pest better than others. I cannot, however, see how it is possible to get rid of mite whilst most people look upon it as one of the things which cannot be helped—a sort of "act of God," as the law has it, and sit with folded hands. I think we must now class this infliction, with American blight (woolly aphis) and American gooseberry mildew, as things which can certainly be checked, and temporarily cured, but from which it will be difficult, nay, impossible, to guard against a fresh outbreak.

One word in conclusion. Don't attempt to rid your trees of mite by spraying unless you mean to stick to it and see the job through. So many people say they have tried it without success, and will afterwards admit that two or three sprayings were the extent of the trial. Even in high quarters results have been given upon the most slender evidence as to the spraying, and, even if one does one's best, a plantation may not be quite cured in one season. But persevere. The second season should free you, and you will be amply repaid by the clean, healthy growth of your vigorous trees. Needless to say that a large plantation will need the best of sprayers, and sufficient force to cope with the work quickly, so as to render the cultivator as independent of the weather as may be, and if you are not in a very isolated spot you will do well to keep up occasional sprayings in subsequent years as a preventive measure.

A. H. PEARSON.

Lowdham.

FASHION IN GARDEN FORMING.

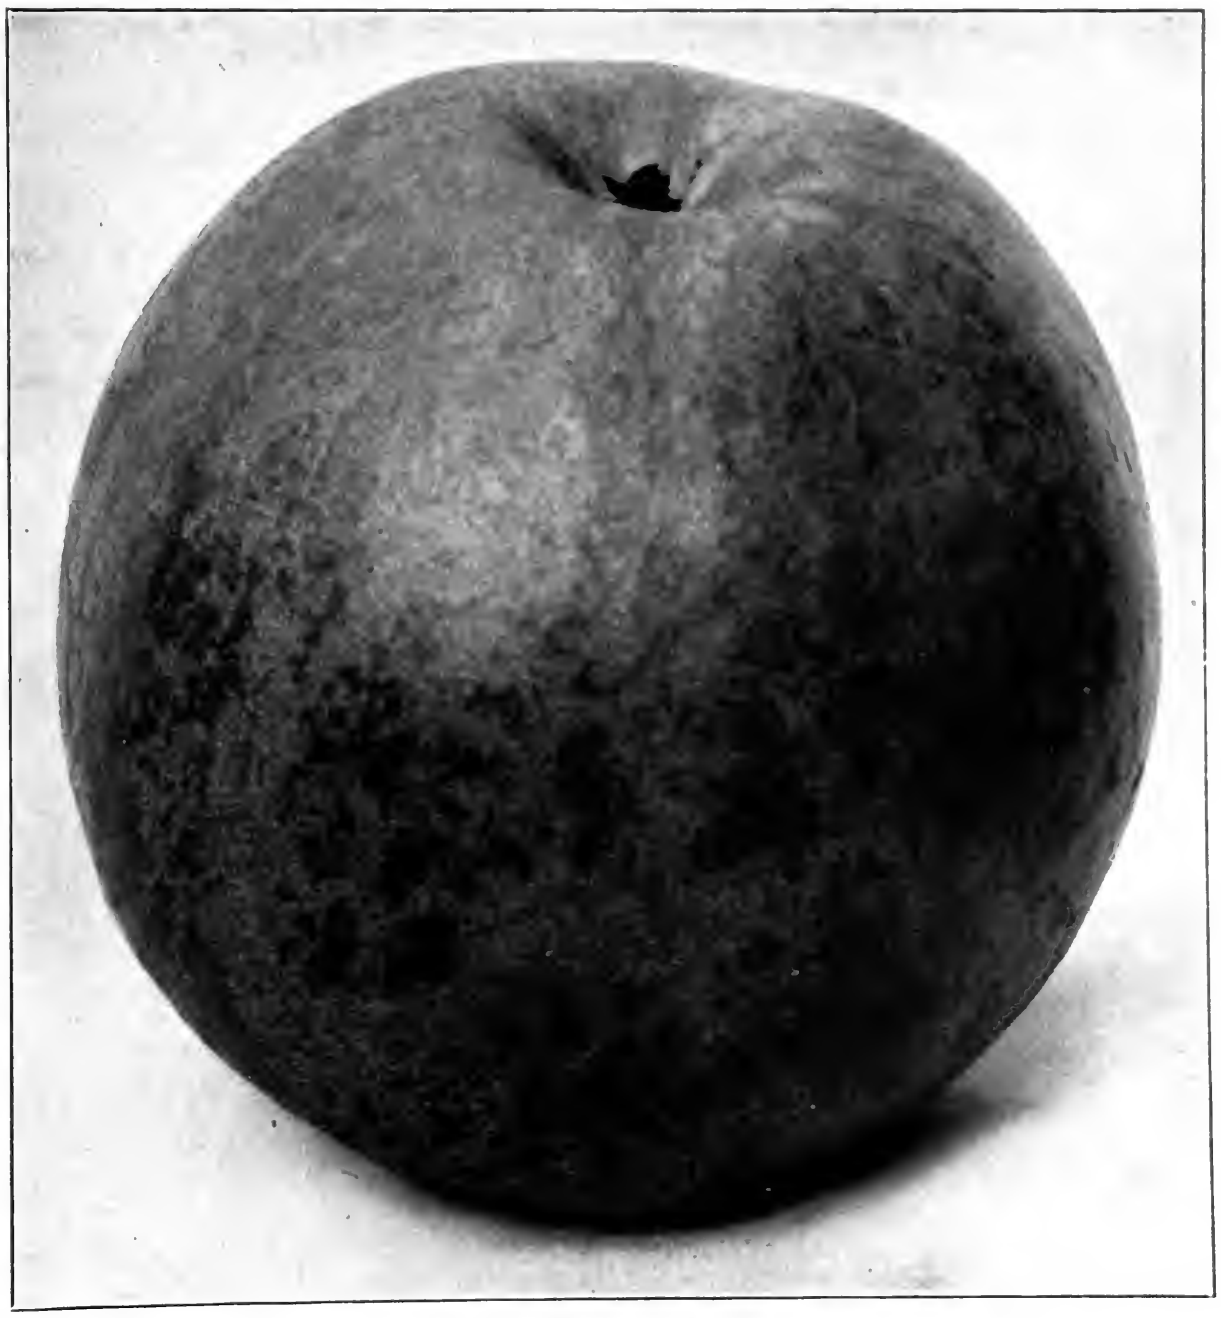
Theoretically a garden is formed when it is first laid out in paths, lawns, and walks, shrubberies, beds, and borders, but actually the forming goes on year after year, season after season. Not a plant can be added that does not materially change the character of the immediate neighbourhood, the lavish reproductions of Nature even speedily alter the face of the pleasure-grounds unless they are prevented or restricted.

Each summer season some difference in fashion affects our gardens just as surely as they influence our choice of clothes. Art has a great deal to do with gardening; it has been said lately that futurist and post-impressionist painters have helped to create the prevailing craze for vivid hues, and combinations of those in feminine attire, and that fashionable gardens are to exhibit correspondingly gorgeous contrasts. Probably flower-beds look more brilliant than of old, because colour-massing, the employment of but one or two hues, has taken the place of the antique practice of colour-dotting, the spreading out of patches of pretty tints over a large space. Fifty bushes of Madame Levavasseur, the dwarf crimson polyantha rose, for example, will give a show that could not be expected from fifty mixed polyantha roses; a couple of dozen orange-vermilion geraniums in a bed, with but an edge of snowy sweet alyssum, will long have a place in a memory that would not retain any impression of a bed made up, as beds used to be, of rings of scarlet, white, and salmon geraniums, with surrounding belt of gold calceolaria and blue lobelia. Renunciation is the road to more complete gain, just as specialising is the secret of most successes. By giving up five out of seven hues we extract infinitely more value from the two accepted.

Self beds are a notable fashion this year in several famous gardens. The object aimed at is the matching of a carpet or edging flower to the other kinds used, with such accuracy that, from a moderate distance, the eye will not perceive the slightest difference. Extra floriferous plants, too, will chiefly be made use of, those that clothe their foliage in blossoms. The fibrous-rooted begonias are admirable examples, so too are lobelias, the modern dwarf delphiniums that are treated as annuals, many varieties of the aster, sweet alyssum, violas, nemesia, annual candytuft, dwarf, erect eschscholtzias, Tom Thumb coreopsises, dwarf clarkias, godetias, and nasturtiums, and the showy silenes. Displays of carmine and royal blue are popular, for these hues in unison produce the effect of either strong violet or red-purple, according to the quantity of the carmine or the blue bloom. Salmon and orange are freely associated, one favourite idea being salmon clarkias from which rise at intervals by orange African marigolds of the most giant type. Rose-pink, of the shade of the cabbage rose, is accompanied by the gold of the bedding pansy or dwarf yellow nasturtium.

There are seen, however innumerable beds in softest pastel shades; where the grounds are of sufficient dimensions these are welcome as rest to the eye that has feasted on riotous splendours, but it is essential to their appreciation that they are so far from gay beds as not to be eclipsed by them. Other combinations of colour are china-blue with mauve, blush with silver-grey, bronze with the pale brown of some violas, Humea elegans, and one dwarf nasturtium. The azure-blue of nemophila is used with the dull pink of the viola William Niel.

Yet another feature of floral fashion is the present demand for plants of profuse but minute blossoms, that would have been reckoned insignificant by our ancestors. Probably the miniature lilac Ionopsidium acaule started the appeal two years ago; it was given as much praise as a stately dahlia or delphinium can receive; whole columns were printed upon its fairly-like charm. Now we have many rivals, gypsophilas of dwarf as well as tall habit, from the six-inch muralis to the three-feet G. acutifolia, Isatis glauca, or Woad, a three-feet plant smothered in fragile-looking yellow florescence; Tunica saxifraga, eight inches, pink and white; Artemisia gracilis, a tall, feathery foliage subject that buds out in fluffy gold bloom at every shoot; and the twelve-inch white gypsophila, resembling Asperula hexaphylla, in addition to the multiflorus section of Michaelmas daisies, the plume-forming Bocconia cordata, astilbes, amaranthus, and celosias.



APPLE THE GUELPH.

A handsome and productive apple of high quality. A.M., R.H.S., September. Mr. W. Pope, Newbury.

The newest way of growing sweet peas is by placing single plants against bamboos at half-yard intervals, and carpeting between with alyssums or violas. It is considered that a mixed bed, with a different colour to each stick, has a charming effect, and serves to show off the distinctions between varieties.

Lastly, taste is beginning to tire of arches and pergolas. The latest fashion for growing climbing roses and clematises is up larch poles, set at irregular intervals in a large group on a lawn, or out of a gravel square. The branches are crossed and re-crossed in imitation of the way in which Nature forms copses and thickets, a semi-roofing being thus gained to shelter chairs. The same scheme could be carried out in a summer with canary creeper and other tropæolums, and Convolvulus major. M. H.

CISTUSES.

The following three species of cistus are desirable where the shrubbery borders are spacious.

C. monspeliensis.

This is an upright-growing plant with twiggy growths, in general habit not so robust as most of the other species mentioned. The leaves are narrowly lanceolate, the flowers, which are very freely produced, being white, about an inch across, borne in clusters of five to ten or more. The average height of the plants is about two feet.

C. purpureus.

A bush of the true purple-flowered rock rose in full flower at the foot of a sunny south wall is worth going a long way to see. Unfortunately, it is rare, no doubt because it is rather more tender than some of the species, growing two feet to four feet high, the leaves oblong-lanceolate, the flowers two inches to three inches across, rich reddish-purple in colour, with the familiar yellow centre, and velvety-maroon blotches. The true C. purpureus is very rare, one or other of the varieties of C. villosus often being grown as C. purpureus.

C. villosus.

This is the commonest of the pink or rose-coloured cistuses grown in gardens, and is very variable. C. creticus and C. undulatus are both varieties of it. It forms a compact bush, with greyish, hairy leaves, and rosy-purple flowers about two inches in diameter. The species and its varieties produce seeds very freely. A. O.

ADVANTAGES OF ORCHARD HOUSES.

Much might be written and said with reference to the aid well-equipped orchard houses are able to render in the maintenance of supplies of choice fruits during the greater part of the year, but there is no occasion in these pages to do otherwise than briefly touch upon this point. We have, on more than one occasion, within a comparatively short period, set forth at some length the advantages of having one or two structures in the garden for the cultivation of fruit trees in pots; and last winter we were fortunate in being able to arrange with Mr. James Hudson, V.M.H., to write a series of articles on the fruits specially adapted to orchard-house culture. As Mr. Hudson is a past master in the art of growing fruit trees in pots, his contributions received widespread attention, and greatly stimulated the interest in this phase of fruit production

We now refer to the matter for the purpose of presenting our readers with an object-lesson that is unquestionably of great practical importance. This year plums, more especially the choice varieties, have been so scarce that even those who have trees trained to walls have had a difficulty in maintaining moderate supplies either for dessert or kitchen use. Pears very closely approached a complete failure, and it must have been very disheartening, both to owners of gardens and those responsible for their management, to have scores of admirably-managed trees without a fruit upon them, or so few fruits as to be hardly worthy of notice.

Whereas out of doors hundreds of plum and pear trees have been barren, there has been no shortage of orchard-house fruits. In gardens where fruits are grown in pots the crops have, as usual, been heavy, and of high quality, and in nurseries also the pot trees have been an interesting and profitable feature. We have only to refer to the magnificent collections of fruit trees that have of late been exhibited by the leading nurserymen at the Royal Horticultural Hall to remind many of our readers of the great excellence of the crop. For the purpose of enabling those of our readers who had no opportunity of seeing the fruit trees shown at Westminster, we illustrate two trees which are fair examples of the whole. One is a tree of that excellent early dessert plum, Early Transparent Gage, which must have furnished three or four dishes of finely-developed fruit, and the other that useful autumn pear, Souvenir du Congrès, which had about eighteen large fruits. Both trees were excellent examples of successful culture, and were exhibited with a large number of trees, all more or less good, by Messrs. J. Veitch and Sons, at one of the late summer shows held by the Royal Horticultural Society.

PLUM EARLY TRANSPARENT GAGE.

A heavily-fruited tree of this useful dessert plum, showing its value for orchard house culture.

THE BEST TWELVE EXHIBITION FRUITS.

During the months of August and September, from a large establishment where fruit is a speciality and there are crops under glass, it should not be difficult to stage at the leading exhibitions a collection of twelve kinds of fruits, and these of superior varieties.

It is very strange that in some collections we find so many inferior varieties. By inferior I mean grapes like Gros Maroc, Alicante, or Gros Guillaume; Emperor Alexander or Gascoigne's Scarlet apple. No one will admit that these possess really high flavour, and yet we often see them included in collections of dessert fruits. The apples have certainly only a bright exterior to recommend them. In the case of the grapes it is astonishing how exhibitors cling to these inferior varieties when the more desirable sorts can be quite as easily grown. How can either of the grapes named be compared to Black Hamburgh in August, Madresfield Court or Muscat Hamburgh in September?

Gardeners, as a rule, confess to a weakness for variety in grapes as in all other fruits, and in vegetables and flowers, but unfortunately it is at the expense of quality in far too many instances. I cannot understand why, instead of so much variety, double or treble the number of vines of a superior variety are not planted in preference to one or two canes, each of a considerable number of varieties, none of which are indifferent in quality.

As a guide to the inexperienced I purpose giving a selection of the best twelve fruits suitable for exhibition during the two months mentioned and the varieties best adapted to such a purpose, bearing in mind only those that possess merit beyond appearance.

For exhibition purposes black and white grapes are regarded as distinct kinds of fruit. In addition to these I name pine-apples, peaches, nectarines, melons, figs, plums, pears, cherries, apples, and apricots or strawberries. This is giving a choice of thirteen kinds, without having recourse to currants, gooseberries, raspberries, or nuts, none of which score many points in competition.

For use in August the following varieties would be unsurpassable if presented in the best condition each is capable of.

Black Hamburgh I regard as the finest black grape during the month of August. This variety has a flavour all its own when presented at its best. Bunches 3lb. to 4lb. in weight, evenly-shouldered, furnished

with large even-sized berries that have a distinctly hammered appearane, are quite black, and covered with dense bloom. If all these attributes are present no one could suggest a more perfect specimen of a black grape.

Muscat of Alexandria is far ahead of all other white grapes at that season of the year. The bunches should be 3lb. to 4lb. in weight, evenly shouldered, tapering, and regularly furnished with large, even-sized, oval-shaped berries of that rich amber tint which is so pleasing in this grape. Of pineapples no variety equals a regularly ripened fruit of Queen in point of quality. Smooth Cayenne is larger and more handsome.

Of peaches, Royal George and Bellegarde are quite the best, both for appearance and high quality, and although Alexandra Noblesse may possess enticing flavour, it is short of the rich colour the two former varieties have in combination with their own rich flavour. In nectarines, Pineapple and Elruge are desirable having a distinct type of flavour, but both are good and reliable in growth and bearing qualities.

Melons are numerous, but in spite of its age and the immense number of new introductions, Hero of Lockinge is still difficult to excel in appearance and flavour. Sutton's A.1, if a scarlet-fleshed variety is required, is desirable. No fig can yet equal Brown Turkey in point of quality, although Negro Largo may be larger. In plums we have abundant choice, but Golden Gage and Jefferson are well flavoured. Pears are well represented by Doyenne du Comice and Louise Bonne de Jersey. Among apples no variety is needed but Cox's Orange Pippin, because no other can equal it in flavour. Varieties like Charles Ross and Gascoigne's Scarlet are quite out of the running.

Cherries are best represented by Black Circassian (commonly known as Tartarian) or Knight's Early Black. Of apricots, Moorpark still leads the way. Strawberries in August are not easy of production, but Waterloo is the most reliable for that period.

For exhibition in September some slight alteration will be required in some few varieties. In Black grapes, Madresfield Court or Muscat Hamburgh should be substituted, as it is not an easy matter to preserve the colour of Black Hamburgh in September; and, besides, these are at their best flavour in September. Of all grapes perhaps Muscat Hamburgh is the more difficult to grow in a general way. The bunches do not come so shapely, nor do the berries "set" so freely, but of all high-flavoured grapes this is undoubtedly the best.

Violette Hâtive and Stirling Castle peaches should be grown to take the place of Royal George and Bellegarde, as these cannot always be had in September. Pitmaston Orange nectarine may perhaps take the place of Pineapple for September use, as it keeps fresh longer without the skin shrivelling.

In pears Marguerite Marillat will take the place of Louise Bonne de Jersey, but for Doyenne du Comice there is no substitute. In apples Cox's Orange Pippin still holds the first place, and no other is required. Givon's Late Prolific is an excellent late strawberry, and for September use should be encouraged. The latter should take the place of apricots, and, failing these, autumn-fruiting raspberries must be substituted. Of these latter Alexandra and Hailsham are fine varieties, and so is November Abundance. Among cherries Morello is quite the best for extreme late use.

PROMOTING THE FERTILITY OF FRUIT TREES.

In the general routine of a garden the periodical root pruning of fruit trees is an important item, especially where satisfactory crops of fruit have to be maintained from trees that have their branches shortened. Experience teaches me that it is better to copy and help Nature than to create distortions, but this is not always possible when dealing with fruit trees on walls, espaliers, or those grown as pyramids and bushes by the sides of walks. In their case it is necessary to use the knife to keep them within bounds, and in doing this the balance between the root and branch is upset.

The result of this condition of things is invariably strong, succulent, unfruitful wood, provided the soil in which the trees are growing is at all fertile. Another cause of this succulent growth is annual digging of the ground occupied by the roots of the trees, the fibrous, mineral-absorbing, fruit-producing roots being thereby destroyed, thus forcing the tree to seek its sustenance from a less favourable stratum. These conditions, too, no doubt, tend to foster canker in the stems and branches, for when the soft, badly-ripened wood experiences a severe winter the tissues

PEAR SOUVENIR DU CONGRÈS.

An excellent autumn dessert pear of much value for orchard house culture.

are injured, and decay, in the form of canker, not infrequently sets in.

To avoid all the evils of this kind, keeping the trees strong and vigorous, and always in a fruiting condition, should be the aim of every grower. The evil of rank growth is sometimes aggravated by inclement weather destroying all the bloom. Trees, therefore, without a crop of fruit to develop and perfect, especially if growing in a soil rich in organic matter, quickly run to soft wood when thus unbridled. It is with trees of this description that root pruning becomes imperative if they are once more to be brought back to fruitfulness.

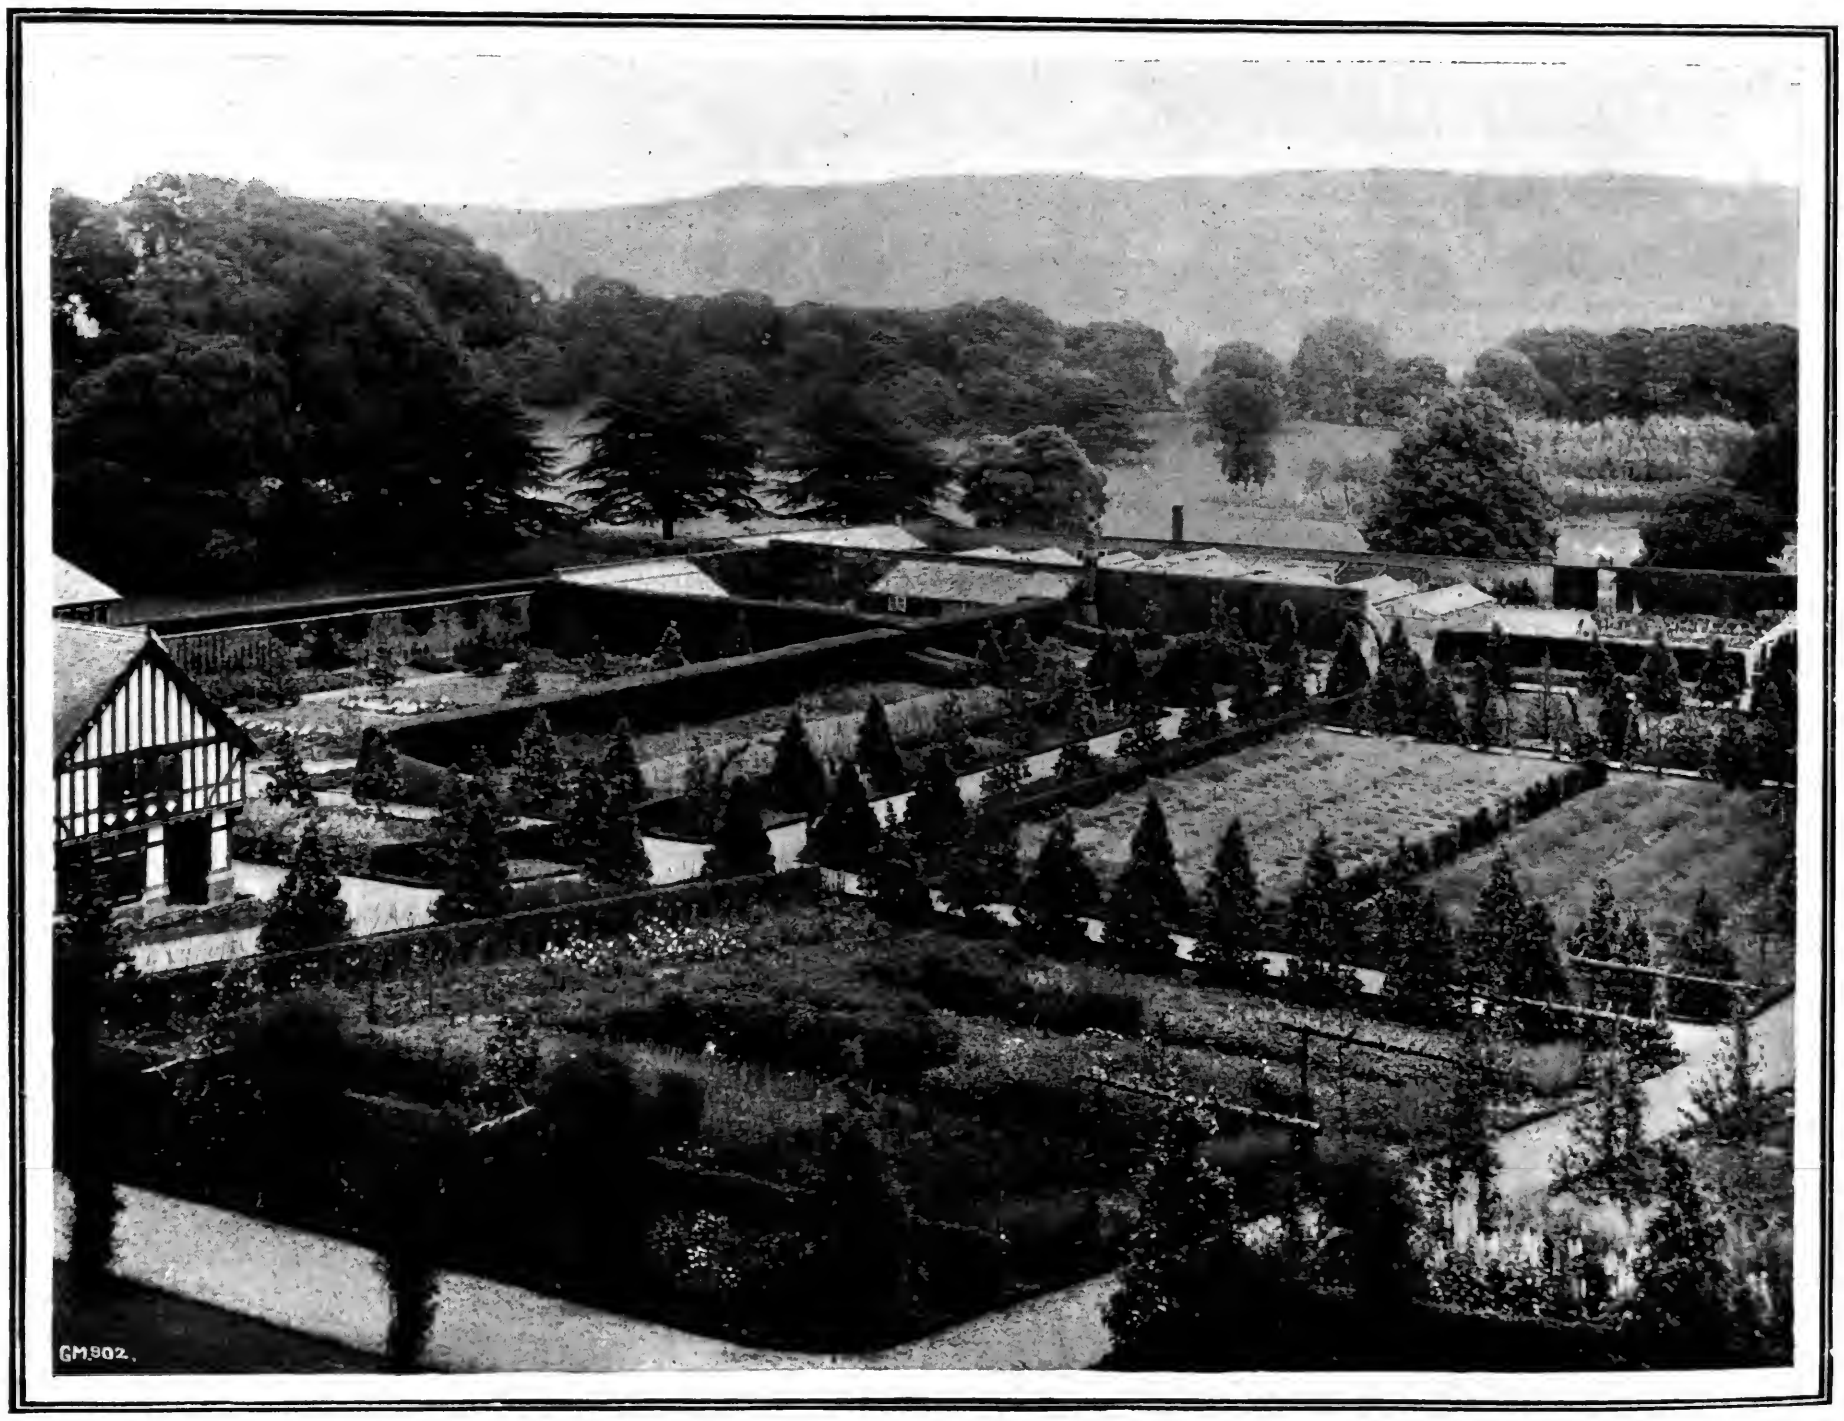
The operation of root pruning is both a check and a stimulus to the trees, as it is the means of cutting off, to a certain extent, the supply of nitrogenous food, and creating fibrous roots, which increases the trees' ability to obtain a larger supply of mineral matter. Knowing this, our method of root pruning is to work round a tree at a certain radius from its stem, according to its size, but, as a rule, from two and a-half to five feet, with a trench two feet wide, and work down the same depth. In the process all the roots of a fleshy nature met with are cut, and all the fibrous ones that can be saved are retained. In most instances it is advisable to get right under the tree from one side to cut away any tap roots.

At this stage much can be done to ensure a plentiful display of fruit buds twelve months hence, i.e., by providing an ample supply of fruit-producing plant food constituents within the reach of the young rootlets that will be formed the following year. The best fertiliser for this purpose is finely-ground bonemeal, or equal quantities of bonemeal and superphosphate. In returning the soil to the trench either of these (or, if the soil is heavy and rich in humus, basic slag) should be mixed with it. The quantity, provided there is plenty, does not matter, as these valuable plant foods do not go to waste, but remain till taken up by the roots. Where there is a deficiency of lime in the soil there should be a surface dressing of from four to eight ounces to the square yard of slaked lime in March. In cases where the potash is limited in the soil two ounces of kainit to the square yard at the time the lime is applied will have beneficial effects.

HIBERNIA.

PYRAMIDAL FRUIT TREES AT POWIS CASTLE.

The illustration of the kitchen garden at Powis Castle that we have the pleasure of giving herewith is of much interest as evidence of the success achieved at this famous Welsh seat in the cultivation of pyramidal fruit trees. It is of interest also as a proof that the importance of fully exposing all parts of the trees to both solar light and a free circulation of air is recognised as essential to the production of abundant crops of finely-flavoured fruits. At the present time the pyramidal style of training is not regarded with so much favour as it was by the past generation of fruit growers. Yet one cannot repress a feeling of admiration for the skill of those by whom these trees were planted, and have been brought to their present high degree of development. Shapely trees of pyramidal form, such as those at Powis Castle, have lost some degree of their popularity owing to the style of training necessitating severe pruning, which is not conducive to abundant fruit production. Much, of course, depends upon whether the trees have the advantage of skilful management or otherwise, for skill of the highest class is of greater importance in the case of trees that have to be severely pruned to maintain them of the desired form than when the trees can be allowed to grow more or less naturally. The gardens at Powis Castle have been under the management of gardeners of the highest eminence, and, as the result, the formally-trained pyramids, while a constant source of attraction, have yielded an abundance of fruit of the highest quality. Special attention may with advantage be directed to the fact that the trees are arranged far enough apart to enable them to be fully exposed to the rays of the sun on all sides, and to allow the air to circulate freely through and around them. It will be noticed also that the spaces between them are kept free from vegetation of all kinds, thus rendering it possible to maintain the surface soil in a loose state, so important as an aid in the prevention of an excessive rate of evaporation. In addition to the advantage of being able to use the hoe freely, the cultivator is able to readily apply rich top-dressings as may be considered desirable.



PYRAMIDAL FRUIT TREES IN THE KITCHEN GARDEN AT POWIS CASTLE.

Acalpha hispida.—Grown for winter effect, the acalphas are now developing their tassels, and water must not be allowed to come into contact with the latter, or they will quickly damp; at the same time, the atmosphere must not be allowed to remain dry, or an attack of red spider may be expected. A careful lookout should be kept for this pest, and also for white scale, and should either be detected careful sponging with an insecticide should be resorted to.—H. PRIME.

CORDON APPLE TREES.

There are benefits to be derived from training the apple upon the cordon principle that cannot be claimed for any other method, and the greatest is that it permits a larger number of trees to grow upon a restricted space than by any other system. This is especially helpful to owners of small gardens, as, apart from other gains, it allows them to cultivate a greater number of varieties, and, in this way, provided they select suitable ones, secure a longer succession of fruit they they otherwise could do. This mode of training is also simple, can therefore be easily understood, and involves no difficulties in pruning; moreover, the trees commence to crop at a comparatively early stage, and, under painstaking management, they are distinctly prolific, and produce fruit of excellent quality.

Training.

In training cordons there are different modes adopted, each suitable for some special purpose. The most simple form—the single cordon, for instance—is the most suitable one to be grown horizontally, and is in some cases made use of in this way by being planted and trained to wires, placed near the ground, by the sides of kitchen garden walks, to which it affords a pleasing and profitable margin. It can be most profitably utilised, however, if the trees are planted against walls, buildings, trellises, rails, etc., and in these positions it can be trained vertically or obliquely. For positions of this kind that are low, or only moderate in height, the oblique system is preferable, as it permits the trees to attain a greater length than does the vertical method. It is also claimed for this form that the trees' vigour is more generally equalised than is the case with upright trees, which have a tendency to become weak in growth near their base as compared with the tops.

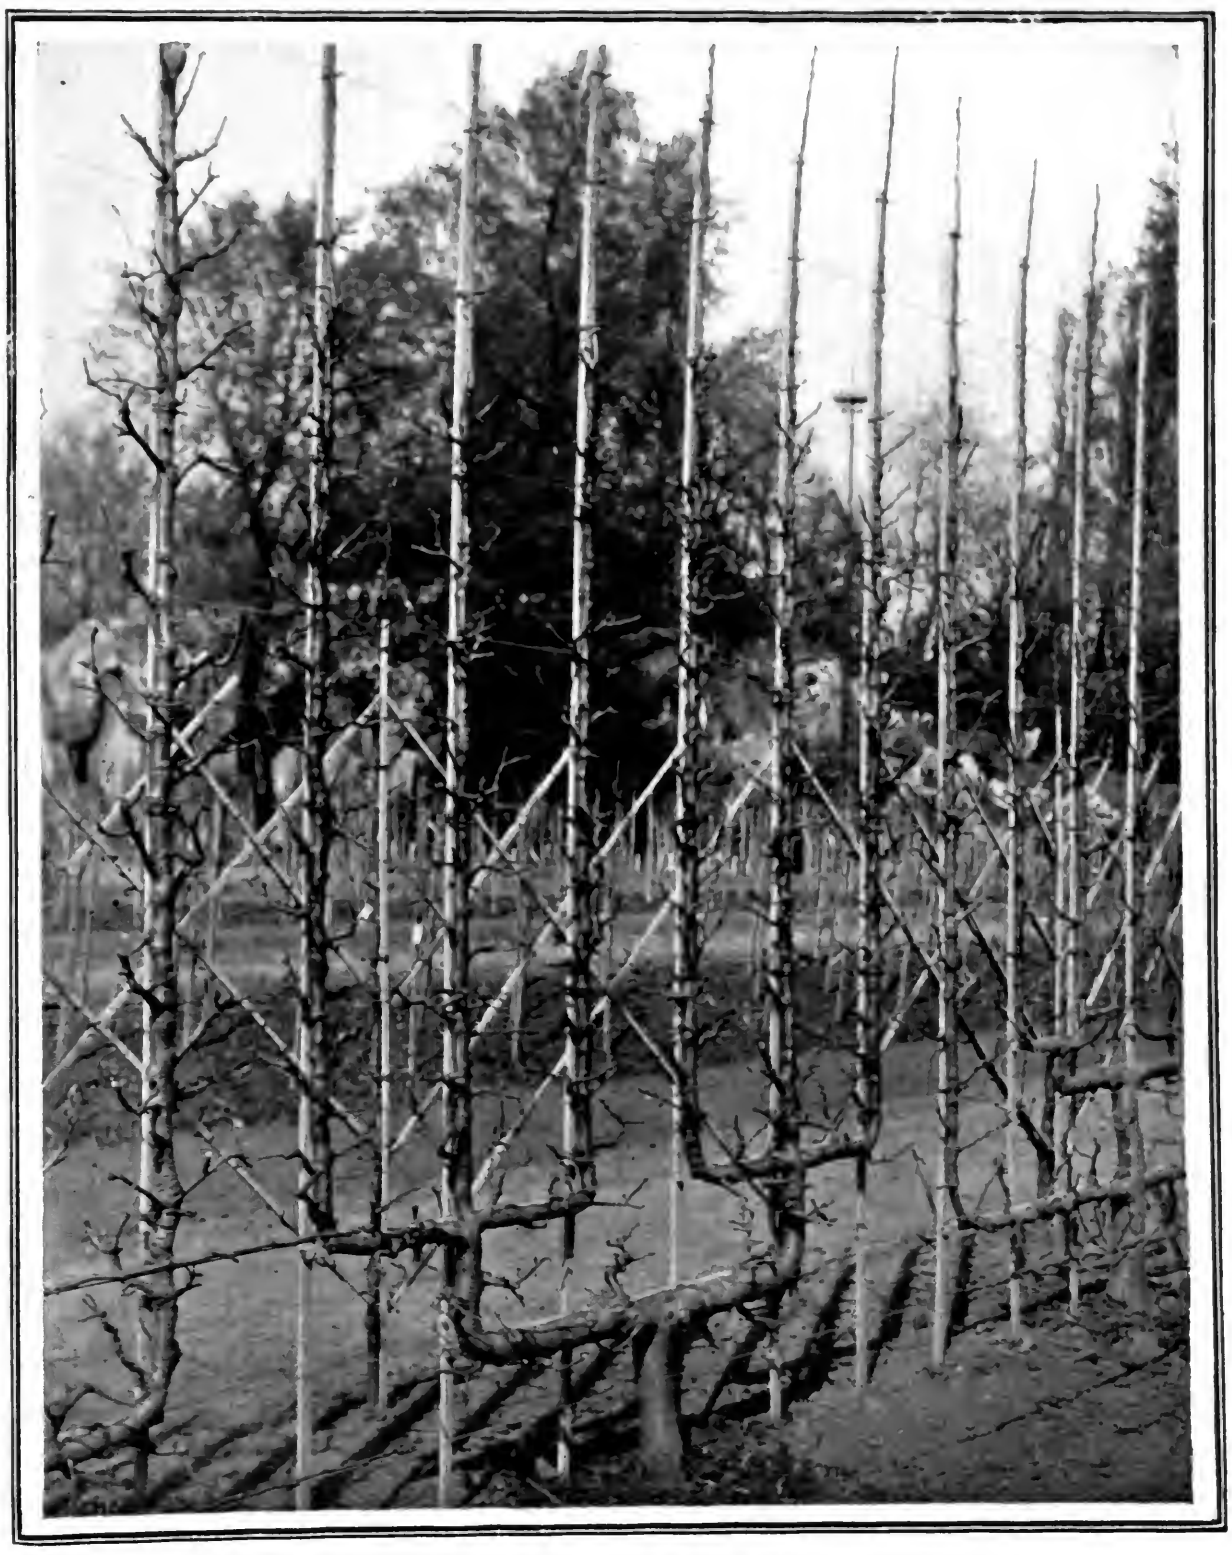
The double cordon, and those with still more branches, are best trained vertically. Apart, however, from the obvious difference in management during their early stages of development, they require similar treatment to the vertical single cordon. Yet, owing to the difference referred to, they require more time to cover a given space and to become fruitful than do the single cordons.

Planting.

When preparing for planting, the land, if it is necessary, must be drained, and in any case it should be trenched two feet in depth. If this can be done at a sufficient length of time previous to the planting season for it to become settled, an advantage will have been gained. The method of trenching adopted should depend upon the nature of the soil. Should this be of an equally good character throughout, the bottom should be brought to the surface, but otherwise it should be merely well broken up, though in any case the surface should be made fine and even to receive the trees. Early in November is the best season in which to plant; and a time when the soil is in a fit condition, i.e., sufficiently dry to crumble, should be chosen for the operation.

The trees selected should be worked upon the paradise stock, as their growth is more suitable than in the case of those upon the free stock. The distance from each other at which the trees are planted must, of course, be governed according to their description; for instance, single vertical cordons should be placed at least one foot apart, while those of other forms should be so arranged that their branches are also this space from each other; and each, if placed against a wall, should have its base two inches removed from it. Each summer stopping, pruning, and training of shoots, the winter pruning, and, in some cases, root pruning; and although these operations are comparatively simple, it is nevertheless essential that the practitioner understands the characteristics of the various forms of growths, for the fruit-bearing powers of trees, especially of those that have their growths so severely restricted as the cordon has, depends to a considerable degree upon the way in which pruning is carried out.

The requirements of the trees with regard to stimulants, such as mulching, manuring, and watering, must also be closely attended to, as the health of the trees and the quality of the fruits in a great measure depends upon this. Another matter of importance is that of keeping the trees clean and free from insect, fungoid, and other enemies.



CORDON APPLE TREES WITH SEVERAL BRANCHES.
Trained in the form commonly known as the gridiron.

tree, before being planted, should have all broken and jagged ends of roots cleanly cut off, the cuts being made from the under sides. Their roots must be carefully spread, have fine particles of soil worked amongst them, and be firmly embedded at a depth of about three inches. If the natural soil is unfavourable to plant in, much benefit will result from the use of a specially-prepared compost. These operations should be completed by mulching with partially-decayed stable manure.

Subsequent General Management.

To describe this in detail would fill too much space, but the chief operations may be briefly referred to. They consist of the

Suitable Trees for Planting.

Though any variety of apple can be cultivated, with more or less success, upon the cordon principle, strong growers that produce large, untidy spurs are not so suitable as those of neat habit, that naturally form spurs close together, and selections of varieties of this description can be made from the dessert and culinary sections. Trees prepared for planting can be obtained from any nursery in which fruit trees are made a speciality.

Thos. Coomber, V.M.H.
The Hendre Gardens.

CHERRIES FOR GARDENS.

Medium light soils, containing sand and a little lime or chalk, are best suited to cherry culture. The trees can be grown very successfully in many open gardens, but, generally speaking, they are more easily protected when trained on walls. As a rule, the amateur grower will discover the greatest amount of utility in the Morello cherry. This seems to thrive in almost any soil and situation, but a fairly warm spot and a light sandy soil is best. It succeeds equally well as a standard, bush, pyramid, or espalier, and quite small trees in a young state will fruit abundantly, the fruit being particularly adaptable to preserving, bottling, or for ordinary cooking purposes.

For ordinary garden culture, however, there are, of course, other kinds, besides the Morello, that suit the amateur and professional grower quite well. In a moderate-sized garden, for instance, Early Rivers, a magnificent black fruiting variety, with large glossy fruit, borne in clusters of ten or twelve, is an admirable cherry for dessert purposes, as also is Black Tartarian, which does best against an east wall. As a bush or pyramid tree, against an east wall, Archduke does very well indeed, especially in a chalky soil; in fact, all the Duke cherries are most suited for chalky soils. There is also May Duke, a large red cherry, with an agreeably acid flavour; Elton, with a large mottled fruit; Bigarreau Napoleon, which succeeds best against an east wall or as a standard; and Kentish, a medium-sized cherry for culinary use, juicy, and acid in flavour.

New varieties of cherries are raised from stones, the seedlings being transplanted out in nursery rows in the autumn of the second year. Standard trees and strong-growing kinds like Bigarreau are commonly propagated by means of grafting on stocks raised from the gean, or wild black cherry; or, in the case of dwarf trees and such kinds as May Duke, Morello, etc., on stocks raised from Cerasus Mahaleb. Scions for grafting cherries must be taken early, in February, if possible, and heeled in in a cool spot until required in March.

Symmetrical training is quite easily accomplished in the case of cherry trees. At the outset young trees are best allowed to make one year's growth, after which they need to be cut back twelve or fifteen inches towards a bud or "eye" pointing in an outward direction. Two shoots should be encouraged from each branch. Wall trees should always be trained fan fashion, while bush trees must be kept open, and the branches well exposed to light and air. The cherry certainly does not lend itself to knife pruning like other stone fruits, and the only time when the trees need attention in this direction is when they are young. Sometimes a strong woody growth is developed in the first year, but this can be checked by lifting and transplanting in the autumn, after first shortening any strong-growing roots which would be responsible for this over-luxuriant growth. In the case of a standard tree, at any rate, the knife must not be used at all after the first year's training and shaping, although, of course, the dead wood must be thinned out and cross-growing branches kept in order. For wall-trained trees a system of summer pruning or disbudding is best adopted, which consists in shortening the current season's shoots to within two buds of the base, and pinching out the growing points on the laterals or wood growths of young trees so as to form fruit buds.

In the case of the Morello cherry, it is to be noted that here the fruit is borne on the wood of the preceding year's growth, hence the weakest shoots, and some of the old wood should be cut away every year so as to prevent overcrowding. This variety grows very successfully against a north wall. Of course, the great point to bear in mind in pruning cherries is that wood buds must always be left wherever extension branches are required. As a rule, however, it is best to rely upon disbudding in spring rather than knife pruning in winter. Perhaps the best way of checking the too exuberant growth of young trees, which may be developing an excessive amount of stout shoots, is to carefully lift and transplant them.

Frequently the grower is troubled with "gumming" in cherries, which, as a rule, is directly attributable to a too free use of the pruning knife in winter. It may be obviated by keeping the roots of the tree close to the surface; these are naturally surface travellers, and so this treatment will promote the growth of short natural spurs, which will tend to encourage the formation of a healthy tree. Of course, the best way to avoid gumming in any variety is to attempt as little winter pruning as possible, this, if necessary, being always reserved until the time when the trees are in full leaf.

Old Basing.

SOIL PREPARATION FOR FRUIT TREE PLANTING.

After many years' experience in hardy fruit culture, I am the more convinced that many failures occur owing to faulty methods of preparing the soil before planting. Too many people shirk the trouble and expense of thorough preparation; they are content to prepare a station for each tree, and promise to extend that preparation when the roots of the trees have fully occupied the first prepared site. I have seen so much of the evil results of such half-measure methods that I cannIot recommend them, because I am positive the future welfare of the trees is jeopardised, except, of course, in the hands of a few exceptional growers.

I remember an instance of bad preparation in an orchard of some six acres, some thirty-five years ago. The soil was a good loam, overlying clay that badly needed draining. For each tree a station some 6ft. in diameter was prepared. The trees were planted in good soil, and grew away vigorously for a time until the roots reached the limit of the prepared site; then they received a check, as every station became a receptacle for surplus water, and the trees quickly presented a sorry sight.

A new gardener was appointed; he saw the plight of the trees, and correctly divined the cause. He first drained the whole plot, and trenched it 3ft. deep, replanting every tree as the work proceeded. The result was magical; the trees are to-day perfect specimens of what an orchard tree should be, and they are not sprayed, beyond an occasional washing with an alkali mixture for the removal of moss and lichen—which, by the way, does not flourish there now owing to the more favourable rooting conditions. The trees never seem seriously troubled with insect pests; and it is safe to say that the orchard in question is one of the best in the country. It is not an unusual thing to gather from twenty-five to thirty bushels of apples from one of the trees. The varieties are also of the best.

From this it will be readily assumed that I advocate deep trenching when dealing with soil of a heavy, retentive character, not actually clay but a near approach to it, which, below the eighteen inches of loam on the surface, has a hard pan of subsoil thickly studded with flint stones. These flints, if allowed to remain in the soil after being loosened, obviate the necessity of artificial draining, and therefore are a distinct advantage, not only in saving expense, but in assisting in the aeration of the soil.

There are two methods of trenching the soil; one is that of burying the surface soil at the bottom, and bringing the bottom to the top. If soil so treated could be trenched again within two years, then I agree with the plan, or if the surface can be covered over six inches thick with any lightening material, like road-side refuse, then I say this method of trenching is desirable. The second plan is to keep the surface soil in the same relative position by having two trenches open at the same time, and thoroughly breaking up the bottom of every trench to admit of the quick percolation of surplus water. If the soil is poorly drained, the roots quickly become unhealthy, encouraging canker, and reducing the vigour of the trees. As a result the leaves in their weakened state quickly fall a prey to insect pests, especially greenfly, which does untold damage by preventing the swelling of the fruit, and retarding the development of fruit buds for the next year's crop.

Trenching should be done fully a month before planting, to allow the soil to settle down. If the whole plot, large or small, is to be wholly planted with apples, pears, plums, etc., with bush fruits and strawberries between, then I recommend a dressing of farmyard manure at the rate of twenty-five tons to the acre, this to be added to the top spit of soil Placed at a greater depth manure only encourages the trees to root deeply, and that is not desirable, for the closer to the surface the roots can be kept the better, for they obtain much benefit from sunheat, thus inducing the trees to make desirable growth, which matures gradually as it proceeds. When planting in such soil, the trees benefit considerably by the addition of some light material about the roots, especially wood ashes or decayed leaves.

In the case of sandy loam, all that is needed is to deeply dig the soil, adding half-decayed manure in moderate quantity at planting time. Generally trees grow freely in such soil, without the aid of manure, until they are bearing full crops of fruit, when they need assistance.

When preparing to remove wall trees that are worn out, it is wise to remove the whole of the soil (if the new trees are to occupy the same site) for a distance of 6ft., filling in the space with soil from a part of the garden that has not previously grown fruit trees. Correct the drainage where necessary, and add a prepared compost for the roots, with a small quantity of half-rotted manure.

Freshly-cut turf is quite a desirable ingredient to employ when planting fruit trees, and, if the opportunity occurs, a quantity should be prepared and cut ready for mixing with old lime rubble, especially for peach and nectarine trees. Any extra attention of this character that can be given to fruit trees at planting time will result in successful growth the first year, which should be the foundation for future success.

E. M.

Clematis Jackmani.—It is an open question how many varieties of clematis have been put into commerce since this was distributed now many years ago, but it is not yet superseded—in fact, it must still be regarded as one of the best of all clematises. What is more, it seems to be less affected by disease than many others, and fine examples may often be seen among very uncongenial surroundings even in towns.—W.

Kelway
of Langport, Somerset

LOVELY DELPHINIUMS

Kelway's Delphiniums grow to a height of from four to eight or more feet and bear masses of fine shapely blooms in all shades of blue and purple. They thrive with a minimum of attention in almost any soil and situation, and they provide a bold and beautiful show either massed by themselves or as a part of the Kelway Colour Border.

KELWAY COLOUR BORDER (Regd.)

To secure absolute perfection in your Herbaceous Border, stock it with Kelway Hardy Perennials. Their bold forms and lovely colours represent the outcome of years of patient experiment and hybridization, while they are raised from such strong country-grown stocks that they may be depended upon to flourish under almost all conditions of climate.

AUTUMN-FRUITING RASPBERRIES.

In a paper read before the Fellows of the Royal Horticultural Society in the autumn of 1903 on the autumn-fruiting raspberries (and strawberries), I said: "These fruits, so well known and so much appreciated in the summer season, have not, until within the past year or two, been duly recognised for regular supplies in the autumn. My object in detailing our mode of procedure at Gunnersbury is to encourage and extend their cultivation for autumnal supplies."

Their Utility.

These remarks, made ten years ago, I again repeat as an introduction to what is now recorded of our present system of cultivation. True, one does now find more of these fruits in private gardens than in 1903, but the increase has not been commensurate with the merits of the autumn-fruiting raspberries. We find these (and the strawberries, both the alpines and the perpetuals) to be much in request both for dessert and for various confections. They are used now (October 15) almost every day in both ways. For breakfast they are always found welcome; also for teas, and even for the dessert on the dinner table. The quality of the fruit is better, on the whole, than with the summer-fruiting kinds. Then the flavour is oftentimes too sweet; now it is sweet also, but with a sparkling acidity and freshness combined.

This season we have been picking since the first few days in September, and now we are picking more than at any previous date. (Six punnets are now being gathered for confections for one special occasion; this we shall frequently repeat.)

Lately we have, in common with other districts, had heavy downpours of rain, and in such quantities and duration as would, to some extent, damage the summer crops by reason of the humidity in the atmosphere. Not so, however, with the autumn crop to anything like the same extent. One might reasonably assume that the opposite effect would be the result, but it is not so. I consider that we gather quite as great a weight of fruit from our autumn crop as from our summer crop. The former crop continues right through September and October, and even into November when the weather is favourable. We have most to dread from the "London special," as the fog does more harm than an early frost; and when very severe, like it was last autumn, the foliage curls up, and the crop suffers as a consequence. In the country, however, this would not obtain. There the autumn raspberry may be grown, and that most successfully, wherever the summer kinds succeed well.

I strongly advise that more attention be paid to this crop. To say that the room cannot be afforded will scarcely hold good, for even a couple of rows will give a good return. This season, as a case in point, when we have not any too many of our usual choice dessert fruits for the table, these raspberries come in to fill a gap in "the nick of time," so to speak, whilst in the kitchen they are simply invaluable, and highly appreciated, so I am told.

Cultivation.

Cultivation does not in any material degree differ from that given to the summer-fruiting varieties. Where one will thrive there the other will succeed equally well. Our autumnals are grown now, as in 1903, on the same quarters. The soil has a tendency to be heavy just in this spot, yet it suits this fruit admirably. Every four or five years we lift at least half of the quarter, and thoroughly trench the ground fully three feet deep, and then replant from the same stock. In doing this we select the best canes, planting three or four in a clump at from two feet to three feet apart, with, in our case, as we are short of room to some extent, a distance of five feet between the rows. Another foot for the taller varieties would be better.

I prefer to do the replanting in the spring, when the canes are first pruned down to the ground, with only a few eyes left to each cane. During the latter part of the month of February, or early in March, we find a good time; later even than this will suffice. The first thing to do is to sort the canes as they are lifted, and lay all of them in by their heels, planting the most promising on the same ground again, or on fresh ground if needs be. The weaker stock will be useful as a reserve, should such be required.

When not transplanting I like to have the ground forked over lightly soon after pruning. Supposing a good dressing of farmyard or stable manure be applied when the ground is trenched for planting, then the following spring I would apply a fair proportion of an artificial compound—one that is suited to fruit production rather than to exuberant growth. The ground should be kept well stirred through the season, and if it be a hot, dry summer (as in 1911), a light mulching is most desirable.

I do not make it a practice to thin the growths, or to tie them up in any way, until the first week in August. By that time the growths of one row touch those of the next. At the time mentioned a few upright stakes are fixed, say, at ten feet apart. To these a transverse stake, or bamboo, is fixed, at from three to four feet from the ground. Then all the shoots that are showing for flower at the terminals are slung up to the cross stake, not in anywise tightly. Raffia does for this very well. All the shoots that do not show flower by that time are thinned out, only sufficient being left to make out the line, if needs be. By the end of the month (August) upright stakes, four inches by three inches, are driven in, and upon the tops of these, say, at six feet, cords are stretched as a support to the nets, which are then strained as tightly as it is safe to do so, and completely over the quarter and down the sides, so as to keep all birds out. For this protection I much prefer one-inch mesh light netting to any other, made, of course, on the square mesh, so as to cover in an equal manner. This is infinitely better, in my opinion, than any form of galvanised wire netting that can be selected. I have noted that after an early morning frost the raspberries under the netting have been safe, when outside the vegetation around has been white.

When the fruit has all been gathered the nets are, as a matter of course, taken off when quite dry; and there is nothing more to be done until pruning in the following spring, save keeping the ground clean of weeds.

Autumn-bearing raspberries are sometimes termed "perpetual," but this, in my experience, is quite a misnomer. One (summer sorts) bears on the old, or ripened wood, and the other (autumn sorts) upon the terminals of the green wood. To attempt a crop on both old and green growths is but to fail, under average conditions. There is one most commendable feature about the autumn raspberry, i.e., a good crop of fruit can be taken the same year as they are planted, and in less than seven months from planting. This should be noted by cultivators.

Jas. Hudson, V.M.H.

Gunnersbury House Gardens.

[When visiting the Gunnersbury House Gardens a few weeks since we were so much impressed by the remarkably fine crops of the autumn-fruiting raspberries, that we asked Mr. Hudson to give a sketch of the method by which he obtains such splendid varieties. This he readily consented to do, and we much appreciate his kindness.—Ed. "G.M."]

(To be continued.)

AN AVENUE OF SINGLE CORDON APPLE TREES.
In the kitchen garden with border of mauve aubrietias.

Sedum spectabile atropur. pureum.—Admirers of the Japanese Sedum spectabile, and they are numerous, would do well to obtain the variety atropurpureum where it is not already in their collection. It is a counterpart of the type except in the rich colour of its blossoms, which are conspicuous for a considerable distance.—S. W.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

DENDROBIUM PHALÆNOPSIS. — In private gardens where cut flowers are in demand for decorative purposes during the months of October, November, and December, Dendrobium Phalænopsis is one of the most serviceable orchids for this purpose. During late years this has been imported almost annually in large quantities, and plants have been procurable at a modest outlay, either through the importers or at the sale rooms. Those requiring this dendrobium in quantity should purchase imported plants. Not only is there a great amount of interest in first flowering imported plants, but, what is more important, such plants retain their native vigour, and flowers are not only produced from the growth developed, but many spikes proceed from the old pseudo-bulbs. There is also considerable variety, varying from pure white to rich purple colouring.

IN OR NEAR TOWNS.—I wish to warn all gardeners and amateurs against growing D. Phalænopsis in the immediate neighbourhood of London and other large towns where fogs are frequent in the autumn and winter. The least fog is sufficient to destroy all expanded flowers, and it is difficult to induce the flower buds of any of the plants to expand after the second week in October in fog-affected areas. With a pure atmosphere these disadvantages are not felt, and the plants are quite easy to grow.

GENERAL TREATMENT.—The treatment this dendrobium requires can usually be provided in the plant stove. Pots or shallow pans suffice, with very little potting compost about the roots. We find the plants do best when suspended near the roof glass. They commence to make their growth about the months of April and May, and potting is best attended to when the new growths first make their appearance. For potting compost use two parts fibrous peat, to one of sphagnum, with sufficient broken charcoal and sand added to render it porous. Make the material firm about the roots and base of the plants. From the time growth commences, until the spikes are cut or pass out of flower, the plants must have liberal treatment. During the summer they may be freely syringed overhead whenever the outside conditions permit. During their dormant season they must not be permitted to become unduly dry for any lengthened period. When the flowers have expanded they should be placed in a position where they do not get wet, and if they can be removed to a slightly drier atmosphere they last in perfection for several weeks.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

PERPETUAL - FLOWERING CARNATIONS.—The watering of these will require more than ordinary care during the next two or three months, and, although they will not require so much moisture at the roots as in the summer, they must not become too dry. Keep the flower buds and young growths neatly tied to the stakes, and let them have all the light possible. Should the glass outside become dirty through fogs, lose no time in cleaning it, as this would quickly cause the plants to become weak. Give plenty of fresh air during favourable weather, but avoid cold draughts. A minimum temperature of 45 or 50 degrees will suit them during the winter. Recently-rooted plants should be kept growing near the glass in a light structure. Shift them when the pots are full of roots, and attend to stopping and tying. Use artificial heat sparingly at all times. If not already done the young plants of Malmaisons must be shifted into 6-inch pots. Pot them firmly, using a compost of fibrous loam, naturally decayed leaf-soil, finely crushed brick-rubble, and coarse sand. Keep rather close until they have settled in the new soil, and give water with great care all through the winter months.

FREESIAS.—The earliest batch of these useful plants may now be given a slightly higher temperature. See that they are securely and neatly staked, and keep them growing quite near to the glass. As the pots become filled with roots a little stimulant may be afforded, increasing this in strength when the flower buds begin to develop. Attend to the staking of the later plants.

GENERAL WORK.—Cannas must now be induced to rest by gradually withholding water. When the foliage begins to die down the plants may be laid on their sides beneath a stage in a cool house, or packed closely together in a frostproof shed. Fuchsias may also be induced to rest by treating them similarly. Cinerarias should be placed in a cool house now, giving them a position near the glass. Place them, if possible, on a cool base of ashes or gravel. Use fire-heat only to keep them safe from frost, and give air abundantly on all favourable occasions. Keep a sharp look-out for the leaf grub; hand-picking is the surest way of eradicating this pest. Lightly fumigate the house at fortnightly intervals to keep the plants free from aphis. The blinds may now be removed from most of the houses and stored away in a dry place. See that they are quite dry before taking them down, and mark those which are unfit for another season.—E. HARRISS, Lockinge Gardens.

HARDY FRUITS.

GATHERING AND STORING.—By this date the greater part of our apples and pears will have been gathered from the trees, and carefully stored, with the exception of a few of the very latest kinds. Yorkshire Greening, Wellington, and Sturmer Pippin all keep much the best when left on the trees till very late. Keep the fruit room sweet and well ventilated; if a free circulation of air can be secured and the temperature kept somewhat dry and even, a superior flavour will result. Examine the fruits at intervals, remove any that have commenced to decay, but do not handle the fruits more than is possible. With us apples have this season coloured up well and grown to a good size. Pears should be kept in a slightly drier and warmer place than apples if good fruits are to be expected after Christmas. One of the best pears grown here to ripen at Christmas and in January is Nouvelle Fulvie, raised by M. Gregoire Nélis, of Joidoigne, Belgium, about the year 1854; and Josephine de Malines. The latter, in some seasons, keeps well till February.

PEACHES AND NECTARINES. — Any necessary root-lifting and pruning should be pushed forward, so that the roots may take to the fresh soil by the end of the season. I have lifted trees bodily early in October with every success, and also in March, but the latter date only in cases where it was really necessary, as the trees do not break away so freely or fruit well the first season after the operation. Young trees growing strongly should receive attention at once; take out a trench at a reasonable distance from the stem and deep enough to get well beneath the roots, then gradually work toward the tree and lift the roots entirely. Any damaged tips should be cut, the soil put into good order, and the roots replanted. If the borders were well prepared at the time of planting new soil need not be added, save a few shovelfuls of a moderately fine compost to shake well among the roots. For older trees soil should be renewed to give them a good chance to grow and fruit freely for many years to come. Peach trees crowded with useless wood will be all the better if somewhat thinned so as to allow the remaining shoots all the light possible. This mostly applies to trees that have not received the right attention during the growing season. Do not plant too many varieties that ripen about the same time, but endeavour, as far as is possible, to select the best kinds to keep up an unbroken supply for some weeks. In the north and more unfavourable parts late kinds must not be planted, as they rarely ripen satisfactorily in the open.

CUTTINGS of gooseberries and black and red currants may be prepared and planted for supplying plants to fill up gaps. In all gardens a few should be propagated annually of the most approved varieties, as they will take up very little space for the first season, and later on prove exceptionally useful. See that the cuttings rest firmly on a sandy base, and make them firm. Any trees to be planted should receive prompt attention.—H. MARKHAM, Wrotham Park Gardens.

THE KITCHEN GARDEN.

ASPARAGUS.—The permanent beds will now require attention; cut down the old growths close to the soil, clear the ground of all weeds and rubbish, and apply a thorough dressing of half-decayed farmyard manure. Soils deficient in potash will be materially improved by a good dressing of kainit, and this should be applied at the rate of 4 or 5oz. per square yard, previous to putting on the manure. The alley-ways should be marked out and the trimmings spread over the manure, making all tidy for the winter. Preparations for forcing will have to be considered where early asparagus is in demand. Though it can be brought forward quite easily under various conditions where heat can be employed, one of the most satisfactory methods is that of starting it on a mild hotbed made up in a deep pit, where, if required, artificial heat can be made use of during severe weather. When lifting roots do not expose them to the air longer than is absolutely necessary; take up and replant with the greatest possible speed. It is well to bear in mind that the quality is much improved when the asparagus is grown as near the glass as possible, therefore the beds should be made up accordingly. A thin layer of soil should first be spread over the hotbed material; on this place the roots, packing them as closely as possible. Cover the crowns with three or four inches of fine soil, and thoroughly water in with tepid water; if a moist atmosphere is maintained the new growths will soon appear. Fresh batches should be introduced according to requirements.

MUSHROOMS.—Beds which were spawned about six weeks ago are showing "buttons," and from now onwards will need to be examined frequently. If the heat of the mushroom house can be maintained at 60 degrees the litter can be removed. If the surface soil becomes dry, apply water at 80 degrees. The atmosphere of the house should be kept reasonably moist by damping the walls and paths; where successional beds are made up at regular intervals, the heat and moisture arising from them will render the atmosphere most suitable for the bearing beds. Prepare materials for forming other beds.

HERBS.—Some roots of tarragon and mint should be potted or boxed for forcing purposes and stood in cold frames for the present. A bed of chevril should be grown on a border and protected by hand-lights, or have a garden frame placed over it.—W. MESSENGER, Woolverstone Park Gardens.

EXHIBITIONS AND MEETINGS.

Ghent Autumn Show.

The last show of horticultural produce in connection with the Great International Exhibition was opened on Saturday last. The weather was fine, and there was an immense crowd of visitors waiting for the opening of the doors.

The judging was completed by midday, and at the luncheon offered to the jurors M. Alexis Callier presided, being supported by M. Ph. de Vilmorin, M. Helleputte, the Belgian Minister of Agriculture, and all the officials and members of the jury, many of whom had come from afar to fulfil their duties. France was particularly well represented, both in jurors and exhibitors. England was, on the contrary, rather poorly represented, there being only two jurors and three exhibitors.

CHRYSANTHEMUMS.

By far the most important exhibit in plants was that sent from Paris by the well-known firm of Messrs. Vilmorin, Andrieux, and Co. On a grass lawn of considerable extent there were cut out three large beds filled with bush-trained plants in this firm's usual style. At intervals were pyramids and trained specimens, the most curious being the Japanese square-shaped pyramids in which the flowers are trained in straight rows. The best blooms in the others comprised Miss Alice Byron, Alice Lemon, Vivi and Morel, Mrs. J. Neil, C. H. Totty, Rose Queen, Fron-Frou, Kara Dow, Safrano, and many novelties of the firm's raising. This group was in every respect one of the most important features of the show.

Novelties were not numerous or exceptional. M. Remy, successor to Calvat, sent about a score of varieties, set up in vases in fives. M. Herand also had a small collection. Mr. Thomas Stevenson, gardener to E. Mocatta, Esq., staged a superb lot of Japanese and single chrysanthemums of the highest order of merit, and was awarded the highest prize in his class by acclamation, with felicitations of the jury, who recommended an augmentation of the prize officially offered. At intervals there were huge stands containing massive bunches of colossal blooms alternating with vases of singles, the whole display most artistically lightened with maidenhair ferns, autumn foliage, and greenery. Specially fine were the blooms comprising eighteen grand Lady Talbots, Queen Mary, Hon. Mrs. Lopes, Alice Finch, Frank Payne, Alice Lemon, Mrs. G. Lloyd Wigg, Algernon Davis, Pockett's Crimson, and Bob Pulling. In all about 100 blooms in 36 varieties. The singles were fine, quite a revelation to many of the visitors, who had never seen anything of the like before. We noted Miss Mabel Booth, Celia, Ben MaChree, Mrs. Garnar, Cardinal (new), Portia, etc. Alongside Mr. Stevenson's fine group was one from Messrs. Wells and Co., of Merstham. They, too, set up a most artistic group of beautiful flowers in the Japanese and single section. Ferns and autumn foliage were also freely employed in this exhibit, making an effect quite different from most of the French and Belgian exhibits, which had a flattened appearance, much resembling the azalea displays in the spring show. Messrs. Wells had a fine novelty, Wm. Vert, a crimson Japanese of large size, that made a most effective show. There were also Mrs. Gilbert Drabble, Queen Mary, Mrs. Keith, Sunford, Mrs. R. Susford, Mme. Morel de Westgaver, Rose Queen, etc. Singles included Mensa, Elfrida, Celia, Altrincham Yellow, Sylvia Slade, Addie Mason, White Swan, and numerous others. They also staged a collection of carnations.

There was an excellent display by M. Firmis de Smet, a huge semi-circular group on one side of the hall exactly opposite a similar one from Mme. Morel de Westgaver. The former was awarded a Gold Medal value 250 francs, the latter a work of art. The lady's group had the finer flowers, and the depth of the group was considerable. We noted Wm. Turner, Mrs. J. Wells, Mrs. R. Susford, Mr. W. Mease, O. H. Broomhead, Tokio, Reginald Vallis, Vicar of Bray, Mrs. Coombs, Mm. Gustave Henry, but there were probably hundreds of other varieties, many of which were purely of foreign origin.

Messrs. Rivoire and Sons, of Lyons, sent a mixed collection of chrysanthemums and dahlias. From the same city M. André Charmet sent chrysanthemums and carnations. Other exhibitors whose plants and blooms must be passed over for want of space included Messrs. J. Chevalier, August Cornelis, Mme. Felix Burnaerts (a really nice group of good standard varieties), Victor Verellin and Sons, Robert Vandevelde (some good plants, each carrying six to eight blooms), Ad. de Schriver, Ed. Adam, and Leopold Burger, who put up a collection of the Caprice family.

A noble lot of fifty cut blooms of Mrs. Gilbert Drabble was staged by M. Pierre Degoes. The Van Houtte Establishment also showed a collection of dwarf plants in pots, bearing medium sized blooms in great variety; among them were Wm. Duckham, Wilfred Godfrey, Solange, Mary Mason, Excelda, etc. A curious group of about 400 cut blooms arranged in long lines was shown by M. Jules Collette, the variety being Alice Lemon.

The Society of Horticulture at Lille showed a large group of single blooms mingled with cocos, and edged with Asparagus plumosus. Nice flowers here were Sapho, Mary Mason, La Gracieuse, Mme. P. Radaelli, F. S. Vallis, Valerie Greenham, Mary Inglis, etc. A rather good exhibit of blooms, all of show quality, was put up by M. Paul Féron—Wm. Turner, Splendour, Mrs. R. Luxford, Mrs. D. Syme were among the best. Mme. Morel de Westgaver had some freely-flowered decorative Japanese in bush plants. A very large, flat group, containing many varieties, came from Messrs. Louis Sels and Co. A French firm, Messrs. Dubuis-on-Foubert, sent a fine lot of big Japanese; Thomas Lunt, F. S. Vallis, Wm. Turner, Reg. Vallis, Alec Payne, Mrs. Gilbert Drabble, Colonel Linel were only a few of the most attractive.

ORCHIDS.

Orchids formed quite an important part of the show, and some of the exhibits were of great extent. We can only mention a few of the leading exhibitors by name, such as Messrs. Sander, of Bruges, Jules Hye de Crom, Ch. Diebrich, Chas. Vuylsteke, Charlesworth and Co., Dr. G. Ballion, Emile Praet, René Behiels, Maurice Verdonck, Jean Van de Putte and Co., Th. Pauwels (a huge display), Firmin Lambeau, to all of whom prizes were awarded.

Other flowers were not staged in much variety. We noted lilacs by M. H. Graindorge, hydrangeas by Mr. Schatteman; a pretty exhibit in the floral decorations came from M. Van Houtte, wreaths of orchids, and chrysanthemums. Messrs. Cayeux and Leclerc showed cactus dahlias.

FRUIT AND VEGETABLES.

Fruit was largely shown by Mr. Nombloi-Bruneau, apples and pears, a substantial addition to the show. The Syndicat des Viticulteurs staged grapes, a nice lot, in pairs of bunches; we noted Gros Colmar, Gros Maroc, Gros d'Ore, Black Alicante, Muscat d'Alexandrie, Frankenthal, etc.

The P.L.M. Railway Company also had a collective group of fruit in baskets and semi-circular pyramids. M. Chevillot staged grapes; M. Victor Citelli, fruit.

Vegetables occupied a large portion of the space, and some of them were remarkable for the variety of the collections. Special mention should be made of the one staged by Messrs. Vilmorin, Andrieux, and Co., which was quite on a par with most of those we have seen at other Continental shows. The Vinderhoute Society of Gardeners, the P.L.M. Raily. Company (a collective group), the Syndicat des Agriculteurs Maraichers d'Avignon, and also of Aramon, were well represented in the vegetable section. Some came also from the Vilvorde Horticultural School, and elsewhere.

There were many other smaller exhibits of vegetables and of fruits. At the time of posting our report the official prize list had not been printed, and the awards, mostly medals, were, therefore, not obtainable.

Hereford Fruit and Chrysanthemum Society.

OCTOBER 22 and 23.

The annual show of this society was held in the Shire Hall, Hereford. Apples had fifty-five classes devoted to them, and formed the chief attraction, being staged in excellent condition, though there was a deficiency of colour as compared with some years. Vegetables, farm roots, grain, and hops were also largely shown, and made interesting features. Only six classes were provided for the chrysanthemums, but these, being vase classes, together with trade floral exhibits, gave colour, and thus improved the general effect. The familiar and kindly face of the late Mr. R. M. Whiting, of Oredenhill, was sadly missed, a fact that was feelingly alluded to at the luncheon by Mr. Powell, in proposing a vote of condolence to Mrs. Whiting, her sons and daughters. The late Mr. Whiting will be remembered as a successful exhibitor of hardy fruit at the leading shows.

APPLES.

In the class for a collection occupying 75 square feet, Mr. C. W. Powell, Warham Court, was the only exhibitor, but deservedly secured the first prize with a fine collection of large, clean fruit of leading varieties. For a collection in 40 square feet there were three lots staged. Mr. R. Stephens, gardener to Captain Clive, Whitfield, securing the lead with a meritorious exhibit, which included fine examples of Mère de Ménage, Gascoign's Seedling, Loddington Seedling, Blenheim Pippin, Warner's King, Striped Beaufin, Peasgood's Nonsuch, Bramley's Seedling, Hawthornden, Golden Noble, September Beauty, Adam's Pearmain, and Ribston, Allington, and Cox's

Orange Pippins; Mr. S. Stenhford, gardener to Mrs. Hill, Moreton Court, was a good second with a well-arranged collection of leading varieties. Five fine sets of twelve dishes of culinary varieties were arranged; Mr. Barker, gardener to F. Boddington, Esq., Burghill, was placed first with very large, clean examples of Bismark, Warner's King, Stirling Castle, Bramley's Seedling, Beauty of Kent, Lady Henniker, Golden Noble, Annie Elizabeth, Lane's Prince Albert, Golden Spire, Blenheim Pippin, and Newton Wonder; Mr. Kelly, gardener to Messrs. Getthing and Newton, Glewston Court, Ross, was a capital second with an almost equally good set, amongst which Emperor Alexander, Newton Wonder, Bramley's Seedling, Hambling's Seedling, and Cox's Pomona were noted. For eight dishes dessert varieties there were four competitors, each of which staged first-rate produce. Here again Mr. Barker took leading honours with excellent dishes of Ribston, Cox's Orange, and King of the Pippins, Adam's Pearmain, Court Pendu Plat, Worcester Pearmain, Charles Ross, and Rival; Mr. Kelly was again a close second.

There was strong competition in the single dish classes, and in these many of the best examples of the several kinds were found. Mr. Kelly took the lead for Blenheim Pippin, Bramley's Seedling, and Lane's Prince Albert; Captain Cox, Ashe Leigh, Ross, for Cox's Orange Pippin, Gascoign's Seedling, Newton Wonder, and King of the Pippins; Mr. Maiston, for Wellington; Mrs. Hill, for Peasgood's Nonsuch; Mr. Caddick, for Annie Elizabeth; Mr. Powell, for Lord Derby, Rival, and with May Queen for any new variety; Mr. J. Riley, for Allington Pippin; and Mr. Liddle, gardener to Sir J. Cotterell, for Warner's King. Mr. Kelly led with Stirling Castle for any early or midseason culinary variety; and Mr. A. G. Bunney with Mère de Ménage for any late culinary variety.

AMATEURS AND TENANT FARMERS.

In the class for eight culinary and four dessert varieties of apples, three capital sets were staged, Mr. Liddle securing the chief honour with fine, clean dishes of Striped Beaufin, Warner's King, Lord Derby, The Queen, Newton Wonder, Mère de Ménage, Blenheim Orange, Adam's Pearmain, Ribston Pippin, King of the Pippins, etc.; Mr. Bott, Breinton, was a close second with Stirling Castle, Annie Elizabeth, etc. Mr. Powell was the only exhibitor of six dishes, selected from sixteen specially named varieties, and he took the first prize with excellent fruits of Lord Hindlip, Rival, King Edward VII., King's Acre, Bountiful, Charles Ross, and James Grieve.

The three following classes were devoted to varieties suitable for market purposes. For eighteen dishes, twelve culinary, six dessert, there were three competitors, Mr. Kelly taking chief honours with fine examples of Beauty of Kent, Bramley's Seedling, Stirling Castle, Newton Wonder, Lane's Prince Albert, Cox's Orange Pippin, Charles Ross, Blenheim Orange, etc.; Mr. Bott second. Eight dishes of culinary varieties found Mr. Kelly again first with capital examples of Newton Wonder, Warner's King, Stirling Castle, Lane's Prince Albert, Peasgood's Annie Elizabeth, Cox's Pomona, and Bramley's Seedling; Mr. Powell was second with an almost equal production. For eight dishes of dessert varieties, chief honours were again secured by Mr. Kelly with a beautiful set of Rival, Charles Ross, Adam's Pearmain, Wealthy, Worcester Pearmain, Blenheim Orange, and King and Cox's Orange Pippins. Mr. Bott was placed second.

BOXES PACKED FOR MARKET.

Five classes were provided in this section, and the fruit in each box exhibited was firmly and otherwise well packed, though in some cases it was of better quality or better graded than in others. Each box was 28lbs. in weight. Captain Cox was placed first amongst five competitors with Newton Wonder; Mr. Kelly first amongst four competitors for Lane's Prince Albert; Captain Cox first for Cox's Orange Pippin; Mr. Kelly first for Bramley's Seedling; and Mr. Powell first for Blenheim Orange.

CHAMPION CLASSES.

Captain Cox was first for the best dish of dessert apples in the show with large, clean, and highly-coloured fruit of Cox's Orange Pippin; Mr. Liddle first for a dish of culinary apples, with perfect examples of Warner's King; Mr. Hallett, gardener to Mrs. Abbott, first for dessert pears, with a splendid dish of Marie Louise; and Mr. Sykes, gardener to Colonel Henry, Haffield, first for grapes, with a large, perfectly-finished bunch of Gros Maroc.

PEARS.

These were not staged in quantity, though the quality in most instances was decidedly good. There were two collections of twelve dishes, Mr. Parrott, gardener to A. W. Foster, Esq., Brockhampton Court, Ross, taking a decided lead with splendid dishes of Marie Louise, Emile d'Heyst, Doyenne du Comice, Pitmaston Duchess, Marie Louise d'Uccle, Easter Beurre, Durondeau, Glou Morceau, Beurre Bosc, Beurre Alexandre Lucas, Beurre Rance, and Beurre Superfin; the Rev. G. H. Devonport, Foxley, was the other exhibitor in this class. Many fine examples were found in the single dish classes.

COLLECTIONS OF FRUIT AND GRAPES.

Three collections of six dishes of dessert fruits were staged, Mr. Sykes being first with excellent Gros Maroc and fair Muscat of Alexandria grapes, very good Cox's Orange Pippin apples, and Pitmaston Duchess pears, a fine Royal Jubilee melon, and Brown Turkey figs; Mr. Liddle, who followed, had as his best dishes Doyenne du Comice pears, Cox's Orange Pippin apples, and Coe's Golden Drop plums.

Gros Colmar grapes were shown in good condition both by Mr. Liddle, who took the lead, and Mr. Tomeley, gardener to General Clive, who came second. With any other black variety, Mrs. Woodhouse was placed first with large, handsome bunches of Alicante; and Mr. Sykes second with Mrs. Pince. For white varieties there were four lots of Muscat of Alexandria staged, the best coming from Mr. Liddle, who had tapering, long, somewhat thin clusters, beautifully coloured, and with large berries.

TRADE EXHIBITS.

These were not numerous. The King's Acre Nurseries, Lim., staged about 100 dishes of excellent apples and pears, with a background of well-cropped fruit trees in pots. Mr. Wilson, Commercial Street, Hereford, put up a large exhibit of floral designs and plants; and Messrs. Young and Co., Cheltenham, had a fine display of carnations of leading varieties.

TABLE DECORATIONS.

Six tables were arranged, and that from Mrs. W. Spencer, Goodrich, who took chief honours, wis very tastefully executed, with a single bronze chrysanthemum as her chief subject, relieved with Asparagus plumosus, and a small-leaved smilax; Mrs. Offler was a good second, with Mary Richard chrysanthemum as her principal subject.

Royal Scottish Arboricultural Society.

ABERDEEN BRANCH.

The quarterly meeting of this society was held in the Marischal College, Aberdeen University. Mr. A. Forbes Irvine, of Drum, Aberdeenshire, presided over a large and representative assembly of landowners, factors, and foresters. After a number of new members had been admitted, the Chairman intimated that the subject for discussion at the meeting was "A Comparison of Home and Foreign Timber"—a very important one for all members of the branch.

Mr. Sydney J. Gammell, of Drumtochty and Countesswells, in opening the discussion, said it was really the users of timber who decided to what purposes foreign and home timber should be put. They had in this country examples of most of the trees grown in Continental countries as exotics, and some from foreign countries, and the distinctions which were drawn between the foreign classes of timber as it came into the market were not always an advantage to the timber grown in this country. They had to look into that question and see whether the criticisms were justified, and whether they could remove the difficulties which people asserted were present in the supply of home-grown timber. They should also endeavour to concentrate their energies on growing the species best suited for commercial uses, so as to provide a large supply. The most valuable structural timber was redwood. A good many people in this country did not appreciate that redwood was nothing more or less than Scottish pine. As regarded that class of timber, Scottish pine was fully equal to the best class of pine that could be imported. Its inherent qualities were strength, durability, and workableness, and in some parts of Scotland the timber grown could beat that from any other place. Other countries might grow straighter and longer timber, but he doubted if anything better could be produced as regarded quality than that on Deeside, say, at Ballochbuie. Although they had excellent specimens of timber in Scotland, when it came to commercial timber they could not compete with the foreign product. Home-grown timber was often seldom matured, soft at the heart, was knotty, and contained a good deal more sap than that of other countries.

The white wood in trade was the common spruce, the quality of which was not equal to the foreign timber. Sylvicultural methods of cultivating the spruce had been very much neglected in this country. Many people of high distinction maintained that the spruce could be planted almost anywhere in this country, and that it would succeed owing to the dampness of the climate. It would be a great help if experiments in timber growing were undertaken in the near future, and it would be better for those who used it. Good spruces could be grown in Scotland, and, he believed, would be very suitable for the pulp-making trade. With regard to prices, the price given for the home product was not by any means equal to that given for foreign timber. This might be due to quality, steadiness of supply, and the haphazard way in which the home supplies were sent to the market. For certain purposes he believed the quality of the home supplies was fully equal to that of foreign growth, and it was the duty of a society such as theirs to see that the quality of the home product was not prejudiced in the matter of price when compared with anything which came from another country.

Sir John Fleming, of Dalmuinzie, chief partner in the firm of a large timber business in Aberdeen and Dundee, remarked that in the early sixties wood merchants did a considerable trade in home products, and to-day he would much prefer to have timber from Scotland than from foreign lands. He contended that architects were the sole arbiters as to the kind of timber used in the construction of buildings, and said they required to be educated as to the advantages of the home material. At present the supply of home timber could not compete with that from abroad, but he believed that in the course of a couple of centuries of systematic sylviculture it would be possible to have a home supply that would do so. Sap was the bane of the home-grown fir. The nearer the trees were to the North Pole the less became the sap; and in the neighbourhood of the White Sea the trees had barely any sap at all. A quantity of seed from that district might be planted in Scotland, and the results noted. It was for the new Forestry Department in Scotland to reach the bottom of such matters, and they should start at once with a better system of afforestation. There were no finer hardwoods than the English oak, the elm, and the Scottish ash;

but it was quite impossible to obtain them in large quantities. Under proper conditions, and given good time, there was no reason why a large portion of the woods in this country should not supply timber for house building and house furnishing. Before that day came, however, there must be development on proper scientific lines.

Mr. Clark, forester to the Earl of Aberdeen on the Haddo House Estates, remarked that in Aberdeenshire there were specimens of the Scotch fir, the spruce, and the larch, as good as would ever be grown. He believed if the railway rates for timber transport were reduced that it would help the production of home timber. Mr. C. S. France, retired forester, Aberdeen, thought there was nothing to compare with the Scotch pine, and criticised the methods of planting in the past. Mr. John Rule, forester, Huntly, remarked that foreign timber was superior when a good length was required. If the home product was used there was much waste in cutting it up. Mr. Gammell, replying to the discussion, said there was nothing more foolish than the way in which Scotch pines had been planted broadcast throughout the country.

The Chairman, at the close of the discussion, said he thought they would be satisfied that the small quantity of the home product was a disadvantage when competing against foreign timber. If proprietors wanted commercial timber, then they would have to work on commercial lines; if they wanted cover for game, then let them have it.

A vote of thanks to the chairman, proposed by Sir John Fleming, brought the proceedings to a close.

Croydon Chrysanthemum Show.

This society is fortunate in being able to hold its show in the Central Baths Hall, Croydon, where there is ample room for exhibits and visitors, and where abundance of top light and high sidelight enables everyone to see the flowers at their best. In the old days the society had very poor accommodation, and often had to arrange exhibits in a series of rooms; the new order is distinctly the better.

The exhibition was a first-rate one, and competition throughout was keen; the flowers were of good size, fresh, and bright, and, as these were all staged in vases, the effect of the whole display was excellent. Fruit was well shown, and there were some fine vegetables, though this latter section of the show was not up to the usual standard. Groups and plants, too, are deserving of praise, and a few non-competitive groups lent additional interest.

CUT FLOWERS.

The competition for the Borough Challenge Cup is always fairly keen. The specification is eighteen blooms, distinct, staged in six big vases. There were seven competitors, so this class alone made a good show. The cup was won by Mr. A. Smith, gardener to Mdme. Shunder, Convent Gardens, Roehampton, whose fresh blooms were of good size and of fine colour, the best varieties being Mrs. A. T. Miller, Bryant's Beauty, Lady Talbot, Bob Pulling, Frances Row, Reg. Vallis, J. Surry, Eclipse, and F. J. Mar. Second prize fell to Messrs. Jas. Stredwick and Son, Silverhill Park, St. Leonards; and third to Mr. R. Warner, gardener to Mrs. Krauss, Ewell Grove, Ewell.

Mr. A. Smith (who, by the way, had a breakdown on his way to the show, and consequently had to stage his flowers very hurriedly) also secured first prize for ten Japanese blooms, in two or more vases, and here he had fine examples of Lady Talbot, Reg. Vallis, Master David, White Queen, Mrs. G. Lloyd Wigg, and Master James. There were five competitors, and the other prizes went to Mr. J. S. Kelly, gardener to H.R.H. the Duchess of Albany, Claremont, Esher; and Mr. C. Fox, Linden Gardens, Tunbridge Wells.

Ten incurved blooms, in vases, brought out five competitors, and premier place was filled by Mr. T. Finch, gardener to G. H. Fisher, Esq., Downs View, Kenley, who set up capital specimens of Clara Wells, Mrs. G. Denyer, and Buttercup; Mr. A. G. Osmond, gardener to C. H. Wells, Esq., Springfields, Avenue Road, South Norwood, second with William Biddle and C. H. Curtis; Mr. G. Fisher, gardener to C. Lazenby, Esq., Oakfield Gardens, South Eden Park, Beckenham, third, with C. H. Curtis and Buttercup.

The local cup, presented by Mr. and Mrs. Allen, for the best fifteen Japanese blooms, in vases, fell to Mr. H. Green, gardener to A. McAlister, Esq., 28, Park Hill Rise, for excellent blooms of Rose Pockett, R. W. Witty, W. Mease, Coronation, F. Green, etc.; Mr. R. Gladwell, a good second; and Mr. T. Finch third; six competitors. Mr. Green is a new competitor; last year Mr. Gladwell was the winner. Out of eight competitors, Mr. L. Gooch, gardener to Wickham Jones, Esq., Frocester, South Norwood, was placed first for ten Japanese blooms, and he showed Master James and Mrs. G. Drabble in fine style; Mr. E. A. Kembry, gardener to J. Tidy, Esq., Park House, South Norwood, second; and Mr. A. G. Osmond, gardener to C. H. Wells, Esq., Springfield, South Norwood, third.

In the local amateurs' division, great interest centres in the competition for the Epps Challenge Cup, value fifteen guineas; ten Japanese blooms, in two vases, are required. There were six competitors, and the fortunate one was Mr. F. M. Parris, 56, Selsdon Road, Croydon, who scored with fresh examples of Master David, Mrs. G. Drabble, and Mrs. C. Penford; Mr. F. Oldham, 48, Cannington Road, Croydon, second; and Mr. W. Philpot, 57, Church Street, Croydon, third. In the same section Mr. Louis White, Braemar Avenue, Thornton Heath, came first for five Japanese blooms; and Mr. C. C. Hunt, Stroud Road, Woodside, South Norwood, led for five incurved blooms with Romance.

Single chrysanthemums are always very well shown at Croydon, and on this occasion there were four competitors in the open class for three vases of these flowers. Mr. T. Fisher was an easy first with splendid disbudded flowers of Mensa, Bronze Pagram, and Merstham Gem, etc.; Mr. W. R. Warner, gardener to Mrs. Krauss, Ewell, second; and Mr. T. Finch third.

Mr. Howarth was a capital first for three vases of mixed single blooms, with suitable foliage; Mr. T. Finch second; and Mr. A. Martin, Shirley Lodge, Shirley, third; the five competitors made up a goodly display. Mr. A. Head, gardener to Mrs. Fisher Watson, Lancing House, Coombe Road led for one vase of single flowers in a class where there were over a dozen entries.

FRUITS AND VEGETABLES.

Apples were splendidly staged, the competition being very keen throughout. In the open class for nine dishes, six culinary and three dessert, Mr. J. S. Kelly was first prize-winner with highly-coloured, clean, weighty examples of Gloria Mundi, Peasgood's Nonsuch, Hawthornden, Cox's Pomona Annie Elizabeth, Gascoyne's Scarlet, King of the Pippins, Allington Pippin, and Cox's Orange Pippin, the latter a grand dish. Mr. A. Smith, Roehampton, came second, and Mr. G. Martin, gardener to J. R. Brougham, Esq., Bridge House, Wallington, third. There were seven entries. In the open class for six dishes of pears, Mr. Kelly was again first with Pitmaston Duchess, Triomphe de Jodoigne, Fondante de Thirriott, Beurre Alexander Lucas, Beurre Diel, and Doyenne du Comice; Mr. Lintott second, and Mr. W. R. Warner third.

In the local classes, Mr. A. Jeal, gardener to N. Waterall, Esq., Waddon Lodge, Waddon, led for three dishes of dessert apples among seven competitors; and Mr. G. Maslin scored for three dishes of culinary apples with first-rate Bramley's Seedling, Warner's King, and Peasgood's Nonsuch, among six competitors. For three dishes of pears Mr. R. Gladwell, gardener to A. Gosheron, Esq., South Norwood, was first.

Mr. Lintott was the only exhibitor of black grapes (Alicante), and Mr. W. Colyer the only exhibitor of white grapes (Muscat of Alexandria); the former was awarded a first, and the latter a second prize.

Vegetables were scarcely so fine as usual at Croydon, nor so numerous as on many previous occasions, and the falling off is due to the dry weather acting on the light soil in so many parts of the Croydon district. For a collection of six kinds, Mr. A. Jeal was first with celery, cauliflowers, tomatoes, potatoes, sprouts, and leeks in good form; Mr. T. Finch second, and Mr. E. Puxted, gardener to H. E. Alder, Esq., Bromley Hillside, Croydon, third.

For nine kinds of vegetables, Mr. W. Lintott proved the most successful competitor, and he staged celery, fine parsnips, self-protecting broccoli, leeks, carrots, Ailsa Craig onions, Factor potatoes, and Brussels sprouts; Mr. Jeal second.

GROUPS OF PLANTS.

Five competitors came forward in the class for a group of chrysanthemums, and each had to stage on the tiered sides of the Baths Hall. From a spectacular point of view this arrangement was a good one, but it did not permit of close inspection of the flowers. Mr. W. Howarth was first, and he had easily the best flowers, though the colouring of the varieties was dull; Mr. W. Colyer second; and Mr. A. Edgerton, gardener to W. Valder, Esq., Beechwood, Cosham Park Avenue, third; each with bright displays.

The groups of miscellaneous plants were poor; Mr. T. H. West, gardener to H. R. Dickenson, Esq., Rydal Mount, Croham Park Avenue, was first prizewinner; and Mr. Puxted second; but in each case the exhibitor seemed to have been bothered by the tiered staging on which the plants had to be arranged.

Of winter-flowering begonias there was but one exhibitor, and Mr. G. Fisher was deservedly awarded first prize for his fine half-dozen specimens of B. Gloire de Lorraine, all shapely and freely-flowered. Mr. W. Lintott, gardener to Sir Walpole Greenwell, Bart., Marden Park, Caterham, came first for nine table plants, and staged some particularly elegant and highly-coloured crotons; Mr. T. Colyer, gardener to A. H. Allen, Esq., Wandle Court, Beddington, third.

Mr. T. Finch was awarded a first prize for three pots of single-flowering chrysanthemums; he was the only competitor, and showed freely-flowered specimens of Miss M. Pope, Caterham Bronze, and Mary Richardson.

FLORAL DECORATION.

The best table decoration was one of rose-pink and lilac chrysanthemums, pompon, and quilled varieties, prettily associated with slender sprays of coloured berberis, maple, and spiræa foliage, and a few oak and croton leaves—a very distinct design, and well worthy of the leading award. It was arranged by Mrs. A. Robinson, Norhyrst, Carshalton; Miss Bashfield second with golden and bronze flowers; and Mrs. Hyem, The Fourth House, Banstead Road, Carshalton, third, with single flowers.

A charming basket of yellow, single, and incurved, and crimson decorative chrysanthemums, associated with red oak and croton foliage, secured for Mrs. A. Robinson, Norhyrst, Carshalton, the premier award in the basket class; Miss Marsh, Holmsdale Road, South Norwood, second, with a rather heavy arrangement; and Miss Bashford, Barrow Hedges Farm, Carshalton, third.

NON-COMPETITIVE.

Messrs. W. Wells and Co., Merstham, displayed a considerable number of new chrysanthemums, and among these their Daily Mail and William Vert, already described in these columns, were outstanding Japanese sorts. Margaret Sargent, a soft, golden-yellow sport from Meusa, was a splendid new

single. Messrs. W. Cutbush and Son, Highgate, brought a display of perpetual carnations, greenhouse plants, and dahlias. Messrs. H. Cannell and Sons, Eynsford, were represented by a splendid lot of apples, large and bright fruits, admirably set up.

Mr. Thos. Butcher, The Nurseries, South Norwood, decorated the platform with chrysanthemums and palms, and filled a table with bold and striking floral designs, a golden harp of chrysanthemums being a special feature. Messrs. J. Cheal and Sons, Crawley, contributed a small collection of apples, and Dr. Jackson put up seventy dishes of culinary and dessert apples, all grown in his garden at Torridge, Brigstock Road, Thornton Heath, which was once an old gravel pit.

Horticultural Club.

On Tuesday, the 21st instant, this club opened its winter series of dinners at the Hotel Windsor, Mr. A. Worsley taking the chair, and some sixty members and guests being present. As usual, after the dinner a lecture was given, and on this occasion an exceptionally interesting one was delivered by Professor W. B. Bottomley, B.A., on "The Effect of Soluble Humates on Nitrogen Fixation and Plant Growth," illustrated by numerous lantern slides and living plants showing the good effect of manuring with peat treated with bacterial infusions, as described by the lecturer.

Samples of the raw peat in a normal brown, flaky, hard condition, and of the prepared material as a very dark, almost black, substance, of a very soft and loose, fibry character, were exhibited, together with various infusions containing the active bacterial principles with which it is permeated. This prepared material, when combined with ordinary soil, undoubtedly produces potent stimulative effect upon root and foliage production, as was exemplified by a large number of trial plants, such as fuchsias, hippeastrums, radishes, geraniums, tomatoes, ferns, and other plants. The plants were, in many instances, three or four times the size of those grown in non-fertilised soil after being selected at the outset as of as exactly equal size and constitution as could be chosen.

A number of these trials were made at Kew under the supervision and actual personal selection and cultivation of Mr. W. Watson, the Curator, who was present, and testified to this effect. As the tendency of manures to stimulate root and foliar growth is generally associated with a comparative diminution in the inflorescence, it is noteworthy that in these instances, where flowering plants were employed, they all flowered profusely. In the subsequent discussion, in which Messrs. W. Watson, A. Worsley, Dr. Voelcker, Prof. Keeble, and others took part, the evidence produced by Prof. Bottomley of the stimulative effect of his material was fully accepted, but it was pointed out and recognised by Prof. Bottomley himself that it still remained an entirely open question as to how this came about, and what was really the actual stimulating factor, since as yet we were but on the edge of a vast field of research, to which the facts ascertained were merely pointers. The question of cost, for instance, when put for comparison between the cost of farmyard manures or artificial ones, could not, as Prof. Bottomley allowed, be as yet determined.

Laboratory experiments with plants in pots might be very convincing as regards principles, but the position was very different when it became agriculturally a question of large acreages subjected to the normal climatical conditions, and with possibly great variation in the constituents and conditions of the soil. To the horticulturist, on the other hand, it was recognised that great benefit might be afforded in the near future, especially as the whole of the cultural tests illustrated on the screen and by the actual living plants shown, had been the outcome of only eight weeks' culture in ordinary greenhouses. Professor Keeble pointed out in particular how complex were the chemical and mechanical factors in the problem of ascertaining the actual causes of the results obtained, and challenged the accuracy of the term "nitrogen fixation" as being the determined cause of the robust growth. He, however, as did the meeting generally, fully recognised the great value of Prof. Bottomley's work, and a very hearty vote of thanks was accorded him for his exposition of the results.

North of Scotland Horticultural Association.

The usual monthly meeting of the members of this association was held in the Botany Classroom, Aberdeen University Buildings. There was a good attendance, and Mr. Lockart, president, occupied the chair. In the course of an interesting address, the President outlined the work devolving upon each member in the endeavour to make the meetings of the association instructive and educative, and to create an interest in all branches of horticulture. He called on every member who had it within his power to contribute his quota towards making the meetings as useful and instructive as possible. Mr. C. S. France, Aberdeen, then gave a much-enjoyed description of the visit of the members of the association to Aberlour Orphanage and Gardens, Dufftown, in the month of August last.

Mr. P. Innes, assistant gardener, Dunecht House, Aberdeenshire, Lord Cowdray's Scottish seat, then read a paper on "Vegetable Culture," in which were given the results of practical experience in growing the various kinds of vegetables which can be successfully cultivated in the North of Scotland. Mr. William Smith, gardener to Lord Sempill, Fintray House, Aberdeenshire, showed a collection of dahlias, the finely-developed blooms being greatly admired. Mr. William Ironside, gardener to Sir David Stewart, Banchory House, Aberdeen, exhibited a fine collection of onions and carrots, for which he was awarded a Horticultural Certificate. He had also a fine specimen artemisia, for which he was given an Award of Merit. Mr. W. Henderson, Aberdeen, showed a greatly admired collection of begonia blooms. The usual votes of thanks brought to a close a very pleasant and instructive evening.

Croydon Gardeners' Society.

At this society's fortnightly meeting held on Tuesday last an interesting lecture was given by Mr. M .E. Mills, Coombe House Gardens, and Mr. T. Ray Willis, St. Augustine's Avenue, the title of the lecture beiug "Hardy Orchids for the Flower Garden." The subject of hardy orchids appealed to Mr. Willis, who is an amateur of repute in this district, and in his gardens he has taken up the cultivation of about ten of the species, and some twenty varieties, and it was to these he confined his lecture, which, with the help of Mr. Mills, enabled the members to acquire considerable knowledge of the subject. To attempt to naturalise these plants one has to study position and soils for their well-being. Mr. Willis, in making up his orchid bed, has chosen the north end of his garden, under the shade of a standard laburnum, lilacs, and double cherries. As a surface covering to the soil he grows the golden-leaved creeping jenny, saxifragas, violas, and wild strawberry. This covering is a protection in the winter, and helps to check evaporation in the hot, dry mouths of the summer. The soil is made up principally of loam, with the addition of leaf-mould and peat for some, and, generally speaking, chalk or limestone abounding throughout. The cultivator must be guided by the kinds he is growing as regards the exact soil to use, and for those plants that require lime a small boulder should be placed near the roots, placing this as naturally as can be to add to the charm of the garden. When planting the tubers these should not be placed at a greater depth than three to four inches, and around the roots sprinkle coarse sand.

A very detailed description was gives of the different kinds and varieties enumerated; this included the formation of the flower, colour, character of foliage and root, locality where usually found, perfume, and the necessary soil to grow in. Mr. Willis was also able to give records of the time of flowering, and the heights attained.

The audience were thoroughly interested in the lecture, and conveyed the heartiest thanks to the lecturers at the termination of their discourse.

Exhibits of fruit, vegetables, and flowers were well shown by Messrs. Doddridge, E. Mann, T. H. West, G. Cole, O. Jeal, and Playford, and a vote of thanks was accorded them.

Broughty Ferry Horticultural Association.

The ordinary monthly meeting was held on the 21st inst., the President, Mr. James Bethel, being in the chair. Mr. James Staward, St. Fort Gardens, Newport, was the lecturer, and had for his subject, "Growing Tree Carnations." In dealing exhaustively with the subject, the lecturer demonstrated his enthusiasm and practical ability, and many helpful hints were gleaned by the very large audience, which were attracted by the popularity of the subject and form of the lecturer. A lengthy and somewhat animated discussion followed, after which the lecturer was highly complimented on his practical demonstration of facts.

The monthly prize was awarded to Mr. George Masson, Aystree Gardens, who showed a very fine specimen Begonia Gloire de Lorraine. The only other exhibit was that from the lecturer, consisting of cut blooms of tree carnations and neat, well-grown specimens growing in 2½in., 4in., and 5in. pots.

Kent Commercial Fruit Show.

(Continued from page 818.)

SUNDRIES.

The exhibits of machinery, implements, and chemical preparations of direct importance to fruit-growers were numerous, and of varied character. Local firms came out in force, and several of the best known manufacturers from a distance had also made special endeavour to bring before the notice of fruit-growers the spraying machines, fluids, grease bands, and fertilisers, which they prepare on scientific lines for the use of the farmer and gardener. The Four Oaks Spraying Machine Company, Sutton Coldfield, had a double range of sprayers, pumps, and nozzles, which they claim will meet every requirement, and certainly some of their devices are capable of some remarkable things in the way of distributing chemical mixtures over the surface of large or small fruit trees. Large machines suitable for either fruit farmers or hop growers were shown by Messrs. W. Weeks and Son, Lim., Maidstone, who also had the "Digit" grading apparatus, an implement that is capable of sorting fruits in six different sizes. This machine we described fully in our report of last year's show. Messrs. Voss and Co., Millwall, London, E., showed spray fluids, winter washes, and other chemical preparations of great utility; and Mr. M. Herrod, Wisbech, showed a variety of his remedies and preventatives for diseases and fungoid pests.

Messrs. E. A. White, Lim., Paddock Wood, Kent, showed "Abol" syringes and spraying machines, and the "Abol" fruit wash, which has proved itself equal to combating the psylla and other pests that affect fruits in the early spring. Their stand was made attractive by a display of fruit grown on the Paddock Wood Farms that had been assisted in development by the "Abol" specialities. Messrs. Drake and Fletcher, Maidstone, were large exhibitors of spraying machines, and also had a very useful-looking grading machine for apples, potatoes, and other products of garden and farm. Messrs. Haynes Bros., Lim., Maidstone, specialised in packing presses, tools, and syringes, their hydronettes being useful, fine-rosed syringes fixable to a barrel of prepared fluid.

BOULTON & PAUL, LTD., HORTICULTURAL BUILDERS, Norwich.

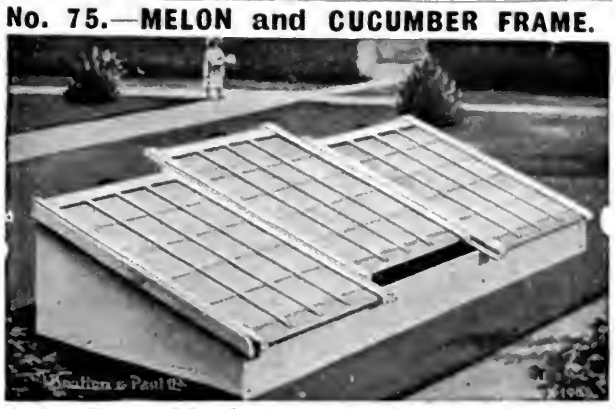
ATTRACTIVE. PRACTICAL GLASS HOUSES.

Ladies and Gentlemen waited upon by appointment.

CARRIAGE PAID on orders of 40/- value to most Goods Stations in England.

CARNATION HOUSES A SPECIALITY. HEATING APPARATUS installed in COUNTRY HOUSES, HORTICULTURAL & PUBLIC BUILDINGS.

No. 75.—MELON and CUCUMBER FRAME.



4 ft. by 6 ft. ... £2 0 0 | 8 ft. by 6 ft. ... £3 0 0
Painted three coats. Glazed with 21oz. Glass.

No. 77.—VIOLET FRAME, 6ft. by 4ft. Similar to No. 75, with Two Lights... £1 15 0

SEND FOR ILLUSTRATED CATALOGUES.

Every part of these Houses is thoroughly well made, painted three coats, GLAZED AT OUR WORKS WITH 21oz. GLASS and CARRIAGE PAID.

No. 49A.—Span, 10ft. by 8ft. £11 10 0
No. 47A.—Lean-to, 10ft. by 7ft. £9 10 0

All parts are numbered ready for easy re-erection by any handy man.

ANSWERS TO CORRESPONDENTS.

BORAX AS A MANURE. — Hibernia writes: "I would like to add to your reply to 'A. M. B., Wavertree,' re borax, that the sodium-loving plants are the ones that will derive the most benefit from a dressing of it as a manure. It is a compound, and in the following proportions: Sodium, 2; boron, 4; oxygen, 7. Boron is of no use to plants, but sodium is valuable as a food to carrots, parsnips, asparagus, and all seaside subjects. As chemicals are powerful agents where affinity is strong, it is always best to err on the safe side by giving rather less than more of them at a dressing. This is specially desirable where the young rootlets are near the surface of the ground, and are likely to get the chemicals in a crude state. I have found that 1½oz. of chemicals to the square yard is the maximum quantity to apply in cases of that kind. When the roots are some distance under the surface the chemicals have an opportunity of changing their character in passing through the soil and becoming less caustic in their properties, and a strong dose will have no bad effect.

RUST ON ROSE LEAVES.—A. J. A., Chardwar: I am enclosing rose leaves for your inspection. Can you tell me the cause of the injury, and means to combat the disease? Our soil is rather heavy, and wet during the winter months.—The roses are suffering from an attack of rose rust (Phragmidium subcorticatum), a fungus that is frequently found on wild as well as on cultivated roses. This fungus is a very difficult one to eradicate because it produces three different kinds of fruits. The two summer forms appear in summer and follow each other, and in these cases evidence of the disease is found on the orange-coloured and powdery patches upon wood and leaves. These coloured patches are generally small, but sometimes several of them run together and so cover a large portion of a leaflet. When the wood is attacked the patches may be an inch long, and they frequently distort the growth, and after the disappearance of the rust it is no uncommon thing to find the affected portion become an open cankerous wound, which not only reduces the vitality of the plant, but opens the door to all sorts of fungus diseases. In the autumn the third form of fruiting occurs, and takes the form of tiny black points adhering to the underside of the leaves. In the specimens sent the leaflets are all freely studded with these black points, which are really clusters of microscopic winter spores. Such spores remain on the decaying foliage all the winter, and in spring they produce secondary spores, which attack the new growths and foliage, and so carry on the disease. It is a matter of the first importance that all fading and falling leaves should be gathered and burned, and infected leaves on the bushes should be removed and burned. The thoroughness with which this work is carried out will largely determine the amount of disease that will appear next spring and summer. It should be added that the black clusters of winter spores are not produced on the wood, only on the leaves. When the foliage is expanding next spring spray the bushes with a solution of sulphide of potassium.

MILDEW ON CHRYSANTHEMUMS.—G. M. K., Ilfracombe: I am sending a few chrysanthemum leaves infected with a mildew-like fungus. Please say how best to get rid of the trouble on plants under glass.—Chrysanthemum mildew (Oidium chrysanthemi) sometimes causes a great deal of harm to chrysanthemums crowded together under glass, as it attacks both leaves and flowers. If there is room to do so, and the weather is fine, spray with a solution of sulphide of potassium; otherwise dust all the foliage freely with flowers of sulphur. By means of the heating apparatus and ventilators secure as dry and airy an atmosphere as possible.

CLUB-ROOT DISEASE IN BRUSSELS SPROUTS.—F. M. P., Pinner: I had a very fine bed of Brussels sprouts, but since the beginning of August they have steadily gone off. I find, on examination, that the plants are club-rooted. Can you, through your valuable paper, give me the cause of, and also the remedy for, this disease?—Club-root disease is one of the most disgusting as well as one of the most destructive of diseases which attack garden and field crops. The roots of affected plants become swollen, warted, and clubbed, and presently decay and emit a most offensive odour. The cabbage family suffers most from the attacks of this fungus, but other families of the Order cruciferæ are not exempt from its evil influence. The scientific name of the fungus is Plasmodiophora brassicæ, and other popular titles, beside that of club-root, are Aubury and finger-and-toe. Where the disease has occurred no brassica crop should be planted or sown upon the same site for a year or two, and every care must be taken that when the infected soil is being cultivated none of it is carried to other parts of the garden on boots, wheels, tools, etc. Quick lime well worked into the soil at the rate of 75 bushels per acre will destroy the fungus germs in the soil, and it has been stated that 35 bushels per acre will arrest the disease in its early stages. In gardens a common plan is to use fresh gas-lime, from the gas works; spread it freely on the infected plot, break it down finely, and thoroughly mix it with the soil as the work of digging or trenching proceeds. Land so treated should be left rough for the rest of the winter, as gas-lime will kill all vegetation it comes in contact with, hence the need for care if fruit trees or other plants surround the plot. A point to be remembered is that every plant infected with club-root should be pulled up and burned at once, and on no account be left to rot, thrown on the rubbish heap, or fed to pigs, or the plague will be spread far and wide. Put fresh lime into each hole as plants are withdrawn, and, finally, when the crop has been cleared, deal with the land as suggested.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

C. F. G., Watford.—1, Arbutus Unedo; 2, Iris stylosa; 3, Schizostylis coccinea.

M. E. R., Sidcup.—1, Fittonia argyroneura Pearcei; 2, Dracæna Sanderiana; 3, Saintpaulia ionantha.

T. C. H., Canterbury.—1, Hypericum calycinum; 2, Euonymus europæus; 3, Plumbago rosea; 4, Epipendrum vitellinum majus.

F. C. F., Towcester.—1, Abies Nordmanniana; 2, Ardisia crenulata; 3, Euphorbia splendens; 4, Calanthe Veitchi; 5, Hibiscus Cooperi.

D. B., Dydale. — The Miltonia flower represents a very fine form of M. candida, with the lip coloured instead of white; M. candida varies a little in colour, but we have never before seen a variety with such a pronounced violet-purple lip. The cœlogyne we do not recognise, but it is closely allied to C. fuliginosa.

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, GARDENERS' MAGAZINE, as advised in the notice at the head of "Answers to Correspondents."

M., Broome.—1, not recognised, probably a local variety; 2, Queen.

T. C. H., Sheffield.—1, Beurre Diel; 2, probably Beurre Clairgeau; 3, Golden Noble.

B. H. A., Ruabon.—1, Emperor Alexander; 2, Chelmsford Wonder; 3, Warner's King.

W. J. W., Ledbury. — 1, Alfriston; 2, Lane's Prince Albert; 3, Mabbott's Pearmain; 4, Gravenstein.

F. C. F., Towcester.—1, Egremont Russet; 2, Tyler's Kernel; 3, Bismarck; 4, Warner's King; 5, Ribston Pippin.

E. G., Hertford.—1, Blenheim Pippin; 2, Yellow Ingestre; 3, Bramley's Seedling; 4, Dumelow's Seedling; 5, not recognised; 6, Pitmaston Duchess.

OBITUARY.

MR. JOHN BURR.

Intimation has just been received in Aberdeenshire, of which county he was a native, of the death of Mr. John Burr, a well-known citizen of San Fernando, California. Mr. Burr was born at the Schoolhouse, Lethenty, Fyvie, Aberdeenshire, his father being for long schoolmaster of the parish. Receiving a capital education, Mr. Burr chose for his calling that of gardener, and served his apprenticeship at Duff House, Banffshire, then owned by the late Duke of Fife, but which, along with its fine demesne, was handed over a few years ago by his Grace to the towns of Banff and Macduff as a public gift to the communities. Thereafter he pursued his avocation in England for some time, and then emigrated to America. There for some years he worked as a landscape gardener, and in 1884 he purchased a large ranch in Tulare County, where he raised vines and wheat. Three years later he went to San Fernando, and acquired a large amount of land, amounting to hundreds of acres, which, assisted by his sons, he laid out as a fruit farm. He also retained a large interest in orange groves in Tulare County. A keen business man, Mr. Burr was of an energetic and resolute nature, which did much to account for his rise to a position of affluence and repute in his adopted country. He took a great interest in public affairs, and was for four years Sheriff of Los Angeles County. Four years ago Mr. Burr paid a visit to his native land, where he spent a long holiday renewing the friendships of his earlier years. On returning to California, he had the misfortune to receive serious injuries as the result of being thrown from his motor car. Mr. Burr never recovered from the effects of his accident. He was 64 years of age.

NEW BOOK.

SCHOOL GARDENING.

By Laurence B. Hyde, B.A. (Messrs. W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London, E.C.) Price 1s. net.

The remarkable extension of school gardening in Great Britain within recent years has given rise to a strong demand for information on the best methods of cultivating gardens associated with school work, and on the means by which a knowledge of the gardening art can be readily imparted to children attending elementary and other schools. This demand has resulted in the publication of a considerable number of handbooks of a somewhat variable character. In come cases the writers have shown a full acquaintance with educational methods, but have lacked the practical knowledge of gardening so essential to success. On the other hand, the authors have in several instances evinced a good knowledge of the practice of horticulture, and a weakness in dealing with educational methods. In the handbook now before us, which has been prepared under the supervision of Mr. T. W. Sanders, F.L.S., the cultural and educational aspects are equally balanced, and show that the author is fully acquainted with the best methods of procedure in the cropping and general management of school gardens, and possesses in a marked degree the ability of imparting knowledge to children.

The book may well be described as an all-round guide to its subject, and the author has, by means of clear text and helpful diagrams, described the various aspects of practical work connected with a school garden in such a manner as to enable the pupil to readily understand them. A concise calendar of work for each month of the year is given, and there is also a series of typical questions for the use of teachers, and these two features can hardly fail to prove of much value to them. The section devoted to the cultivation of annuals, bulbs, and other flowering and ornamental plants in the house will be found of much value to both pupils and teachers. The book is admirably produced, inexpensive, and so brightly and clearly written, and so sound in every particular, that we have no hesitation in recommending it as a valuable aid in teaching the practice and principles of gardening to children.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

TUESDAY, November 4.—Royal Horticultural Society; Committees meet at 12 o'clock; Lecture at 3 p.m. on "Formal Garden Design" by Mr. Edward White; Scientific Committee at 4 o'clock.
West of England Chrysanthemum Show; two days.
National Amateur Gardeners' Association.
Scottish Horticultural Association.
Plymouth Chrysanthemum Show; two days.
Leicester Chrysanthemum Show; two days.
WEDNESDAY, November 5.—National Chrysanthemum Society's Exhibition at the Crystal Palace; three days.
Putney and Wandsworth Chrysanthemum Show; two days.
Bath Chrysanthemum Show; two days.
Wargrave Chrysanthemum Show.
THURSDAY, November 6.—Colchester Autumn Show.
Forest Gate Chrysanthemum Show; three days.
Devon and Exeter Chrysanthemum Show; two days.
Cambridge Autumn Show.
Linnean Society meets.
Bury St. Edmund's Chrysanthemum Show.
Coventry Chrysanthemum Show.
FRIDAY, November 7.—Altrincham Chrysanthemum Show; two days.
Windsor Chrysanthemum Show.
SATURDAY, November 8.—Horsforth Chrysanthemum Show.
Formby Chrysanthemum Show.

CATALOGUES RECEIVED.

AMOS PERRY, HARDY PLANT FARM, ENFIELD.—The trade list issued by this firm should be in the hands of all who retail hardy plants.

ELISHA J. HICKS, HURST, TWYFORD, BERKS.—A boldly-printed descriptive catalogue of roses, and guide to cultivation. Mr. Hicks' successes in 1913 make a lengthy list.

WM. CUTBUSH AND SONS, HIGHGATE AND BARNET.—This firm cultivates roses on a large scale at the Barnet nurseries, and the catalogue of those flowers, now issued, is a most interesting one and admirably arranged.

LAXTON BROTHERS, BEDFORD.—A catalogue of fruit trees and roses, and one that is particularly interesting because of the new fruits listed and described; these include two new apples, a peach, two plums, a red currant, and an autumn-fruiting raspberry.

THE PENNICK CO., DELGANY, NEAR DUBLIN.—This closely-printed catalogue lists a very great variety of flowering shrubs, forest and fruit trees, and alpine and herbaceous plants, and it is interspersed throughout with apt quotations from well-known writers.

ARTHUR R. BROWN, LIM., WYCHALL NURSERIES, KING'S NORTON.—"Carnation Brown" is quite right in calling his new issue a "Catalogue de Luxe of Carnations and Roses." Thoroughly well got-up, the catalogue proves vastly interesting and informative, as it contains much that is of value to exhibitors and to the ordinary grower, while in addition to excellent descriptions there are beautiful coloured plates of Becky Sharp, My Fancy, Wyatt, and a houseful of carnations in bloom.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

The Glory of Autumn.

Although the autumnal hues of the leafage of the many beautiful deciduous trees and shrubs that contribute to the interest and charm of the garden and park have been less brilliant this season than in some previous years that are readily recalled to mind, they have been, and in some cases still are, so rich and beautiful as to fully justify their designation as the "glory of autumn." Just now, in gardens that are large enough to afford space for the adequate representation of a considerable proportion of the choicer kinds, the colour effects produced by the varied leaf tints are still of great beauty—so beautiful indeed as to surprise not a few of those who have failed to devote a proper share of attention to this important aspect of arborescent and ligneous vegetation. In such gardens where the selection has been made by those who are fully acquainted with the leaf colourings, as well as with the stature and form of the kinds most valuable in the creation of park and garden scenery, we shall see great masses of foliage ranging in colour from, on the one hand, the palest yellow to the richest gold, and on the other from light red and bronze to the most brilliant scarlet and the deepest crimson. Not alone are the leaves in their diversity of colouring used by Nature in the creation of autumn pictures so distinct from those painted by the hand of man, and, moreover, so wondrously beautiful as to fill the mind with feelings of the highest admiration. There are a considerable number of trees and shrubs that have barks not less valuable in garden scenery than are the leaves of many of the choicest kinds, some of the most noteworthy of these being found among the dogwoods and the willows. We were reminded the other day of the plenitude and the immense value of the trees and shrubs remarkable for the autumnal hues of their leaves and bark when enjoying a leisurely walk through the pleasure grounds of Aldenham House, the residence of the Hon. Vicary Gibbs, which are quite unique, both as regards their area and the remarkable representation of arborescent and ligneous vegetation within their boundaries. Well might it have been said, as one enjoyed the series of charming colour schemes of the autumn:

"A thousand tints,
Which Flora, dressed in all her pride of bloom
Could scarcely equal, decorates the grove."

MR. COURTENEY PAGE.

In these famous gardens, not only are kinds, well-nigh innumerable, planted singly or in groups, and allowed to grow more or less naturally, but some of the more distinct are arranged in masses and grown under what is popularly known as the "cutting down system." This system is very simple and, briefly stated, consists in cutting the growths back at the winter pruning to within a few inches of the surface of the soil and allowing the resulting shoots to grow unchecked during the following summer. Under this course of procedure the growth is strong, the leaves attain a large size, and the colouring is remarkable for its intensity. The large masses of the golden form of the Canadian poplar that are so conspicuous in the grounds throughout the summer and autumn may be mentioned as a striking proof of the fine effects that may be obtained in the latter season by means of the cutting-down process. In the earlier stages of development the ample leafage charms by its softness of colour; when the growth approaches completeness the rich golden hue contributes much to the effect of the scene of which the groups form a part by the striking contrast of colour it affords. It is, however, as the season of the fall of the leaf approaches that we have the most conclusive proof of the value of the golden Canadian poplar in garden scenery, for then the characteristic colouring is so highly developed that the large leaves assume so bright a hue as to shine like burnished gold under the influence of the subdued rays of the autumnal sun. In the Aldenham House Gardens full advantage is taken of the aid the hardy herbaceous plants are able to render in the production of autumn effects, and stems and leaves that assume more or less attractive hues on the completion of their functions are allowed to remain until they decay, instead of being cleared away in "tidying-up," in accordance with orthodox practice. A considerable number of kinds are most useful, more especially a considerable proportion of the flags and reeds that are generally planted on the margins of ponds, lakes, and other areas of ornamental water in the garden. These contribute liberally to the russets and browns so pleasing in association with both rich green and brightly-variegated leafage. Ornamental water forms, as is well known to many of our readers, an important feature of the gardens referred to, and the masses of leaves in their various shades of brown afford a series of most pleasing contrasts, and fully justify the departure from the practice which has so long obtained. The more liberal planting of trees and shrubs that, by reason of the attractiveness of leaf colouring in autumn, are able to contribute liberally to the charm of the garden at a decidedly dull period of the year, can be all the more strongly recommended from the fact that they rank high among the kinds that are deservedly held in high estimation for the beauty of their leaves or

flowers during the spring and summer months. This is necessarily a point of considerable importance, and not less interesting to many readers will be the intimation that the best of them may be obtained at the prices which govern the sale of nursery stock of an ordinary character. It would be interesting and useful to pass under review the finest of the trees and shrubs that have leafage which takes on effective colouring in the autumn, but it would require more space than can now be spared. We cannot, indeed, attempt to do more than suggest a few kinds that are of special value. From those which have leaves that change to some shade of red we would advise our readers to select Acers circinatum, Ginnala, Henryi, rubrum eriocarpum, and palmatum—the last-named in variety. Berberis Thunbergi has scarlet leaves, and is unsurpassed by other small-growing shrubs, and is only rivalled by some of the Ghent azaleas, Cratægus punctata and pruniflora, Liquidamber styraciflua, pyrus in great variety; Parrotia jacquemontana, Quercus coccinea, Rhus cotinus, R. typhina, and R. typhina lacinata, one of the most elegant of the trees of small growth. Several of the ornamental vines are unsurpassed in colouring, especially good being Vitis armata, V. Coignetiæ, and V .Henryi. The trees that assume a yellow hue include the horse-chestnut, Acer pseudo-platanus, Cerasus padus bracteosa, Cratægus coccinea maxima, C. pentagyna, Ginkro biloba, Liriodendrons chinensis and tulipiferum, Pavia flavia, Populus canadensis aurea and Spiræa opulifolia. There are several kinds well worth planting for the distinct colours of their bark, but the most useful of all are the dogwoods, such as Cornus alba, C. alba Späthi, and the willows, Salix glauca, S. purpurea, and S. vitellina, and they should have first attention from the planter.

Mr. Courteney Page, whose home is at Earlsdoms, Ridgeway, Enfield, has acquired a considerable reputation as an amateur rosarian who does the whole of the work in connection with his roses from A to Z, and from January to December. He plants and buds his own stocks, and all the flowers he has exhibited are from plants so raised by him. Mr. Courteney Page is a very keen amateur gardener, but during the past five and twenty years he has devoted attention chiefly to roses, and has achieved a large measure of success in his hobby. Plenty of people are willing to win cups and other prizes, but few are ready to devote their time and ability to the work of the society which provides the prizes. In this connection Mr. Courteney Page sets a good example, for he is a member of the Council of the National Rose Society, and is a hard-working member of the Exhibitions Committee and the General Purposes Committee of that ever-extending and otherwise flourishing association of rose growers, and takes an active part in its work.

Dahlia Trials at Duffryn, 1914.—The trial of dahlias, from a garden decorative point of view, carried out this year in the gardens of Reginald Cory, Esq., at Duffryn, has proved a genuine success, and in consideration of this, and desiring to still further encourage raisers to devote particular attention to producing varieties best adapted to garden decoration, Mr. Cory felt the desirability of holding a further trial next year, and, after putting his views before the Council of the Royal Horticultural Society and the National Dahlia Society, and being assured of their willingness to co-operate with him, as they did this year, he has decided to hold a trial in 1914 of seedlings not in commerce, and any varieties offered for the first time in 1914. These will be grown, and judged, and reported on in exactly the same way, and, as far as possible, by the same individuals as in 1913. Three plants of each variety should be sent, carriage paid, to Reginald Cory, Esq., Duffryn, near Cardiff, if sent by post; or labelled per G.W.R. to Ely Station, near Cardiff, if sent by rail. For various considerations it has been decided that only rooted cuttings must be sent; and those who intend participating in the trials are particularly requested to send them as early as possible in the year, in order that they may be grown on to the best advantage before planting out. Mr. Cory kindly offers a £5 5s. cup to be awarded for the most meritorious plant in the trials, and the Council of the Royal Horticultural Society will give any other award they think fit.

Variability and Sportiveness of Lilium Leafage.—From Hillside, Ricketts Hill, Tatsfield, Surrey, Mr. J. Sidney Martin writes: "It would be interesting to know from Mr. C. R. Scarse Dickins whether every bulbil taken from the sportive lilium had grown to leafage or not. It would be natural to expect that some would have kept true to the other part of the plant. I do not know Lilium Sargentiæ or Lilium myrcophyllum, but should think it likely that the sport leaves were the smaller ones. However, the size of the sport leaves might serve Mr. Scarse Dickins as a guide in coming to some conclusion as to its cause. If the leaf be smaller he might look for a decreased energy or sap flow at the roots of the parent sportive plant; or if larger leaves increase of energy. For not only will leaves of plants vary by every adjustment, but a plant is capable of giving the flower of that variety which preceded it. This I have proved."

Public Park for Boquhan, Stirling.—Mr. Stephen Mitchell, of Boquhan, Kippen, has presented a pretty park to the inhabitants of Kippen, and great gratification is expressed by them at the announcement, which was made the other day. The park is very conveniently situated, and adds another to the several handsome benefactions made by Mr. Mitchell to the people of Kippen.

Two-days' Rose Show at Saltaire.—It was announced at the annual dinner of the Saltaire, Shipley, and District Rose Society, that the committee was proposing to hold a two-day rose show at Saltaire in 1914. No dates have been given. It has often been stated that a rose show is not worth looking at on the second day, therefore the Saltaire Society's experiment will be looked forward to with great interest.

Proliferous and Seedless Pears.—Mr. A. E. Bunyard sent to the recent meeting of the R.H.S. Scientific Committee a pear, evidently from a summer flower, from the apex of which a stem proceeded, bearing in its turn an apical fruit. Mr. F. J. Chittenden also showed somewhat similar fruits from Wisley, in one case bearing three buds at the distal end. Mr. Chittenden remarked that many, but not all, pears produced from summer flowers, which were particularly numerous in the past season, were seedless, and showed examples in support of his statements. He had found, too, that the fruits borne when foreign pollen was prevented from reaching the stigmas were as a rule seedless, and in a few cases, when the seeds had begun to form, they had reached but a small size, and were infertile. He showed fruits of the variety Conference, and these, like Durondeau and Hacon's Incomparable, were quite seedless and had no developed core.

A Great Scheme to Beautify Paris.—Beautiful though it is, Paris lags behind several other great cities, London and Berlin, for instance, in the matter of the size and number of her public parks and open spaces. To rectify this, Mons. Delanney, Prefect of the Seine, has put forward a remarkable scheme, which, in brief, means the removal of large blocks of houses from the St. Lazare Station, the Halles, and in many neighbouring streets, so as to provide open spaces in these central quarters. But drastic as this proposal is, the rest of the scheme is even more interesting, and consists of providing a chain of avenues and pleasure grounds round the city, following the lines of the twenty forts, and linking these together. As many of these forts are as large as a good-sized park, this scheme is both bold and splendid. It is stated that such a scheme, carried to completion, would enrich Paris and its suburbs to the extent of about 17,000 acres, and the gay city would then possess 5 per cent. more open space than our own Metropolitan county. If the scheme is carried into effect, Paris would become the finest garden city in the world.

Kniphofia multiflora, a native of Natal, is a particularly late-flowering species, and, therefore, rarely does itself justice in this country except in very favoured localities. At Kew it is frequently spoiled by the frosts and rains of autumn, but this year it has been favoured, and there are sixty spikes in a round bed in front of the Orchid Houses. The whole inflorescence rises from three feet to five and a-half feet, and the spike proper ranges from fifteen to twenty inches in length. Kniphofia multiflora is not so showy as K. Tysoni, K. John Benary, and other gorgeous kinds, but it is very distinct and interesting. The small, crowded flowers are white, tinted pale green, and the prominent filaments are white, tipped with yellow anthers. Such an opportunity of seeing this rare kniphofia in good condition is seldom afforded in the Metropolitan district.

Alterations in the Rock Garden, Kew.—Advantage is being taken of the present open weather to proceed speedily with the work of alteration and renovation in the Rock Garden at Kew. Certain sections have been dealt with in recent years, and the plants have shown their appreciation of the new conditions. Work has now begun on the section from the path leading to the orchid houses, along to the end of the Rock Garden, on the right-hand side, going southwards. The slopes will be very easy, thus providing wider and larger spaces for plant colonies than a steeper design would permit. In one place, however, there will be a greater elevation than previously, consisting of two eminences, with an intervening valley. This arrangement will afford varying degrees of light and shelter suited to various subjects.

Southampton Royal Horticultural Society. — The exhibitions arranged by this society for 1914 are as follows: Rose Show, July 1, at South Stoneham Park; Summer Show, including carnations, July 21 and 22, at Royal Pier; Autumn Show, November 1, 3, and 4.

NATIONAL CHRYSANTHEMUM SOCIETY'S EXHIBITION.

The exhibition of chrysanthemums held by the National Chrysanthemum Society at the Crystal Palace, on Guy Fawkes and following days, was scarcely so extensive as some of its predecessors, so far as the competitive classes were concerned, but the show, as a whole, was well up to the average in extent and quality. In the larger classes there was a good competition, but there seemed to be a falling off in the amateurs' section. The decorative classes were well filled, and the vases of blooms were excellent.

MR. NORMAN DAVIS' GOLD MEDAL CHRYSANTHEMUMS AT THE CRYSTAL PALACE.

Awarded the N.C.S. Gold Medal and the Special Gold Medal offered by Messrs. Clay and Son, Stratford, for the best non-competitive display in the exhibition.

The attendance was larger than usual on the first day; no fewer than sixty-four novelties were placed before the Floral Committee, and nine First-Class Certificates and three Commendations were granted.

GREAT VASE CLASS.

The first prize of £9 for the best dozen vases of Japanese blooms, three blooms in a vase, was won by Mr. A. Chandler, gardener to Arthur James, Esq., Coton House, Rugby, with capital flowers of Thos. Lunt, Alice Lemon, His Majesty, Mrs. G. Drabble, Eclipse, Lady Talbot, Reg. Vallis, W. Turner, Marie Louise, Frances Jolliffe, Mrs. Gee, and F. S. Vallis, the latter very fine. Second prize fell to Mr. H. R. Farmer, gardener to the Marquis of Bute, Cardiff Castle, Cardiff, whose best flowers were F. S. Vallis, Miss A. C. Roope, Wm. Turner, W. Mease, and Lady Talbot; Mr. Thos. Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, Addlestone, third. There were five entries, so the class itself made a good display.

Mr. H. R. Farmer annexed the chief award for a dozen vases of incurved blooms, representing as many varieties, three blooms of each; his varieties were G. F. Evans, G. W. Matthews, Madame G. Denyer, F. Trestrian, Romance, Pantia Ralli, May Phillips, Mrs. J. Hygate, Le Peyron, Clara Wells, Mrs. P. N. Wiseman, and Embleme Poitevine; second award fell to Mr. G. Hunt, Ashtead Park Gardens, Epsom; and third to Mr. T. J. Broom, gardener to Miss Langworthy, Gay's House, Holyport.

HOLMES MEMORIAL CUP CLASSES.

The Holmes Memorial Cup for the best forty-eight Japanese blooms was won by Mr. A. Chandler, Coton House Gardens, Rugby, with a good stand that was scarcely up to Mr. Chandler's best efforts; the best flowers were of His Majesty, Mrs. Drabble, Hon. Mrs. Lopes, H. E. Converse, Mary Farsworth, Rose Queen, F. S. Vallis, Queen Mary, Bob Pulling, Kara Dow, Frances Jolliffe, and Lady Talbot. Mr. Thos. Stevenson, Woburn Place Gardens, a close second with a very bright-coloured and even set; and Mr. G. Hunt, gardener to Pantia Ralli, Esq., Ashtead Park, Epsom, third.

There were four competitors for the Holmes Memorial Challenge Cup for thirty-six incurved blooms, on boards, and here Mr. Hunt came first, and showed, among others, big specimens of Mrs. P. N. Wiseman, Clara Wells, Lady Isabel, Edwin Thorp, Embleme Poitevine, Mrs. H. J. Jones, Le Peyron, C. H. Curtis, Souv. de Wm. Clibran, Fred. Palmer, and Calypso; Mr. H. R. Farmer was a good second, and Mr. T. J. Broom third.

JAPANESE BLOOMS.

Mr. H. C. Gardner, Ruxley Lodge, Claygate, won Sir Albert Rollit's prize for the best twenty-four Japanese blooms, distinct, with a very even set of good flowers of Kara Dow, Alice Lemon, Frances Joliffe, Amber Queen, December Gold, W. Turner, F. S. Vallis, and His Majesty. There were nine competitors, and second prize fell to Mr. Thomas Beeson, gardener to W. Newton Mappin, Esq., Headley Park, Epsom, who had a wonderful Bob Pulling; third to Mr. J. Simon, gardener to W. W. Mann, Esq., Ravenswood, Bexley; and fourth to Mr. Thomas Stevenson.

The best dozen Japanese blooms, arranged with foliage and plants, were from Mr. G. Mileham, gardener to A. T. Miller, Esq., Emlyn House, Leatherhead; and second award fell to Mr. A. Winter, gardener to E. Mainwaring, Esq., Elm Lodge, College Road, Dulwich. Mr. Sargent, gardener to G. L. Wigg, Esq., Rockshaw, Merstham, scored in the class for one bloom of either Queen Mary, W. Turner, or Mrs. Drabble, and did so with Queen Mary, which was also the variety that won second place for Mr. H. C. Gardner.

Mr. Farmer was first for a vase of three white Japanese blooms with William Turner in fine form; Mr. H. C. Gardner, gardener to Lord Foley, Ruxley Lodge, Claygate, second; and Mr. P. Ladds, Swanley Junction, third. In the yellow class Mr. H. Woolman, Sandy Hill Nursery, Shirley, Birmingham, scored a first with Miss A. C. Roope; Mr. H. R. Farmer second with Lady Talbot; and

Mr. H. C. Gardner third with F. S. Vallis. Mr. Gardner led in the "any other colour" class with three grand flowers of His Majesty; Mr. H. R. Farmer second with Mrs. A. E. Tickle; and Mr. Woolman third with His Majesty.

Messrs. Cragg, Harrison, and Cragg, Heston, annexed first prize for a dozen market bunches of disbudded flowers, twelve blooms to a bunch; their varieties were Miss O. Dumsday, Freda Bedford, Mrs. W. A. Read, Yellow Moneymaker, Hortus Tolousanus, Batchelor's White, Crimson King, J. W. Stevens, Black Prince, Romance, Bronze McNeice, and Mrs. Buckler; a capital display.

INCURVED, SINGLE, AND OTHER VARIETIES.

Mr. T. G. Bealing, Bassett, Southampton, led for six incurved blooms, one variety, with enormous examples of Clara Wells; Mr. G. Mileham, gardener to A. T. Miller, Esq., Emlyn House, Leatherhead, second, with Buttercup; and Mr. Farmer third with Clara Wells; six entries. Mr. H. R. Farmer was a good first for a dozen incurved blooms, and was followed in order by Mr. G. Hunt and Mr. T. J. Broom.

The best table of single varieties was one arranged by Mr. Philip Ladds, Swanley Junction; the flowers were splendid, fresh, and on stout stems, but it was a great pity Mr. Ladds did not label the varieties; Mr. W. Heath, gardener to Sir Samuel Gooch, Bart., Hylands Park, Chelmsford, a good second; and Mr. H. Lloyd, gardener to Capt. C. Wiener, Ewell Castle, Ewell, third. There were seven entries in this class, and in each competitor had to fill a table 8ft. by 3ft. The class was a most successful one. C. E. Shea, Esq., offered a silver rose bowl as first prize in this class.

A superb set of eight vases of single varieties won Messrs. Cragg, Harrison, and Cragg's prize quite easily for Mr. E. Mills, gardener to Frank Lloyd, Esq., Coombe House, Croydon; he had wonderful examples of Mensa, Yellow Pagram, Sandown Radiance, Caledonia, White Pagram, and Bronze Pagram; there was only one prize offered, but there were seven competitors.

Five pairs of bunches of pompon varieties formed a pretty class, and Mr. F. Fitzwater, gardener to C. Urban, Esq., Bushey Lodge, Teddington, was placed first; Mr. G. Bowyer, gardener to P. Dawson, Esq., Maybourne. Laurie Park, Sydenham, second; and Mr. A. R. Robertson, gardener to F. J. Yarrow, Esq., St. John's Wood, N.W., third.

Mr Fitzwater was easily first for six vases of pompons, and he showed beautiful rounded blooms of well-known varieties; Mr. J. W. Hussey, Bouverie House, Exeter, second; and Mr. T. J. Broom third. For anemone pompons the awards fell to Mr. Fitzwater and Mr. T. J. Broom respectively. For large anemones Mr. T. J. Broom scored with big examples of Mdme. C. Lebosqz, Mrs. Heneage, Miss A. Lowe, Mrs. H. Claud, Marguerite, Soleville, and Mrs. Shimmings; Mr. E. Libbeter, gardener to Dr. Codd, Holmwood Lodge, Bromley, Kent, second; and Mr. W. Passey, gardener to C. Douglas Clarke, Esq., Achray, Shortlands, third.

GROUPS.

There were two exhibitors in the class for a floral display arranged on a circular space of 200 square feet; the best was an effective effort on the part of Mr. R. B. Leech, gardener to J. C. Eno, Esq., Woodhall, Dulwich. There was a large triangular, table-topped mirror in the middle of the group. On top of this were baskets and vases of single blooms, surmounted by a palm. Mr. Leech arranged this fine exhibit so that it was really three groups, each having a mirror background. Crimson and golden Japanese, decorative and single chrysanthemums were freely used with crotons, palms, and ferns in two of the sections; while in the other rosy lilac, blush, and white varieties were used to produce a distinct effect. Mr. W. Howe, gardener to Lady Tate, Park Hill, Streatham, came second with an excellent but more formal group.

AFFILIATED SOCIETIES.

The affiliated societies' class was this year for a dozen bunches of cut chrysanthemums, and the premier award fell to the Finchley Chrysanthemum Society, which put up capital pompon, anemone, single, Japanese, and incurved varieties, but, forgetting the educational value of such an exhibit, omitted to label the varieties.

DECORATIVE CLASSES.

First prize for a dinner table decoration of chrysanthemums was awarded to Mrs. W. C. Roelink, 94, Markhouse Avenue, Walthamstow, for a bright combination of yellow and light orange flowers associated with croton foliage and light sprays of asparagus; the upper part of the design was very weak. There were nine entries, and second prize went to Mr. A. W. Trossell, gardener to H. Attenborough, Esq., The Avenue, Beckenham, for a rich design in orange, bronze, and yellow flowers; Mr. T. W. Stevens, gardener to W. A. Stone, Esq., Donnington, Sydenham, third. In the other class for a table decoration, yellow and bronze flowers excluded, Mr. R. F. Felton, Hanover Square, led with rather large and heavy blooms of green, red, and lilac varieties, very deftly arranged, and with tiny silvery baskets of blooms depending from the centrepiece; Mrs. A. R. Bide, Highlands, Farnham, second; and Mrs. A. Robinson, Norhyrst, Carshalton, third.

Mrs. A. Robinson scored for a basket of chrysanthemums with bronze and yellow flowers associated with berberis, oak, and spiræa sprays; Mrs. Duquesnoy, Thornton Heath, second, with rosy and lilac flowers; Mrs. A. Brill, Southdown Avenue, Brighton, third; six entries.

There were no fewer than ten competitors in the class for a vase of single chrysanthemums, and here Mr. D. B. Crane, Highgate (whose vase we illustrate), was first with a bold, large, and beautiful arrangement of white, yellow, and crimson flowers, very cleverly grouped with asparagus sprays and croton leaves; Mr. Thomas Stevenson was a close second, and Mr. W. Dennis, Wood Hall Gardens, Dulwich, third.

AMATEURS.

In the amateurs' classes there were many excellent exhibits. Mr. T. W. Stevens, gardener to W. H. Stone, Esq., Laurie Park, Sydenham, scored for a dozen Japanese blooms; and Mr. Dyer, gardener to E. Wood, Esq., The Tyrol, Upper Norwood, scored for a dozen incurved blooms. Mr. Loo Thomson, Ailsa Craig, Formby, led the way for six bunches of singles with first-rate flowers of Yellow Pagram, Edith Pagram, Sussex Yellow, Ideality, etc.

In a second class for a dozen Japanese blooms Mr. W. Gooding, Four Elms, Edenbridge, was a capital first; Mr. A. F. Tofield, Chandlersford, second; and Mr. W. F. Bennett, Westcliff-on-Sea, third. Mr. Tofield was first also for another dozen incurved blooms, and Mr. J. Vanstone, Hollymead, Tulse Hill, scored for six Japanese blooms with capital flowers.

Mr. W. Passey, Shortlands, led for a vase of five Japanese blooms, with fine flowers of Reginald Vallis, Mr. T. W. Stevens coming second with Mrs. E. A. Tickle.

(Continued on page 851.)

A BEAUTIFUL VASE OF SINGLE CHRYSANTHEMUMS.

Arranged by Mr. D. B. Crane, Highgate, and awarded first prize, in keen competition, at the Crystal Palace.

NEW PLANTS AND FLOWERS.

CATTLEYA GRANIRIS.

A very distinct hybrid derived from C. granulosa and C. Iris. It has the erect growth of its parents, and, as shown, carried a pair of flowers. The broad petals and narrower sepals are light bronze, suffused with orange, while the wide open lip is soft purplish-crimson. A.M., R.H.S., October 21. C. J. Phillips, Esq., The Glebe, Sevenoaks.

CATTLEYA EMPRESS FREDERICK VAR. AVID CLIFTON.

A particularly beautiful form of the lovely hybrid between C. Mossiæ and C. Dowiana aurea. The large flower is white with a broad lip, coloured white, gold, and soft purple. A.M., R.H.S., October 21. Pantia Ralli, Esq., Ashstead Park, Leatherhead.

SOPHRO-LÆLIA CATTLEYA LACONIA.

A sturdy-growing little plant, which carried three fair sized blooms. The sepals and petals are deep reddish old rose, and the somewhat small lip is rich ruby-purple. The parents of this hybrid are Lælia-cattleya callistoglossa and Sophro-lælia heatonense. A.M., R.H.S., October 21. Messrs. Charlesworth and Co., Haywards Heath.

ONCIDIUM VARICOSUM WESTONBIRT VAR.

This very beautiful variety of a well-known and popular orchid is a particularly large one, and the wide lip is wholly of a bright, light shade of yellow, without the red-brown spots sometimes seen at the base of the lip. A.M., R.H.S., October 21. Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury.

ODONTOGLOSSUM VIVIEN.

Very much like a fine O. crispum, this hybrid of unrecorded parentage belongs probably to the eximium group. The large flowers are finely formed, white, with a tinge of purple here and there. On the petals there is a central red-purple area and a few spots and blotches of a similar colour occur on the sepals. A.M., R.H.S., October 21. Sir George Holford, Westonbirt, Tetbury.

CYPRIPEDIUM QUEEN ALEXANDRA.

This is a very large-flowered hybrid, and its parents were stated to be C. Lathamianum and C. Charlesworthi. Of fine form and substance as well as of fine size, the flower is most effective. Dorsal-sepal white with a bright purple base; petals tawny-green lined with purple, and lip of similar colour. A.M., R.H.S., October 21. W. R. Lee, Esq., Plumpton Hall, Heywood.

CARNATION CINDERELLA.

A distinct and beautiful perpetual-flowering variety. The flowers are large, the petals well developed without being too densely packed, smooth-edged, and of a heliotrope or blue-mauve shade, with splashes and flakes of bright red showing conspicuously. Slightly fragrant and with a first-rate calyx and stem, this should prove a popular variety. A.M., R.H.S., October 21. Messrs. George Fairbairn and Sons, Botcherby, Carlisle.

CHRYSANTHEMUMS.

Mrs. R. C. Pulling. — An easily-grown, large-flowering, incurved Japanese variety. The blooms are rounded and of fine substance, composed of curling as well as incurving florets. The colour is bright yellow, with a tinge of green. A.M., R.H.S., October 21. Messrs. H. J. Jones, Lim., Ryecroft Nursery, Lewisham.

Rosamund.—A very large and handsome Japanese variety with broad, reflexing florets that incurve a little at the tips. The colour is a rich and bright shade of old rose with a silvery-buff reverse. Section II., sub-section 1, a. F.C.C., N.C.S., October 27. Mr. Norman Davis, Framfield, Sussex.

Mabel.—A beautiful single variety of excellent shape, the regular, broad florets recurving a little at the tips. The colour is deep rose-red or rosy-amaranth, with a narrow white zone round the dull yellow disc. Commendation, N.C.S., October 27. Mr. G. Mileham, Emlyn Gardens, Leatherhead.

T. Barnes. — A fine decorative single variety, with stout stems. The flowers are large, and there are several rows of florets, the inner row a trifle shorter than the rest. The colour is a splendid shade of bright ruby, and there is a very narrow white zone round the neat yellow disc. Section V., sub-section 2, a. F.C.C., N.C.S., October 27. Mr. G. Mileham, Emlyn Gardens, Leatherhead.

Irene Clark.—A large-flowered single with slender but fairly stiff stems. The broad florets reflex a little at the tips, and are regularly arranged to form a shapely bloom. Colour, rich canary-yellow. Section V., sub-section 2, a. Commendation, October 27. Mr. G. Mileham, Emlyn Gardens, Leatherhead.

Orlando.—A capital large-flowered single variety, with medium sized florets, very closely arranged, and forming a very substantial bloom, borne on stiff stems above excellent leafage. Colour, rich canary-yellow. Section V., sub-section 2. a. F.C.C., N.C.S. Messrs. Cragg, Harrison, and Cragg, Heston, Hounslow.

Max.—A most attractive single, with very large flowers and fine stems and foliage. It has several rows of florets, but in colour is very near Merstham Jewel, the shade being described as bright golden bronze, with yellow zone and tips. Section V., sub-section 2, a. F.C.C., N.C.S., October 27. Messrs. Cragg, Harrison, and Cragg, Heston, Hounslow.

Jessica.—A real beauty. A very large single variety, with blooms fully six inches across without any trace of coarseness or lack of substance. There are three rows of florets, and these stand clear of each other at the tips. The colour, a rich shade of bright chestnut, with a narrow golden zone round the disc, and yellow tips. Section V., sub-section 2. a. F.C.C., N.C.S., October 27. Messrs. Cragg, Harrison, and Cragg, Heston, Hounslow.

W. Fawcett.—A lovely single of fair size, and a very free grower. It has good stems and foliage. The flowers are shapely and elegant, and the colour is buff-apricot, a

CARNATION CINDERELLA.

Flowers large, colour bright heliotrope, flaked with bright red. A.M., R.H.S., October 21. Messrs. G. Fairbairn and Sons, Botcherby, Carlisle.

distinct and new shade. Section V., sub-section 2, a. Commendation, N.C.S., October 27. Mr. L. Lawrence, Shoreham, near Sevenoaks.

L. Lawrence.—A big and very substantial single Japanese variety—with several rows of broad florets that are of the most brilliant blood-red colour imaginable, and particularly effective under artificial light. Section V., sub-section 2, a. F.C.C., N.C.S., October 27. Mr. L. Lawrence, Shoreham, near Sevenoaks.

The Daily Mail.—A very fine, large, high-centred Japanese variety of elegant form. The narrow florets curl and incurve loosely, and make up a bloom of considerable refinement, and one that will attract the attention of exhibitors. If name counts for anything, this variety should have a big circulation. Section II., sub-section 1, a. F.C.C., N.C.S., October 27. Messrs. W. Wells and Co., Merstham.

Calgary.—A showy, large-flowered, single variety, with regularly arranged, broad florets. The colour is crimson-bronze with a golden zone round the disc. Section V., sub-section 2, a. Commendation, October 27. Mr. Philip Ladds, Swanley Junction.

Miss Doris Hilder.—A dainty single variety that just comes within the large-flowered section. It has slender, stiff stems, that carry the flower erect. Colour, rich rosy-magenta. Section II., sub-section 2, a. Commendation, N.C.S., October 27. Mr. H. Hogbin, Sevenoaks.

Mrs. C. Farrar.—A beautiful solidly-built Japanese variety of considerable depth. It is of good shape, and the flattish florets droop gracefully. The whole of the centre of the flower is yellow, but the outer drooping florets are bright bronzy-buff. Section II., sub-section 1, a. F.C.C., N.C.S., October 13. Mr. G. Mileham, Emlyn Gardens, Leatherhead.

William Vert.—This is a very handsome, large Japanese variety, not so deep as some of the finest exhibition sorts, but of superb colour, with well-arranged spreading florets of a brilliant crimson shade, with golden reverse. With its fine stem and foliage, and sturdy appearance, this should become a favourite. Section II., sub-section 1, a. F.C.C., N.C.S., October 13. Messrs. W. Wells and Co., Merstham.

Connie Ingram. — A handsome single variety, with flowers 4½in. across on stiff, sturdy stems. The colour is rich crimson-red, with a narrow zone of yellow round the yellow disc. Section V., sub-section 2, a. F.C.C., N.C.S., October 13. Mr. Philip Ladds, Swanley Junction.

White Beauty.—One of the prettiest of pure white single chrysanthemums, and one that produces its blooms in natural, spreading, bouquet-like sprays of particularly elegant formation. For the garden or for market this should be a favourite, as it has good form as well as other good qualities. Section V., sub-section 1, b. F.C.C., N.C.S., October 13. Mr. P. Ladds, Swanley Junction.

T. Ward.—A beautiful free-flowering white variety, the flowers full, with narrow florets pleasingly and not too formally arranged. A lovely variety for cut flowers, as it has good stem and foliage, firm blooms, and pure whiteness. One plant shown carried twenty-six good flowers. Section II., 1, b. Market Commendation, 79 points out of 100. Mr. T. Ward, Bishop's Stortford.

Salvias. — When the autumn salvias have passed out of flower cut them back to the extent of half their growth, place them in a cool house, and give water sparingly. The beautiful blue S. Pitcheri, which flowers during the latter part of October and the beginning of November, is splendid for associating with chrysanthemums, and should be largely grown for this purpose. This species may be wintered in a cold frame with a little protection. Salvia Heri, which flowers during the dull winter months, is another useful subject for the conservatory. It must now have plenty of water at the roots, supplementing this occasionally with manure water.—E. Harriss.

YUCCAS.

These noble plants, with their distinct foliage and tall spires of ivory-white bells, are of inestimable value in the garden, since they combine hardiness with sub-tropical effect, and, when once planted, increase in dimensions and beauty from year to year.

Where sufficient space is available yuccas are never out of place, and are useful for a variety of sites. Perhaps they never create such a striking picture as when forming a large group on the grass, backed by evergreens. The numerous heads of varying size, composed of sword-shaped, spike-pointed leaves, some standing six feet above the ground level, and others resting their blades upon the grass, are picturesque in their outlines at all seasons of the year, and become particularly attractive when, in the autumn, a dozen or more tall flower spikes tower aloft above the strong, grey-green foliage. As a break in a long herbaceous border yuccas are valuable, a group of three or more plants coming well forward in the border giving a sense of informality by arresting the eye travelling down the long line of flowers with the relief of noble leafage.

As single plants on a lawn yuccas are decorative, and as the centre of a bed a plant forms an effective foil to the flat brilliancy of zonal pelargoniums and tuberous begonias. Yuccas look well in the rock garden, and make a telling contrast to the dwarf subjects with which such a site is for the most part filled; in fact, it may be said that well-developed specimens of these hardy plants are, whatever may be their surroundings, as worthy of admiration as any tender sub-tropical subject that can only be removed from a glass-house to the open garden for a few months in the summer. There are many species of yucca, but for all practical purposes the following four will suffice for garden decoration.

Yucca gloriosa.

This is a fine species, sometimes attaining a height of ten feet. Its tall and imposing flower spike is composed of many hundreds of pendant, ivory-white blossoms very closely set, which form a solid spire of flower. Its leaves are rigid, wide, and are terminated by a sharp spike.

Though handsome as a single plant, it is seen at its best when a dozen or more are planted in an informal group, each plant being distant about five feet from its nearest neighbour. When these have grown to a flowering size they form an exceedingly handsome feature in the landscape, and eventually grow into an impenetrable mass, with branching stems and cheveaux-de-frise of sword leaves, from which, in the flowering season, numerous tall bloom-spikes arise.

Y. pendula.

This is perhaps the most beautiful of all the yuccas, its curving leaves giving the plant a very graceful appearance. It is considered by some authorities merely a form of Y. gloriosa, but differs considerably from that species, for, in addition to its arching foliage being totally distinct from the stiff leaves of the latter, the individual flowers are far more sparingly set on the spikes. It is almost as robust a grower of Y. gloriosa, and may be similarly treated when selecting sites. It is sometimes known as Y. recurva.

Y. filamentosa.

This is a dwarfer species, seldom exceeding five feet in height. Its specific name is due to the thread-like filaments that hang from the edges of the sharply-pointed leaves, which together have earned for it the title of Adam's needle. It is a very free bloomer, and generally flowers annually, and, being of less vigorous growth, is suitable for quite narrow borders and for positions where the two already-mentioned species would be inadmissible on account of their size. This, and the next-named species, are yuccas for small gardens.

Y. flaccida.

This is, by some, thought to be a variety of the last-named, but it differs from it in that the older leaves are abruptly bent so that they appear almost broken. It is also somewhat dwarfer, rarely exceeding four feet in height. The flower panicles of the two latter species are more branching than those of Y. gloriosa and Y. pendula. All the four named here are natives of North America.

Wyndham Fitzherbert.

Kingswear.

LEAVES AND HUMUS.

Humus is decayed vegetation of any kind. It is Nature's restorative for hungry or impoverished soil. It enriches the earth, makes growth possible, and generally improves the condition of the ground. But how much of this valuable material is yearly wasted! Too often it is carted right away from the very garden which it would benefit. Sometimes it is burned; this is a moderately good practice if the resulting ashes are wanted, and wisely used.

A better plan is to dig a large hole (a hole is less unsightly than a raised heap) in an out-of-the-way corner of the garden, into which all refuse can be thrown. A prepared hole has also an advantage over a fire, as the smoke nuisance is reduced to nil, and this is no small blessing in some well-appointed gardens. Worn-out flower stems, faded flowers, weeds, roots, stalks, haulms of peas and beans, and cut grass will all make splendid material, when thoroughly decayed, for returning to the soil. Roots should be chopped through with the spade, and flower stalks, etc., cut into short lengths, to aid decomposition. Give the heap an occasional turn over during the year, and dust the top with soot or lime to prevent insects collecting and prevent the escape of any possible unpleasant odour.

When sufficiently rotted this decayed vegetation should be used like ordinary manure during digging or trenching. The latter operation will, in particular, swallow up the less decayed and more unwieldly material at the bottom of a good trench.

It will be wise not to throw into the hole any actually diseased material, such as "streaked" sweet-pea growths, club-rooted cabbage stalks, or tainted potato haulm. Such stuff should always be burned.

A word about fallen leaves. From these our leaf-mould is made. Preference is always given to oak, beech, or elm leaves where choice can be exercised, but any leaves collected and left to decay will make a really valuable compost for helping us in the production of our garden crops—whether out of doors or indoors. The best way to aid their final decay is to put them in a hole, as suggested, for the herbaceous and vegetable refuse. If some soot is mixed with them grubs will be killed and the leaf-mould enriched. The hole should be cleared out each autumn before any fresh leaves are put in, and the material stored in some convenient corner. C. Turner.

Ken View Gardens, Highgate.

JULY-FLOWERING LILIUMS.

(Concluded from page 780.)

L. pardalinum.

This is the tallest-growing of the Californian lilies, and one of the easiest to accommodate in our gardens, as it will grow and thrive in most soils. A considerable proportion of leaf-mould and coarse sand should be added to heavy loam and clayey soils previous to planting the bulbs. Light, sandy soil is improved for the culture of this lily by mixing in some old decayed manure and leaf-mould. Its tall, vigorous growth in peaty soils, when planted among rhododendrons, is familiar to many. Plenty of moisture at the roots is desirable in summer, but waterlogged ground should be avoided, as in this the bulbs will decay in winter. When planting, entirely surround the bulbs with coarse sand, and mulch liberally with half-decayed leaf-mould in June each year to keep the surface soil cool and moist. L. pardalinum has rhizomatous bulbs, which increase rapidly in good soils and favourable positions. Being a stem-rooting lily, plant the bulbs at least 6in. deep.

One could fill a column writing of the various positions in which this Californian lily may be effectively planted in the flower garden, pleasure grounds, shrubbery borders, and woodland. A group or two should find a place in the herbaceous and mixed borders, but for massing the association of trees and shrubs is desirable. A border with a western aspect, having a background of trees and tall shrubs, is one of the best positions for cultivating and effectively massing the pardalinum, or Panther Lily. Shrubs sheltering the lower part of the stems from 2ft. to 3ft. high are very desirable, nothing apparently doing more harm to this lily than the fierce rays of the sun scorching the stems and drying up the ground about the plants. In open brakes in the woodland the use of this lily is only limited by the extent of the domain and the number of bulbs available for planting. Replanting is not often necessary; but in time, perhaps, after growing in one position from five to seven years, the bulbs become very crowded, the flowering stems decrease in height, and the number of flowers on a stem are appreciably less. Then lifting and replanting is desirable, working in at the same time plenty of new soil.

L. pardalinum grows to a height of 6ft. to 8ft., sometimes more. It belongs to the Martagon group of lilies, having the familiar whorls of leaves on the stems, and the reflexed flowers, borne twelve to twenty or more on a stem. The bright orange-red blossoms are freely spotted with reddish-maroon. From the typical species numerous forms are in cultivation, with a considerable range of varying shades between yellow and scarlet, due, no doubt, to the ease with which L. pardalinum can be raised from seeds. The following are distinct:

Var. californicum, not so tall in growth as the type, might be described as a bi-color flower, the centre of the flower being orange, and the reflexed segments scarlet.

Var. Michanxi, later in flowering than the type, and more red in the blooms.

Var. angustifolium, a free-flowering variety of moderate height, with narrow leaves.

Var. Roezli, a dwarf form, with the leaves scattered more or less over the stem, and not in distinct whorls.

Burbank's Hybrid is a free-flowering lily raised by Mr. Luther Burbank, the parentage being L. pardalinum x L. Humboldti. The plants grow 4ft. to 6ft. high, and have orange and yellow or orange and crimson, prettily-spotted, recurving flowers.

L. concolor.

This is a charming little Chinese lily, with slender stems, 12in. to 18in. high, crowned with several upright, starry, scarlet flowers, with dark red spots. A group along the front of a border is pretty, but happier surroundings are a number of bulbs planted 4in. to 5in. deep in a pocket in the rock garden. The soil should be light and sandy, but the position not too dry, as moisture at the roots is very desirable during the growing season—early summer. The variety Coridion has deep yellow flowers, spotted dark red.

L. philadelphicum.

This is another lily, with upright, cup-shaped flowers, generally two to five on a

CATTLEYA GRANIRIS.

Petals and sepals light bronze, suffused with orange, lip purple-crimson. A.M., R.H.S., October 21. C. J. Phillips, Esq., The Glebe, Sevenoaks.

stem, and growing from 1ft. to 2ft. high. The flowers are orange-red, spotted black. A native of North America, L. philadelphicum thrives in a cool, well-drained, peaty soil, and should be planted 4in. deep among dwarf shrubs, above which the flowers may enjoy the sunshine.

L. Grayi.

A native of North Carolina, this lily might very well be described as a small-flowered red L. canadense. The average height is from 2½ft. to 3ft., but in this respect it varies considerably. The small funnel-shaped flowers are dark, rich red, freely spotted with purple. Plant the bulbs 3in. to 4in. deep among peat-loving shrubs, or in a bed consisting largely of flaky leaf-mould.

L. Washingtonianum.

A lovely lily from California that is seldom met with flowering in British gardens. This is to be regretted, for the slender stems, 3ft. or more in height, are very attractive, laden with white flowers tinged with lilac. In the variety purpureum the flowers change with age to a deep purple, the plant also being a better doer. Another variety, rubescens, has plum-coloured blooms. In all three forms the flowers are fragrant, and the petals very much reflexed. Plant the bulbs at least 6in. deep on a partially-shaded border.

L. canadense.

As the name suggests, this is a North American lily. Growing 3ft. to 4ft. or more in height, the tall, slender stems bearing the bell-shaped flowers are very graceful. The colour of the flowers varies considerably, from yellow to orange-red. The typical plant is considered to be the one with orange-yellow flowers, spotted with reddish-black. The golden-yellow form is known as flavum, and an orange-red variety as rubrum. The best position for L. canadense is in a bed of peat-loving shrubs. The bulbs are rhizomatous, and may be planted 4in. to 6in. deep.

L. chalcedonicum.

This is the old scarlet Turk's Cap of the cottage garden. It is, unfortunately, not so often met with in a flourishing condition as formerly. L. chalcedonicum thrives in the usual soil found in a good herbaceous border, and when flowering freely should not be disturbed. Plant the bulbs 3in. to 4in. deep. Growing 2ft. to 3ft. in height, each stem carries from four to eight waxy-scarlet flowers. Several groups of this lily, consisting of eight or ten bulbs, may be made a very effective feature of the herbaceous or mixed border. A. Osborn.

Cleansing Fruit Houses.—The work of pruning and cleansing in fruit houses must now be carried out in all except the late houses. A clean start is absolutely necessary to success, and the work cannot be too carefully performed. Red spider and mealy bug are the worst pests. I do not like extraordinary mixtures of clay, tar, etc., but prefer a soapy insecticide or Gishurst compound. Repeated washings are necessary for these pests, and the cleansing of the vines is not the most difficult part, as mealy bug gets into the wall crevices, trellises, and other places where they are most difficult to dislodge. When all cleansing has been properly performed, a persevering man, with a small brush and some methylated spirits, giving daily attention in the spring when the vines break, and afterwards, will keep all clean.—F. Jordan, Warter Priory Gardens.

VIOLAS, OR TUFTED PANSIES.

The article by Mr. Smith on "Tufted Pansies" in the "G.M." of October 11 puts the case of the viola in a most interesting manner. Without in any way going over the same ground, I wish to supplement his notes with a few of my own. Violas are deservedly popular, and the list given of some of the florists' varieties includes many general favourites.

Leaving these, I want to call attention to some lesser-known violas, which are invaluable for garden decoration. These will be found to stand the drought of summer and the keen frosts of winter much better than the race of florists' varieties. Of their parentage I need only say that in the majority the influence of the hardy Grecian Viola gracilis is fully apparent.

The underground creeping stems, the dwarf close habit, the wonderful profusion of blossom, the greenness of the tufts throughout winter, and the ability to withstand both heat and cold, gives the new race an opportunity to gain a great popularity in English gardens. Not only are they splendid for rock gardening, but also for spring bedding and border planting, and wherever violas or pansies can be used these novelties are certain of success.

Grandeur, a rich dark blue, with just a few pencillings of black, is very noteworthy. The near varieties to this are Undine, a clear soft blue; Gold Eye, a medium blue, with a gold eye; and Superba, a glorious purplish-violet, while the former, named after the writer of these notes, is remarkable for its violet hue and its conspicuous white eye. These are all ideal bedding varieties.

Snowdrift should prove valuable for massing, or as a carpet to bulbous plants. It is white, save for the dark-blue centre blotches, and the most continuous-flowering viola I know. Inspiration, the stock of which is in the hands of a well-known hardy plantsman, provides one of those haunting shades of blue which defy description. Poised upon long, stiff stems, and possessing a golden eye, this glorious little viola should prove a great attraction to the flower lover. The yellows, Golden Wave, Golden Fleece, Aurea, and Marjorie, are each finding a big circle of admirers. The first-named is probably the most fragrant of all hybrid violas, and makes a glowing mass. Golden Fleece is smaller, almost a typical yellow Gracilis, identical in growth and form. Marjorie is a primrose-yellow, gracilis, and one of the daintiest flowers imaginable; while Aurea is a neat dwarf form, with soft refined blossoms of great beauty.

Red Wing, a brilliant ruby-hued miniature viola, gives a fine touch of colouring, and others on the same lines, though somewhat larger, are St. Vincent, Ruby Drift, and the small-flowered Rubella.

Gondolier furnishes a distinct type of dwarf neat habit. This variety carries blossoms of a sulphur shade, deepening to gold at the centre. In Iris and Lady Grace we have two little gems in silvery-mauve and violet. These are delightful, and hold their blososms splendidly, while Elsa, a near companion form, carries smaller blossoms of ruby-purple and palest mauve over a groundwork of dwarf foliage.

Other varieties might readily be noted, but I bring these to the notice of garden lovers in order that they may be more widely utilised. As many of these are readily obtainable from hardy plant specialists, and the few others will probably soon follow them into general cultivation, there is no good reason why some should not be given a trial by viola lovers as a preliminary to larger plantings later.

P. S. Hayward.

AUTUMN-FRUITING RASPBERRIES.

(Concluded from page 827.)

Varieties.

We grow, at the present time, three varieties only, and these serve our purpose well, viz.:—

The Hailsham. — This is a strong grower (five feet) with us, and a most abundant cropper, too. The individual fruits are large, and of a good colour. It makes a fine dish for the dessert. The fruits are round and solid, otherwise firm. Its constitution is somewhat remarkable. I have taken up young suckers in the spring from between the rows with some roots attached, and replanted them; these have grown away and produced a few fruits the same season. It was raised at Hailsham, in Sussex, by a Mr. Dann, and was put into commerce by Mr. William Knight, of the same town, a few years back.

The Alexandra.—This is proving itself to be an excellent variety, and not quite so tall in growth as the preceding. It has also the reputation of being of first-class flavour. The fruits are large, deep-red in colour, and of conical form. It was raised and first distributed by Mr. William Allen, of Gunton Park Gardens.

Merveille Rouge (syn., Belle de Fontenay).—This variety is the dwarfest of the trio, and, in my opinion, it is the best for a limited space or a small garden. It fruits abundantly, though some of the fruits may be small. The colour is dark purple, and somewhat round in shape. It also crops very late in the autumn with us at Gunnersbury.

I have tried the autumnal yellow varieties, but have not found them to be satisfactory. Mr. S. T. Wright, of the R.H.S. Gardens at Wisley, informs me that the best six in the trials there have proved to be Surpasse, Merveille Rouge, Perpetual de Serriere, Everbearing, Feldbrunner, Surprise d'Automne, Surprise Fastolf, and Merveille Rouge.

Further Notes.

In a well-known and well-kept garden, not many miles from Paris, I saw, on one occasion, in October, a very fine crop of a strong-growing variety. This crop was covered over by a temporary shelter, with glass as a lean-to, with the back boarded up. Such a crop would, without doubt, last well into November.

We have now grown these autumn-fruiting raspberries at Gunnersbury for seventeen years, and all that time upon the same plot of ground. In conclusion, I recommend their culture with every confidence, especially in the southern counties of England.

Jas. Hudson, V.M.H.

Gunnersbury House Gardens.

Garden Pests.—An invaluable handbook is "Garden Foes," which gives a descriptive account of the various Pests and Diseases affecting indoor and outdoor crops, and the most up-to-date remedies for their prevention and eradication. The volume is well illustrated, and can be obtained for 2s. 10d., post free, from Gardeners' Magazine Office.

LATE DESSERT PEARS.

There is much diversity of opinion as to the best soil for pears. Some tell us that a light, warm soil, resting on sand or gravel, is essential to fine fruit; others say that a deep, rich loam is preferable; while others point to those fine old trees that are to be found in some of the orchards in the western counties that have attained such dimensions while growing in blue clay. There is not a doubt that both soil and situation have much to do with the quality of fruit and the growth of the trees. Those fine old pear trees in the West are only once removed from the wild type; they are natives, and, therefore, quite distinct from those tender kinds brought from warmer climes. Pears grafted on the quince come into bearing sooner, and ripen their fruit earlier, than those grafted on the pear stock. I have had trees of the same variety growing side by side grafted on the two kinds of stocks, and one would ripen its fruit fully three weeks earlier than the other. Trees growing on a warm, sandy soil produce finer and better-flavoured fruit than those growing on a cold clay.

Gathering.

All late pears should be allowed to hang on the trees as long as possible, as they will then ripen at a much later period, and be of far finer flavour than when gathered before they part freely from the stem. As an instance of this, I have sold such varieties as Beurre Diel, Hacon's Incomparable, Van Mons, Leon Le Clerc, and Doyenne du Comice at from 6s. to 8s. per dozen at Christmas time, whereas had the fruit not been allowed to hang until late it would have ripened before that period, and in all probability not have realised so much money. In some seasons pears ripen very peculiarly, but this is due to the supplies of water they receive during July and August. If the weather during those two months is showery, or wet enough to keep the soil moist, the fruits do not ripen so quickly, and will hang long on the trees. This being so, it is advisable to mulch the trees, and afterwards give them liberal supplies of water to keep the roots moist. If this be done thoroughly those that are classed to ripen in November may be kept good for a month longer, and the later kinds in like proportion.

There is often not sufficient attention paid to gathering the fruit. Not only are some kinds ready to gather sooner than others, but the fruits on the same tree are not all fit to gather at once; this being so, it is advisable to examine the trees two or three times, taking only those that part freely from the shoots. Then again, the rough way some men handle the fruit is sufficient to account for it not keeping sound for any length of time.

I was in an orchard the other day where some men were gathering pears. There were several tons of one variety nearly ripe. These were pulled from the trees and thrown into rough wicker baskets as though they were so many stones; they were then turned out of these baskets into hampers, so that by the time they reached the market half of them would be so bruised as to be almost worthless. One cannot be surprised at their realising not more than £4 per ton, whereas had they been carefully gathered and graded they would, in all probability, have sold for not less than double that figure, as they would have made a fine sample. One cannot be too careful in handling fruit of any kind, more especially that which has to be stored for some time. The fruits should always be gathered when dry, or, if not perfectly so, should be allowed to remain in an airy shed for a time until all moisture has evaporated before being taken to the fruit room.

Fruit Room.

A word or two about the fruit room may not be out of place. I have seen fruit stored in all sorts of places, from damp cellars to heated structures elaborately fitted up, but have never seen it keep so well as in a room of uniform temperature. Such a place need not be a costly affair, but it is essential that it be free from damp, as a superabundance of moisture about the fruit is sure to cause rotting; at the same time a heated structure should be avoided. A thatched building is preferable to one either tiled or slated, and if the thatch be of sufficient thickness it will exclude the frost. If the sides are of wood, that, too, should be covered with thatch to maintain an even temperature. The room should be provided with an inner and outer door, the outer one being closed before the other is opened, in order to prevent a too sudden change of temperature. I have often seen the fruits in fruit rooms as wet as though they had been taken out of water, this being caused by a too sudden change in the temperature. Sometimes, after a spell of cold weather, we have a sudden change, and, forgetful of the harm they are doing, people will put open the ventilators of the fruit room, forgetting that the temperature there is much lower than the outside air. This causes condensation, which it is most difficult to expel except by fire heat, and this is not advisable to use as it has a tendency to extract moisture from the fruits and they mature sooner than required.

Varieties.

In order to assist late pears to attain their full flavour they ought to be taken out of the fruit room to a warmer place for a few days to ripen. By adopting this method the supplies will be considerably prolonged, as it is not necessary to remove more than are needed for a short supply. There are many good-flavoured pears in use during January and onward to March, but as they are not exhibition varieties they are not well known, because they rarely come prominently before the public. These varieties should be known to all gardeners who are called upon to keep up a supply of dessert pears. In Glou Morceau we have a large variety, which, when well grown, has a rich, delicious flavour. When fully ripe the skin is a greenish-yellow on the shaded side, while that exposed to the sun is sometimes covered with russety spots. This variety is particularly valuable as it remains in good condition for some time after it is fully ripe. Le Lecteur is a large variety of recent introduction, with pale yellow or greenish skin. When well grown it is a handsome fruit, and, like the above-named, has soft melting flesh of excellent flavour, especially when grown against a south wall. Huyshe's Victoria, though not a large pear, will grow to rather more than the medium size. The skin, when ripe, is yellowish, though often freckled and veined with russet to such an extent as to almost hide the yellow. This is a first-rate pear of excellent flavour when grown against an east wall and allowed to hang as long as possible. Beurre de Jonghe, a rather long, russety-looking pear, is of first-rate quality when grown on a warm, sandy soil, but should be allowed to hang as long as possible to attain its full flavour, otherwise it is apt to be gritty. Beurre Bachelier is a large pear, and its skin, when ripe, is covered with russety spots. Flesh, soft and melting.

Beurre Sterckmans is pale green on the shaded side, while on the exposed side it is often dull red. It is a very handsome pear, and of first-rate quality. Forelle is one of the most handsome pears grown, and, though not an exhibition variety, is without doubt one of the best-flavoured kinds in cultivation. The skin is smooth, and, on the shaded side, a fine lemon colour, while on the side fully exposed to the sun (when grown on a south wall) it is crimson, often strewn with very dark crimson spots, suggesting a fine-coloured trout, hence its name of trout pear. Unlike many others, this will keep in good condition for some time after it is fully ripe. To obtain good-sized fruits thinning should be done early. Winter Nelis is a grand winter pear of medium size, with a russety skin. It is one that requires very careful handling as the flesh is soft long before the fruits are fully ripe. Easter Beurre when well grown, is highly-flavoured but the skin is so hard that fruits are apt to crack unless the trees are in a flourishing condition. A warm, light soil suits it best.

Jean de Witte is rather below the medium size, having a bright yellow skin on the shaded side, while the exposed side is often covered with russet. Flesh is soft and finely grained; after the stamp of Le Lecteur. The tree is an abundant cropper, even in unfavourable seasons, and must, therefore, be thinned early if we would have the fruit of fair size. Josephine de Malines is a pear of great excellence; skin yellowish on the shaded side, and often tinged with red on the sunny side. Like many other small varieties, this is an abundant cropper, and, therefore, needs to be thinned early, so that the fruits may attain a fair size. Bergamotte d'Esperen is not by any means a pear that attracts, but when well grown, and the fruit properly ripened, it is excellent. The tree is usually a prolific bearer, and often requires severe thinning. Ne Plus Meuris is another small variety that requires to be well known to be thoroughly appreciated. It has a rough russety skin, but the flesh is soft and melting. Olivier de Serres, though not large, the fruit is usually rather above medium size, and has a russety-looking skin. It is highly flavoured, and sweet. Nouvelle Fulvie is large; skin yellow, thickly spotted with russet. This is an excellent late pear, and is usually most prolific. Passe Crassane is a medium-sized well-flavoured variety that is much improved by being grown against a south-west wall in a rich light soil. Beurre Rance is without doubt a fine late pear, and though in some places it will do well in the open, the quality is usually much improved if trees are grown against a wall.

With so long a list of varieties to choose from there should be no difficulty in keeping up a supply of late pears, provided the soil and situation are favourable, and a suitable structure is provided for keeping them in.

H. C. Prinsep.

PEGGING DOWN ROSES.

The pegging-down system of rose culture has much to recommend it for gardens in which it is desired to grow the strong-growing varieties in beds, whether in association with those of dwarf growth or occupying isolated positions in the garden. By no other method can such strong growers as Frau Karl Druschki, Gloire de Dijon, Hugh Dickson, and William Allen Richardson be successfully utilised in the furnishing of beds, and it is surprising the pegging-down system should not have been taken more fully advantage of. The system is the best for both small and large gardens when it is desired to cultivate varieties of robust habit in beds, but it possesses exceptional value for gardens when the area is such as to admit of the arrangement of roses in bold masses.

The pegging-down system differs chiefly from the orthodox method of procedure in the management of dwarf-growing varieties by the utilisation of practically all the strong growths of the previous season for flower-production. At the winter pruning of the varieties of dwarf or moderate growth the shoots of the previous year are cut back to within from three to nine inches of the base, according to their habit. Were the long, stout rods of the strong growers to be cut back in a similar manner they would produce numerous other strong growths, and but few flowers. With a view to obviate an excess of growth, and ensure a plentiful production of flowers, a quite different course of procedure is followed at the winter or, to be more exact, the spring pruning. First of all the old wood that produced flowers in the year previous is removed by cutting it away within a few inches of the base. The next step is to cut the weakly shoots back close to their base, and to shorten the strong, rod-like growths by taking six, nine, or twelve inches off the top. The length taken off is determined by the degree of ripeness of the wood, the object being to remove as much of the rods as is soft, or insufficiently mature, and, therefore, likely to die back early in the season. The pruning having been completed, the rods are brought down to a more or less horizontal position and made secure with the aid of stout pegs, standing from eight to twelve inches above the surface, or pieces of wood of a similar length, and strands of stout raffia or tar-twine.

Thus trained the greater proportion of the buds, if not all, start into growth, and flowers are borne throughout the whole length of the shoots, and produce a surprisingly beautiful effect. If the varieties are perpetual-flowering, and these only should be planted, there will be a continuous succession of flowers throughout the season. New growths will rise during the summer, and these should be allowed to grow unchecked unless they are overcrowded. They may be thinned by the removal of a few of the weakest. At the winter pruning the old wood will be cut away, and the young rods trained horizontally, in accordance with the advice given above.

A few of the best roses for this system of culture are Climbing Lady Ashtown, Frau Karl Druschki, Gloire de Dijon, Gruss an Teplitz, Hugh Dickson, J. B. Clark, Lady Waterlow, Madame Jules Gravereaux, and William Allen Richardson. An illustration is given of the last-named variety, and this is of interest as evidence of the beautiful effects that may be obtained in the garden by means of the pegging-down system. G.

A SUCCESSFUL EXAMPLE OF THE PEGGING DOWN SYSTEM OF ROSE CULTURE AT KEW.
The variety is William Allen Richardson, which produces its rich orange-yellow flowers freely and continuously throughout the summer.

APHIDES ON ROSES.

I have noticed more than ever during the past season how great are the depredations committed by green-fly on roses, especially those of the climbing section. So badly were roses affected that not only was the flower crop ruined but the plants did not make their usual vigorous growth, which is all against satisfactory results next year.

Climbing roses need quite different treatment to the ordinary teas or hybrid teas, because the amount of growth made one season governs the quantity of blossom the next year. In the case of dwarf varieties, the bulk of the shoots are pruned off, and the flower crop is provided by current season's growth.

In a recent leading article in the "G.M." stress was laid upon the way climbing roses were provided with water at their roots, and it was suggested that where watering was efficiently done the plants were not badly attacked by aphides. With this I fully agree.

I cannot arrive at any other conclusion

than this, namely, that the failure on the part of the climbing roses to provide a full crop of flowers during the past season was due mainly to neglect in checking the spread of the aphides early in the year, and so the pest crippled the growth of the plants for the whole season. This year I saw many climbing roses infested with aphides that were sapping the life of the plant, and not a single remedy to check the progress of the fly had been attempted, on the weak plea that there was a bad attack and there was no use troubling further. My experience is that if the climbing roses are thoroughly syringed with an efficient insecticide directly the first aphides are seen, and again as a preventive in ten days' time, they are kept quite clean for a considerable period, growth makes progress, and the flower buds develop fully.

There are many insecticides now available, but the one that I have found most efficient is known as Katakilla, at the rate of two ounces of the powder to three gallons of soft cold water. I dissolve the powder in a little water, and then add the full quantity, keeping the whole well stirred, and applying it with an ordinary fine-nozzled syringe, thoroughly wetting the stems and foliage. This spraying is done in the evening, as then the liquid dries very slowly, and is, as a consequence, more deadly in its effects on the pests.

I give my plants a thorough washing with clean water the following morning, to cleanse the foliage of dead insects. I may add that this preparation leaves no sediment on the leaves. E. Molyneux,

Bishops Waltham.

FRAGRANCE IN THE GARDEN.

Few will quarrel with the assertion that fragrance in the garden is not so well arranged for as in the old days, when various herbs, most of them with fragrant leafage, were considered as essential—as much for their sweetness as their economic value. In common fairness, however, it must be allowed that this matter of fragrance in the garden is again receiving attention: in one direction it finds expression in an outcry against the multiplication of scentless roses, sweet peas, and carnations, and in another direction we find sites in well-ordered gardens devoted to hardy plants that yield sweet perfume through leaves or flowers, but especially through the former.

With his usual originality, Sir Frank Crisp, Bart., has a sun-dial garden, which is also "a garden of sweet scents and savours," at Friar Park, Henley. Here, in quaint box-edged beds and beside paved pathways, old-fashioned herbs are associated with the best of modern fragrant plants. Lavenders, thymes, sages, mints, rue, borage, bergamot, sweet cicely, marjoram, and many another plant that found favour with the housewife and the housekeeper a few generations ago, find a suitable home, and there are artemisias, pinks and carnations, mimuluses and santolinas, woodruff and violets, phlòxes and gum cistus, sweet briars and honeysuckles, and many another herb or shrub to add their charm of form and colour to that of sweetness. The knowledge that some plants and flowers diffuse their fragrance more readily in the evening than at any other time of the day is also made good use of, and should be borne in mind by every planter who walks in the garden at the cool of the evening. Alas! too many gardens now-a-days lack "sweet savour," therefore, at this season of the year, when alterations and new plantings are being carried out, the illustration of the fragrant garden at Friar Park may be left to point its own moral, "with all thy getting, get sweetness." C. H. C.

THE GARDEN OF FRAGRANCE AT FRIAR PARK, HENLEY.

The residence of Sir Frank Crisp, Bart.

PINUS ARMANDI.

In general appearance this Chinese species bears a striking resemblance to the Blue Pine of the Himalaya, Pinus excelsa, and the Hickory Pine of Mexico, P. Ayacahuite. But a close inspection will show that it is quite distinct from either species, both by reason of the curious kink at the base of each leaf, and by its shorter, wider, and blunter cones. Belonging to the five-leaved section of the genus, it promises to become quite as useful for decorative purposes as either of the better-known species, although the largest trees in this country are barely more than eighteen feet high. These are growing in the Arboretum at Kew, and were raised from seeds collected by Professor A. Henry, at Mengtze, in Yunnan, about 1877. They coned for the first time twelve years later, but so far no fertile seeds have been produced.

In its native habitat it attains a height of 60ft., and is described as having smooth, greenish bark. The branchlets are smooth and glabrous, or sparingly clothed when young with small hairs. The leaves are slender, glaucous, and four to six inches long, while the cones also are four to six inches long. W. D.

GOOSEBERRIES.

The gooseberry is one of the hardiest of our cultivated fruits; in fact, it succeeds better, and can be grown in many instances to a higher degree of perfection, in the midlands and the north, than in the warmer southern parts of these isles. The simplicity of culture, together with a prolific habit and usefulness, accounts for its popularity. As dessert fruits, the best-flavoured varieties are greatly appreciated, even by those who can command a supply of the more highly-classed fruits. Gooseberries are valued when preserved, either in a ripe or green state. In their latter condition they are especially useful for tarts and for other cooking purposes, and in this way afford a supply of fresh fruit at a season when there is a scarcity of other kinds.

Situations of Plantations.

It is advisable, owing to the varied effects climate has upon the gooseberry, to be careful in the selection of favourable situations for plantations. In southern districts, especially upon light soils, and in hot, dry seasons, plants placed in very sunny positions suffer considerably, and their crops when ripe are, as regards flavour, of inferior quality. In such cases, therefore, a cool and, if possible, a semi-shaded situation should be found. In northern, and consequently cooler localities, open quarters fully exposed to the sun are perfectly satisfactory.

I well recollect the heavy crops of fine fruit produced at Crimonmogate, Aberdeenshire, upon bushes planted in the most sunny positions, by the sides of the kitchen garden walks, and the excellence of the flavour of such varieties as Red Aston (Warrington), Glenton Green, and Ironmonger. The fact that "the berry" succeeds so well in this, probably one of the coldest parts of Scotland, is a sufficient proof, if proof was wanted, of its hardiness. Cordons of all descriptions, or fan-trained plants, succeed admirably when planted against trellises or walls, and when suitable varieties occupy positions against walls having a northern aspect the fruit can be preserved in good condition until quite late in the season.

Planting.

Light or thin soils are unsuitable, as the gooseberry is shallow-rooting, and readily suffers in dry weather if planted in them. A fairly deep, sound loam is the best soil to plant in, and this should be prepared by first being bastard trenched, and then by having a good dressing of farmyard manure dug into the top spit. Planting is best done at the beginning of November, and in forming bush plantations the rows should run north and south, and the bushes be placed at least 5ft. asunder each way. Cordons when planted in the open should be provided with trellises or fences running north and south, parallel to each other, and six feet apart. In all cases the work should be completed by mulching the surface with half-decayed stable manure.

Pruning and Training.

In order to secure well-formed, prolific bushes, an intelligent and painstaking system of pruning and training must be followed, and though this is a simple matter, it is quite a common thing to find, in this respect, badly-managed plantations. When commencing with newly-planted young bushes, their growths should be cut back to within about eight inches of their base early in February. This will promote the production of an ample supply of young shoots to form the foundations of perfect bushes. In June the surplus growths over and above those selected to remain should be cut away, and careful attention should be given to avoid the common mistake of crowding the bushes with wood; the shoots left should point outwards, and not cross each other. The after treatment will consist in stopping the lateral shoots back in June to about three inches, and in winter cutting them back to two buds, and shortening leading growths to the desired length. Some varieties produce fruit more freely upon young wood than upon spurs, and in pruning this should be borne in mind, while in all cases young wood should be introduced to take the place of declining branches.

Cordons are usually trained vertically, and may consist of one or more stems as desired. Those with five stems, placed at ten inches apart, are of convenient proportions, and even when planted together, as cordons invariably are, their roots are afforded sufficient space to ramify without detrimentally encroaching upon each other. This system of training is very simple, and the pruning of fully-developed plants merely consists in shortening the lateral growths in summer, and spurring them back in winter. Upright-growing varieties are the most suitable for this mode of culture.

Varieties.

Only those who have seen gooseberries in the plantations of specialists, or have seen such collections of varieties as those that have from time to time been staged at Vincent Square, can realise the large number of varieties there are under cultivation, and few of us have had cultural experience of more than a very small percentage of them.

For ordinary purposes a comparatively small selection suffices, and the following are twelve good useful gooseberries: Red Warrington, Glenton Green, Whinham's Industry, Whitesmith, Keepsake, Crown Bob, Langley Beauty, Langley Gage, Ironmonger, Red Champagne, Green Gascoigne, and Leveller.

VERONICA SPECIOSA.

Visitors to the Royal Horticultural Hall during the autumn months have usually a good opportunity of observing the value of the different varieties of Veronica speciosa available for greenhouse decoration at this season. Messrs. H. B. May and Sons have for many years made a speciality of the culture of these beautiful flowering shrubs, and have brought together an extensive collection, whose flowers range from white to deep crimson and purple. The plants exhibited are neat little bushes, in the regulation 48-size cut, or one five inches in diameter. A few standards are, however, grown, as there is at the present time a considerable demand for standards of all kinds of different subjects.

If the dwarf plants are shifted on into larger pots good-sized bushes may be had if desired. Apart from the beauty of their blossoms, a valuable feature connected with these veronicas is that they are of easy propagation and culture, as cuttings of the young, growing shoots strike root without any difficulty if kept in a close frame, and the young plants so obtained will grow away freely afterwards. They should be stopped once or twice in order to ensure bushy specimens. In the milder parts of the country, especially in proximity to the sea, these veronicas are quite hardy, and they then form a beautiful race of evergreen flowering shrubs.

W. T.

SHRUBS AND TREES FOR SEASIDE GARDENS.

A gardener who has followed his profession in inland districts would be likely to make mistakes if he moved to a seaside garden and commenced the work of planting trees and shrubs there. Even persons very experienced in the matter of seaside gardens often err. Subjects that thrive in inland districts would, in many instances, soon become sorry-looking things in a garden exposed to storms from sea, accompanied, as they often are, by salt spray.

I have seen the young shoots of all hedges gated sorts in the inner lines; berberis in variety, the tree box, veronicas, and sweet bay and tamarisk.

The following trees are suitable for forming a high shelter: The silver fir, Thujopsis dolobrata; evergreen oak, sycamore, the Lombardy and white poplars, elm, elder, laburnum, Cupressus macrocarpa lutea, and the Mountain Ash. Where a high, thick shelter is required, a judicious selection of trees and shrubs must be made. It is a mistake to plant too closely, as strength of individual tree or shrub cannot thus be and trees, that were directly exposed, for a distance of many miles along the coast, and for nearly a mile inland, quite browned and shrivelled up, like the leaves of tea ready for use, after an exceptionally severe storm from the sea, and such storms frequently occur. Some of the pines were not much affected.

Trees and shrubs for shelter must be the first consideration on the part of the gardener. Nearly all used will, in time, become seared on the seaward side; but this cannot be helped, and it must be endured for the sake of having other subjects inside preserved in good condition. For a low shelter the following shrubs may be planted, namely: Evergreen privet; Aucuba japonica—this shrub does well in a heavy soil and in draughty places; escallonias; the Common Holly on the extreme boundary, and the broad-leaved and varie- obtained. If each one has ample room to develop in, a substantial wind-break will result.

The soil, even if it be of a very sandy nature, should be rather deeply trenched. Furthermore, plenty of rotted manure should be put in at the time of planting. It may be thought by some persons that a rich rooting medium would cause a too luxuriant growth, and that the tender shoots so made would suffer from the strong gales. A very rich rooting medium is not desirable certainly, but a really good one is needed. When the trees and shrubs are planted in poor soil, few roots are made, and then they are soon blown over, and become permanently one-sided. Good soil is soon filled with healthy roots, and these roots support the tree very firmly, the lower branches grow strongly, and all this conduces to the effectiveness of the shelter necessary for the protection of the choice subjects in the garden.

Some very choice shrubs and flowering trees may be grown near the seaside, where it is possible to protect them to a great extent from strong winds. I only need mention the lovely Choisya ternata, with its fragrant white flowers.

Many years ago I had some valuable experience in a garden overlooking Morecambe Bay. A very long hedge of laurestinus, growing above a low stone wall, was unsatisfactory. Immediately in front of it we fixed a band of half-inch wire-netting. In a very short time this simple wind-break proved most effective, the plants made rapid growth, and the blanks in the hedge soon filled up.

GEO. GARNER.

CLAY'S FERTILIZER THE STANDARD PLANT FOOD

"THERE IS NOTHING LIKE CLAY'S TO BUCK THINGS UP."

The Fruit-Grower.

SOLD EVERYWHERE in **6d.** and **1/-** TINS; and in BRANDED and SEALED BAGS:—7 lbs., **2/6**; 14 lbs., **4/6**; 28 lbs., **7/6**; 56 lbs., **12/6**; 112 lbs., **20/-**.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

SEASONABLE NOTES.—In the neighbourhood of London and other large towns, where fogs are so detrimental to plant life in general, I have found that the only means of minimising the disastrous effects of such atmospheric conditions is to keep the plants and the atmosphere as dry as possible, and allow the temperature to fall a few degrees below the usual figure. All ventilators and doors should be kept closed during fog, and everything, such as covering any opening at the base of the door with a wet mat, and packing loose joints in woodwork, etc., should be done to keep the fog out and minimise its effects. It will generally be found that the flowers show little injury until the fogs have lifted and brighter conditions prevail. It is also curious that cut flowers in use for house decorations do not suffer to the same extent as those on the plants, especially so where the flowers have been cut a few days before the fogs began. No orchids withstand the injurious effects of fog more succesfully than cypripediums.

THE ROOF GLASS.—In all foggy and smoky areas there is a considerable deposit on the glass roof during winter, and it is desirable that this obstruction of light should be regularly washed away.

TEMPERATURE AND WATERING. — With the rapid shortening of the days the temperature in practically all the divisions may be lowered to the winter reading. With favourable conditions and a clear outside atmosphere, there will be considerable fluctuation during the middle of the day, but this may be counteracted by a discreet use of the lower ventilators. A slight warmth in the hot-water pipes is desirable, so that the air admitted may become warmed before reaching the plants. The water in the rain-water tanks, after heavy rains or sleet showers, will be found considerably colder than the temperature of the house. It is desirable, therefore, before watering to warm the water a degree or two higher than the reading in the house. This may be considered a fad, but I am convinced that many of the more tender orchids suffer very considerably from the use of cold water.—H. J. CHAPMAN, Oakwood Gardens.

STOVE PLANTS.

IXORAS.—Plants that have flowered may, from now until required for starting next season, be kept in a light position in the intermediate house, first removing all flower spikes and any weakly or superfluous growths, so that the remainder may be thoroughly ripened. Young plants from cuttings inserted last spring will be carrying from three to five good flower trusses each; keep them on the shelf or in a fairly dry position near the glass, and, if necessary, carefully sponge the foliage.

ACOKANTHERA SPECTABILIS. — This stove flowering plant has much the appearance of an ixora. Its flowers, appearing in spring and early summer, are white, beautifully scented, produced in profusion on well-grown plants. It may be propagated by means of cuttings of the young wood obtained after flowering, or by sowing seeds in early spring. A most suitable compost consists of two parts loam, one each leaf-mould and peat, and a fair addition of sand. Having nearly completed their growths, the plants may be kept at the cool end of the stove where they will not require much water during the winter months. Young plants should be kept growing in a warm position.

BOUGAINVILLEAS.—By this time bougainvilleas should be in a fairly well ripened condition, and may be rested in a warm greenhouse until starting time in spring. The same remarks will apply to Clerodendron Thomsonæ.

CALLICARPA PURPUREA.—This will now be set with berries which are fast assuming their purple shade. It is very useful as a decorative subject, grown either in pots or baskets. Attention with regard to staking and tying will be necessary to ensure a shapely appearance. Every care should be taken to keep the plants in good condition as long as possible, water being supplied with great care.

STORING SOIL, ETC.—With the approach of winter potting operations have practically ceased for this year. To ensure a supply of compost in good condition early in the New Year it will be well to place in the dry a quantity of loam which has been cut and stacked out of doors during the past summer. Clean oak and beech leaves gathered last year will now be in the form of leaf-mould, and should be brought under cover. —H. PRIME, Hatfield Gardens.

FRUITS UNDER GLASS.

PINEAPPLES.—The weather of late has kept mild and open, and late-fruiting plants have been materially helped by the sunshine, the atmosphere being kept moist by the use of the syringe and damping down. The earliest stock plants intended to make a little growth before they throw up may be kept more freely supplied with atmospheric moisture by damping the walls, etc. Rest must, however, be secured by allowing the temperature to fall a little, according to the weather. A general reduction all round in heat and moisture will now be necessary. Provided the tan, or leaves, are mounded up round the pots to keep the roots equally moist, these plants will require little or no water, but excessive drought must be guarded against; 60 degrees at night and 70 degrees by day, with 70 to 75 degrees as a fair bottom heat, will keep everything safe at this season.

LATE MUSCAT GRAPES.—These will now be fully ripe and well coloured, and care must be taken that they are not overdone with fire-heat, neither must they be allowed to suffer from damp. A gentle warmth in the pipes, with a moderate circulation of air on fine days, will generally keep the berries fresh and plump. A temperature of about 50 degrees at night will be suitable; but much depends upon the structures and the surroundings.

LATER GRAPES.—Keep the pipes in the late houses sufficiently warm to maintain a steady circulation of fresh air, and at all times avoid sudden falls of temperature. If watering is necessary, choose a fine bright morning, with fair warmth in the pipes, and a good circulation of free air. Thin-skinned grapes will now keep quite as well, and possibly better, in the grape room than upon the vines, and by clearing the houses the vines are given a rest before being pruned. If the grape room has not been cleansed, no time should be lost in getting it put in order by lime-washing, and otherwise making it sweet and clean.

STARTING VINES.—Such varieties as Lady Downes keep so well that hard forcing is now rarely needed, and the best method of procuring very early supplies of grapes without weakening the permanent vines is by the use of pot vines, provided these are ripe and well rooted. Successful forcing depends more upon the preparation of the vines than upon any detailed operations afterwards. Pot vines that are well rooted, and that have had a good rest, may be started this month with every chance of success. Having been shortened back some weeks ago to their proper length, there should be no danger of bleeding; but to make sure, a touch of styptic should be given. Where they can be plunged in a bed of leaves with a little short horse litter added, with a bottom-heat of 70 to 75 degrees, so much the better. Tepid water also plays an important part at this season. If the buds are prominent and likely to respond to mild treatment the temperature may range from 48 to 53 degrees at first, with the usual rise during day. Permanent vines with inside borders answer to similar treatment, but the roots must be well moistened with water at a temperature of about 85 degrees when started.—F. JORDAN, Warter Priory Gardens.

THE FLOWER GARDEN.

MICHAELMAS DAISIES.—Among autumn-flowering plants Michaelmas daisies have pre-eminence for their free-flowering and decorative qualities, and their diversity of habit makes them a very interesting group, which is being added to annually by new varieties of merit. Perhaps the greatest break away from the ordinary character was the raising of a variety with flowers of double form, named Beauty of Colwall; but, unfortunately, it has this season been somewhat disappointing, showing a tendency to come single. The Michaelmas daisy is one of the most long-suffering of plants, and also one which responds most readily to good cultivation. It is used in various ways, and is very adaptable. Here good clumps of the Amellus varieties, placed towards the front of the border, are very effective, and many of the Novi-Belgii varieties afford us splendid subjects for the back, and of these the variety Climax is one of the best. The other types are no less attractive than those mentioned, and should be represented in all borders where an autumn display is desired. The stronger-growing varieties are often used successfully in the semi-wild garden, but perhaps under no conditions are they seen to a better advantage than when a good collection has a site to itself. But, in whatever manner they are used, the cultural requirements amount practically to the same. Some growers adopt the method of rooting young plants in the spring, and planting them out singly, two to three feet apart each way. The practice is a good one when well developed sprays are required for exhibition and other purposes, but, as a general rule, they are grown in clumps. With the exception of some of the Amellus type, most varieties spread freely and soon become overcrowded; to avoid this I advocate lifting the clumps at least every second season, and reducing them proportionally to the vigour of the variety before replanting. The present time is most suitable for undertaking such work and for the opportunity it offers of enabling the ground to be deeply dug and manured.

CHRYSANTHEMUMS.—This season has been an exceptional one for outdoor chrysanthemums. As the plants pass out of flower cut back the tops to within a foot of the ground, and afterwards lift the stools and place them closely together in a cold frame, covering the roots with leaf-soil; they are then safe from all risk of loss through the winter, as in some districts none but the hardiest varieties can be relied on to stand in the open ground. This procedure also ensures an abundance of cuttings for propagating early in the New Year.

PLANTING.—Every effort should be made to complete all planting connected with spring bedding by the middle of the month, and it is always advisable at this season, when we expect but few drying days, to plant up the ground directly it has been prepared, as then the soil is in a better working condition than if left to get wet again before planting. The same remarks apply to planting bulbs, as, under natural conditions, their roots would at this season be very active, and this convinces us of the importance of bringing the work to a finish as early as possible.—T. B. FIELD, Wych Cross Place Gardens.

EXHIBITIONS AND MEETINGS.

Southampton.

OCTOBER 28 and 29.

The annual autumn show, held in the Coliseum, was a great success, and though the entries were fewer than in some years the exhibits were of average quality. Japanese and single-flowered varieties were at their best, and trade exhibits were numerous and interesting.

PLANTS.

For five plants suitable for conservatory decoration, distinct, each to carry not less than five blooms, two competed, and Mr. F. G. Bealing, The Nurseries, Bassett, Southampton, was easily first with plants more remarkable for the good quality of the flowers than their number; varieties like Frances Joliffe, Mrs. R. Luxford, Mrs. Miller, and F. S. Vallis, each carried six to eight specimen blooms and good foliage; Mr. C. Hosey, gardener to J. C. E. D'Esterre, Esq., Southampton, second.

Single-flowered varieties were not numerous; Mr. Allan Cooper, 115, Hill Lane, Southampton, was first with really good plants; and Mr. Bealing second. Naturally-grown bush plants were a fine feature of the show. Mr. Hosey, with 4-feet diameter plants of Yellow Cap, White Cap, and Pink Cap, grandly flowered, came first; Mr. Bealing third; second prize withheld.

Amateurs staged really fine plants of Japanese varieties, and Mr. Allan H. Hill, London Road, Southampton, was a creditable first prize-winner.

CUT BLOOMS.

The leading class was for eight Japanese, distinct, three blooms of each, in vases. Four competed, and Mr. W. Baxter, gardener to Captain Dalgety, Lockerly Hall, Romsey, was an easy first, with full, richly-coloured, fresh examples of Master James, Lady Talbot, F. S. Vallis, W. Turner, D. B. Crane, Eclipse, Frances Joliffe, and Mrs. T. Stevenson. Mr. Bealing was second with smaller flowers; and Mr. Hosey third.

For any two varieties other than white, three of each, four competed, and Mr. Baxter led with grandly-developed blooms of F. S. Vallis and Mrs. H. Luxford; Messrs. Bealing and Hosey followed in the order here given. For two varieties of any white-flowered Japanese, three blooms of each, there were but three entrants. Mr. Hosey won the premier place with W. Turner and Mrs. Marsham; Mr. Bealing second.

A class was provided for six blooms of two incurved, and two of any other decorative variety, distinct, excepting singles, in vases. Mr. Bealing won easily with handsome, well-arranged blooms of Mrs. H. Luxford, H. W. Thorpe, and Clara Wells; Mr. T. Hall, gardener to Ellen Lady Swaythling, South Stoneham House, second. For four vases of decorative varieties, distinct, not less than three blooms to a spray, singles excluded, Mr. G. Ellwood, gardener to W. H. Myers, Esq., Swanmore House, Bishop's Waltham, was easily first, with huge sheaves of Kathleen Thompson, Yellow Source d'Or, Caprice du Printemps, and Mrs Marsham; Mr. Bealing second.

Single varieties disbudded and not disbudded were numerous and good. In the former section Mr. Bealing had the best set of six varieties amongst four entrants, with grandly-developed specimens of Mensa, Yellow Pagram, J. B. Lowe, G. Trowers, Merstham Gem, and Ellen Neville; Mr. C. Hooney, gardener to J. T. Rayner, Esq., Boscombe, a good second. Mr. Hall claimed the premier award in the latter division with well-developed blooms of such desirable varieties as Mary Richardson and Ceddie Mason. Messrs. Bealing and Cooper second and third in the order given.

Amateurs made a fine display. Mr. A. H. Hill won for twelve Japanese, in four varieties, and his King George, Rose Pockett, and J. H. Silsbury were very good.

In the open class for twenty-four Japanese, on boards, not less than sixteen varieties, or more than two of any one variety, there were but three entries, Mr. Baxter being easily first with almost perfect blooms of F. S. Vallis, Eclipse, F. Jolliffe, Mrs. R. Luxford, Lady Talbot, and Master James; Mr. Bealing second with much smaller specimens; Mr. Hall third. Twelve Japanese, distinct, were only shown by two exhibitors; Mr. Hosey first; Mr. A. F. Tofield, Holmesdale, Chandlers Ford, second. Twelve incurved varieties, distinct, were poorly shown in the open classes, but in the amateurs' division they were of a superior order. Mr. A. H. Hill staged a remarkable dozen, such varieties as Romance, C. H. Curtis, W. J. Higgs, Emblème Poitevine, Clara Wells, and C. E. Harrison being noticeable as the best in the first prize stand; Mr. Tofield second with less refined blooms.

The premier award for the best incurved bloom in the show was granted to a huge specimen of Miss Cora Stoop. The premier Japanese bloom in the open classes was a grandly-developed specimen of F. S. Vallis in Mr. Baxter's stand. Mr. Tofield secured a like award in the amateur section with W. Turner.

Tables of cut chrysanthemums, with autumn foliage, were interesting, Mrs. Bealing winning with bronze flowers and suitable foliage.

Baskets of autumn foliage, berries, etc., were attractive, and Mrs. Ladhams, Shirley, won the premier position with Oak, Berberis, Guelder Rose, etc., all harmoniously arranged.

FRUITS AND VEGETABLES.

Fruits were not numerous, but of good quality. For two bunches of black grapes, Mr. G. Ellwood led with Mrs. Pince; Mr. Hall following with the same variety. In the class for Alicante, Mr. G. Ellwood again secured the leading position, as he did for one bunch of any black variety. Mr. Baxter showed the best two bunches of white grapes, handsome examples of Muscat of Alexandria; Mr. Ellwood following with the same variety.

For four varieties of dessert apples, the Locksheath Nursery Company, Locksheath, were first with handsome examples of Cox's Orange Pippin, Gravenstein, Allington Pippin, and Cornish Aromatic; Mr. Ellwood second. Mr. Hall won for four dishes of kitchen varieties with huge specimens of Peasgood's Nonsuch, Warner's King, and Mère de Ménage; Mr. Ellwood second.

Vegetables were a strong feature. Messrs. Toogood and Sons offered prizes for six dishes, distinct. Ten competed, and Mr. Ellwood was easily first with grandly developed leeks, celery, onions, tomatoes, and potatoes; Mr. H. Keep, Aldermaston, Reading, second. In a stiff competition Mr. Ellwood also won first place in the classes provided by Messrs. Sutton and Sons and Messrs. Carter and Co., with similar produce.

NON-COMPETITIVE.

Trade exhibits were numerous. Messrs. Sutton and Sons, Reading, staged eighty dishes of high-class vegetables (Gold Medal). Messrs. Toogood and Sons, Southampton, also displayed vegetables of a high-class character (Gold Medal). Messrs. Rogers and Sons, Bassett Nurseries, Southampton, had an attractive collection of roses and apples (Gold Medal). Mr. E. Wills, Winchester Road Nurseries, Southampton, had a remarkable exhibit of floral designs, along with a choice assortment of well-grown market plants (Gold Medal).

Messrs. W. Wells and Co., Merstham, Surrey, displayed chrysanthemums of a high order of merit, and conspicuous in this group was the new "Daily Mail" variety, a yellow Japanese; single-flowered varieties also were well represented (Gold Medal). Mr. E. J. Wootton, Fair Oak, Eastleigh, had an interesting collection of carnations and violets (Silver Medal). Mr. C. Dymott, Freemantle Nurseries, Southampton, arranged an attractive group of well-grown dwarf chrysanthemums (Silver-gilt Medal). Messrs. Jarman and Co., Chard, had dahlias, roses, and apples; and Messrs. B. Ladhams and Sons, Shirley, Southampton, arranged an attractive exhibit of herbaceous plants, alpines, roses, etc.

Bournemouth.

OCTOBER 28 and 29.

On the above dates the Bournemouth Horticultural Society held its annual autumn exhibition in the Westover Skating Rink, one of the largest halls in the country, and this was well filled with magnificent exhibits and formed an ideal place for such a display. The groups and cut blooms, the fruit (especially the grapes), and vegetables in the competitive section, and the groups shown by Messrs. G. Watts and Sons, Lim., Messrs. John Waterer and Sons, Messrs. Stuart Low and Co., and Messrs. J. Carter and Co., of Raynes Park, in the non-competitive section, were the outstanding features of the show.

GROUPS.

In the class for a group of miscellaneous plants and cut flowers, Mr. Usher, gardener to Sir Randolph Baker, Bart., Ranston, Blandford, was the winner. Very fine crotons with some orchids and palms were used to great advantage, but the poinsettias at the crown rather hid the palm, and gave a heavy appearance. Messrs. G. Watts and Sons, Lim., Palace Nurseries, Bournemouth, were second with a lovely group, in which every plant was neatly arranged. Mr. J. Stevenson, Wimborne, won third position with a charming group, in which autumn tints blended harmoniously. The challenge cup also went to Mr. Usher. Mr. Pearce, gardener to Mrs. Ormond, Bournemouth, won first prize and cup in the class for a group of Japanese and single-flowered chrysanthemums.

CUT BLOOMS.

Mr. J. H. Tooley, gardener to Mr. Andrews, Winchcombe, won the first prize of £5 with a lovely stand of Japanese cut blooms; Master James, Queen Mary, His Majesty, Alice Lemon, Francis Jolliffe, Kara Dow, Lady Talbot, and Mrs. Lopes were the best flowers—a very even stand of clear colours. The second place was secured by Mr. Usher, who had Bob Pulling, F. S. Vallis, Mrs. A. E. Roope, Mr. Turner, and D. B. Crane in grand condition. Mr. B. Dacre, gardener to Mr. W. Dickinson, Taunton, was a close third, and Pockett's Crimson and Master James were fine blooms in this stand.

In the class for twelve Japanese incurved blooms, Mr. Usher was the winner, and he had fine examples of W. Turner, E. Davis, H. E. Converse, Mrs. R. Pulling (almost green), and Mrs. A. E. Roope; second and third honours went to Mr. Dacre and Mr. Tooley in the order named.

The blooms in vases made an imposing display. For nine Japanese, distinct varieties, three blooms in each vase, Mr. H. Woollman, Shirley, Birmingham, was well first; he had Alice Lemon, C. H. Gotty (grand), Mrs. A. T. Miller, Lady Crisp, Miss Gladys Herbert, Thos. Lunt, Lady Talbot, Kara Dow, and Mrs. Lloyd Wigg, in splendid condition. Mr. J. Stevenson was a good second, and third honours went to Mr. Tooley. In the class for two vases, nine blooms in each, two varieties, Mr. E. G. Cox, gardener to Mrs.

Duberley, Bournemouth, was first, and won the handsome cup which was offered in this class. Mr. Kitcher, gardener to Major Wyndham Pain, Christchurch, was placed second.

Mr. Galpin, gardener to Mrs. Telfer, had the best six vases, distinct, three blooms in a vase. He also won in the class for one vase of Japanese, yellow; Mr. Cox winning in the other class for six Japanese, white. Mr. Honey, gardener to Mr. J. G. Rayner, had a grand lot of singles, winning in the class for six vases; Mr. Barge, gardener to the Rev. C. H. Burrows, being successful in another class for singles.

FRUIT AND VEGETABLES.

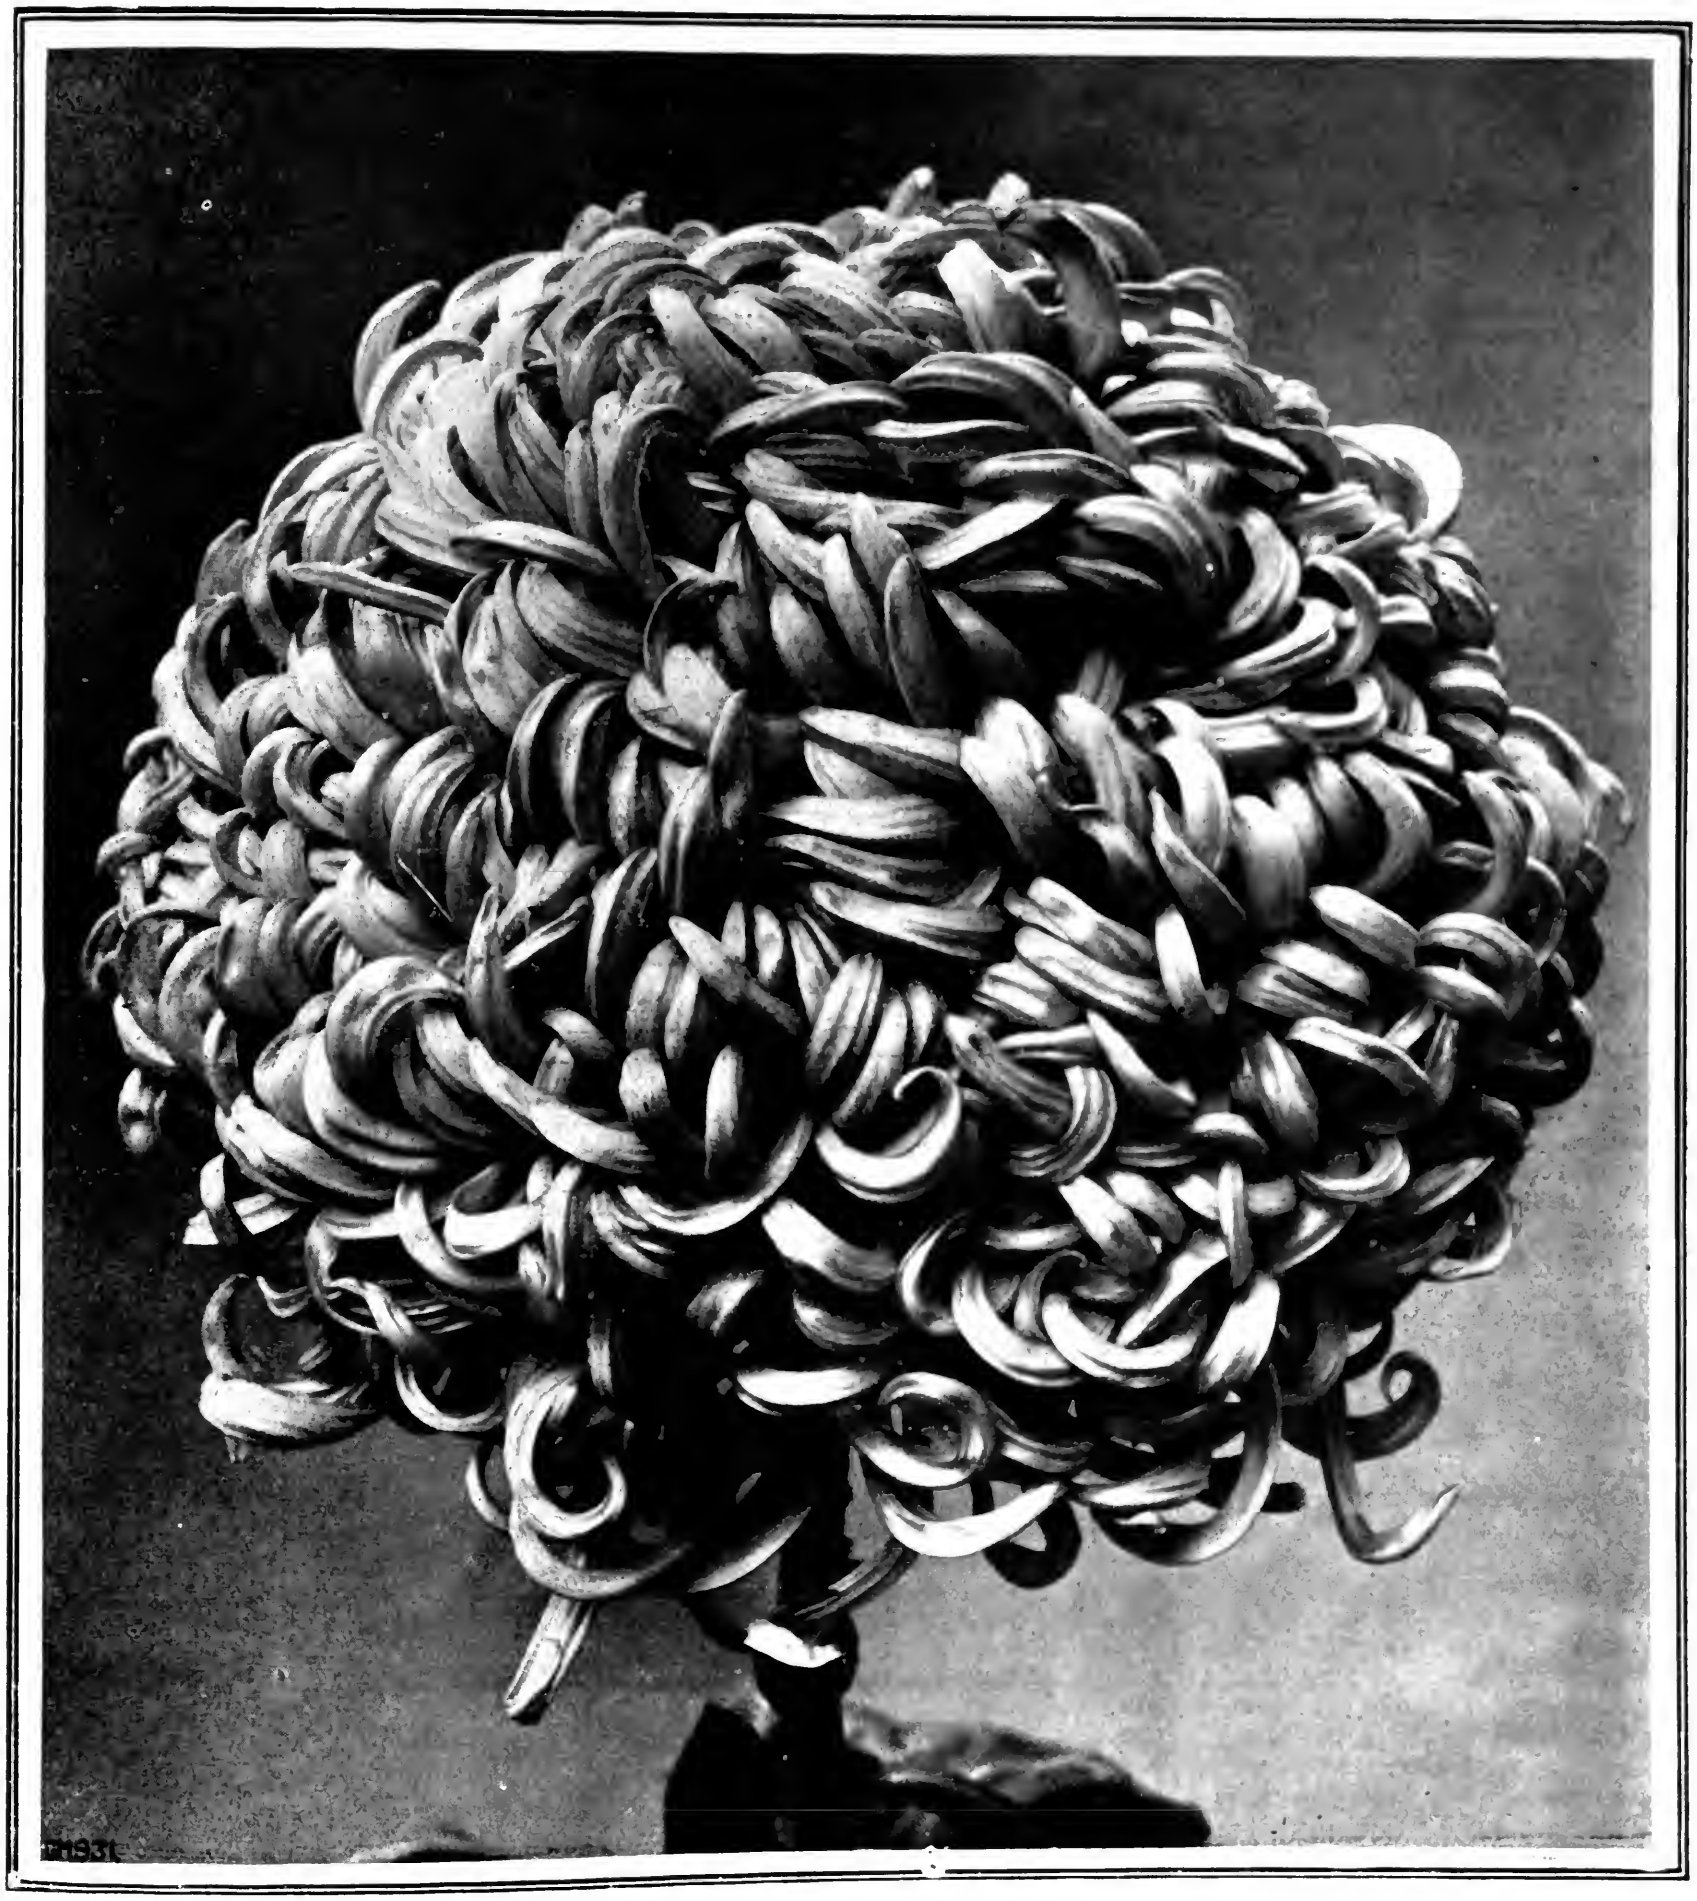
Forty-five bunches of grapes were staged, the quality of the Muscats being very high. Mr. Hall, gardener to Major Chichester, Romsey; Mr. Hill, gardener to Mrs. Banks, Wimborne; Mr. Tooley, and Mr. Barrett, gardener to Mr. H. May, Bournemouth, were the principal winners. Messrs. Copp, Dacre, Hill, Cape, and Usher were the chief prize-winners in the apple and pear classes. The last-named won in the classes for collections of vegetables, the prizes being offered by Messrs. Sutton and Sons, Messrs. Webb and Sons, and Messrs. Toogood and Sons.

Royal Horticultural Society.

Despite the fog that hugged London like a wet blanket on Tuesday morning last, there was another capital show at the Royal Horticultural Hall, and, as the day wore on and the sun dispersed the fog, the attendance became so large as to render an inspection of the exhibits difficult. Chrysanthemums and orchids, vegetables and fruits were the outstanding features, but dahlias were still in evidence, and carnations were excellent.

CHRYSANTHEMUMS.

Chrysanthemums were a great feature of



CHRYSANTHEMUM DAILY MAIL.

Colour soft yellow. F.C.C., N.C.S., October 27. A.M., R.H.S., November 4. Messrs. W. Wells and Co.

OTHER FLOWERS AND PLANTS.

Zonal pelargoniums made a brilliant display. Mr. Heath, gardener to Mr. G. G. Russell, won with a grandly-grown collection, and he now has eight successive wins in this class, but he was closely followed by Mr. Webb, gardener to Doctor Ramsay, Mr. Weaver being third.

Mr. Short, gardener to Mrs. Watkins, Parkstone, won the cup offered in the class for a group of begonias and other winter-flowering plants.

NON-COMPETITIVE.

Gold Medals.—Messrs. G. Watts and Sons, for hardy plants, chrysanthemums, and floral designs; Messrs. Stuart Low and Co., Enfield, for orchids and carnations; Messrs. John Waterer and Sons, Bagshot, for hardy plants, shrubs, and climbers; Messrs. James Carter and Co., Raynes Park, for vegetables.

Silver Medals.—Mr. J. J. Kettle, Corfe Mullen, for violets; Mr. R. Chamberlain, for floral designs; and Messrs. Toogood and Sons, Southampton, for vegetables.

the display. A large sloping bank just inside the entrance doors, set up by Mesrs. Jas. Veitch and Sons, Chelsea, was a great attraction. It consisted wholly of pot plants, and chiefly of dwarf, bushy specimens in 48-sized pots, each carrying from a dozen to a score of good-sized blooms—just the stuff for home or conservatory decoration. Caprice du Printemps and its varietal forms, known for the sake of brevity as Red Cap, Purple Cap, White Cap, and Yellow Cap, were those most in evidence, but Kathleen Thompson, Joan

Manor Street, Hull.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

Edwards, Primrose Girl, and Master Rex were equally good; at the back were fine big blooms of Mrs. H. J. Jones, Mrs. A. T. Miller, and other Japanese varieties. In another part of the hall the Chelsea firm presented a large group of such fine winter-flowering begonias as Agatha, Winter Cheer, Emita (very brilliant), Winter Perfection, Fascination, Mrs. Heal, Exquisite, Optima (very bright), and Elatior.

A great feature of the meeting was the "Jones' Avenue" of chrysanthemums. Messrs. H. J. Jones, Ryecroft, Lewisham, filled both sides of one long gangway, and were deservedly awarded a gold medal for an unique and glorious display. Against a white paper background, Mr. Jones arranged splendid stands of fine flowers of high-class Japanese varieties, with low bowls of single and decorative varieties in the foreground. Autumn foliage was associated with the blooms. A few of the outstanding large-flowered sorts on view were Bob Pulling, the biggest flower; Mrs. R. C. Pulling, Mr. H. J. Jones, Mrs. Howard Kinsey, Mrs. E. Tickle, Mrs. F. W. Smith, Mary Hollert, Jones Stratton, His Majesty, Elsie Davis, J. Surrey, and Lord Airlie; the best singles were Hector Menzies, Mrs. Harry Wood, Mrs. Herbert Weller, Miss Dorothy Weedon, Florrie King, and Arthur. A most comprehensive exhibit, including representatives of all sections from the tiniest pompons to the biggest Japanese varieties.

The Messrs. Price and Fyfe, Grove Park Nursery, Lee, put up a very bright lot of chrysanthemums, associating the flowers pleasingly with autumn-tinted foliage. Messrs. Whitelegg and Page, Chislehurst, presented an imposing exhibit of single and decorative chrysanthemums, and set up bold masses of Mrs. Leonard Harrison, Miss M. Bower, F. Andrews, Master Arthur Chapman, Cannell's Crimson, and other fine single varieties.

Messrs. W. J. Godfrey and Son, Exmouth, displayed chrysanthemums, and made a feature of their single varieties Devonshire Lass, pink; Miss Margaret Gidley, orange-buff; Mollie Godfrey, deep rose; and Excelsior, orange. Messrs. Reamsbotham and Co., Geashill, King's Co., Ireland, showed pompon and decorative chrysanthemums. Messrs. W. Wells and Co. made a bold display of chrysanthemums, and secured awards of merit for The Daily Mail and Madame Theresa Morel, Japanese varieties; Golden Mensa, a fine yellow single; and for the vivid scarlet perpetual carnation named Champion.

HARDY PLANTS AND DAHLIAS.

Messrs. J. Cheal and Sons, Crawley, brought up an interesting collection of cut sprays of ornamental trees and shrubs, selected chiefly for their autumn effects; acers, azaleas, rhus, thorns, spiræas, plums, and beeches were well represented, while veronicas, ceanothuses, heaths, and Daboccia polifolia were flowering subjects; a really good display of dahlias, including the pink Crawley Star, was remarkable for such a late date. Messrs. Pipers, Bayswater and Barnes, filled a corner of the hall with pæony-flowered dahlias set up boldly on tall stands; the flowers showed the effects of the weather, but were nevertheless remarkable for November 4, King Leopold, Ryton Roy, Romolo Piazzani, Cæsar, and Geisha being especially fresh and clean.

The Wargrave Hardy Plant Farm, Lim., The Arcade, Liverpool Street, presented a little rock garden, furnished with diminutive conifers and colonies of Mazus rugosus, Linaria cymbalaria globosa, Plumbago Larpentæ, Polygonum vaccinifolium, P. capitatum, and the white-berried Margyricarpus setosus. Mr. G. Reuthe Keston, had many interesting hardy plants on view, notably Aster Tradescanti, Desfontainia spinosa, autumn crocuses, colchicums, Nerine flexuosa, alba, N. Mrs. Gunther, and Schizostylis coccinea.

Messrs. R. Wallace and Co., Colchester, showed fruiting branches of Decaisnea Forgeti, with their long, bean-like, fleshy, bright purple fruits; and also submitted Iris Vartani White Pearl (A.M.), a very beautiful dwarf iris. Messrs. Barrie and Brown, King William Street, London Bridge, showed berried shrubs, chief interest centring in the pernettyas and Gaultheria purcumbens. Mr. Du Cane Godman, South Lodge, Horsham, exhibited Kniphofia multiflora, a white, late-flowering species referred to elsewhere in this issue.

Mr. Clarence Elliott, Stevenage, showed small conifers suitable for the rock garden and colonies of saxifrages, sedums, plumbago, and gentians. Messrs. Thos. S. Ware contributed a quite brilliant lot of dahlias, Schizostylis coccinea, Kniphofia Modesta, a slender-spiked, white-flowered species, and selections of alpines. Messrs. Thompson and Charman, Adelphi, W.C., presented alpine plants in great variety.

Mr. G. Prince, Longworth, was the only exhibitor of roses, and his little group was greatly admired, as the flowers were both fresh and fragrant.

GREENHOUSE PLANTS AND CARNATIONS.

Messrs. W. Cutbush and Son, Highgate, showed their carnations on a table, and, in addition to well-known sorts, set up the bright purple Madame Barrain, the red-flaked Mrs. Tatten, Mrs. W. Aster, buff and scarlet, and Mrs. L. D. Fullerton, heliotrope and red. Winter-flowering begonias from the same firm filled a long table. Heaths, solanums, dwarf, bushy chrysanthemums in small pots, winter-flowering begonias, the lovely Selaginellas cæsia, and ferns made up an interesting display from Messrs. H. B. May and Sons, Edmonton.

Mr. S. Mortimer, Farnham, exhibited carnations and a batch of the perpetual stock All-the-Year-Round, a fragrant white variety. Mr. L. R. Russell, Richmond, made up a really first-rate display of ornamental stove foliage plants. Crotons, dracænas, marantas, palms, alocasias, ficus, and aralias were freely staged in great variety.

Messrs. Allwood Brothers, Haywards Heath, put up stands of beautiful flowering perpetual carnations, and were particularly successful with their blooms of Mary Allwood, perpetual Malmaisons, Cinderella, Mandarin, Enchantress Supreme, and Wivelsfield White. Gorgeous (A.M.), a new cerise-scarlet perpetual carnation, broad-petalled and full, was finely shown by Messrs. Stuart Low and Co., Enfield, with other varieties of this section.

Messrs. Wills and Seegar, Onslow Terrace, Kensington, exhibited fine specimens of Begonia Gloire de Lorraine in ornamental tubs and vases.

ORCHIDS.

A handsome group of orchids from Messrs. Charlesworth and Co., Haywards Heath, was a fine feature, and it contained Epidendrum vitellinum majus, fine odontiodas, ondontoglossums, cypripediums, Cattleya Tityus, very fine, C. Fabia, and C. Fabia alba, C. Enid, C. Venus, and other useful late-flowering orchids. Oncidia Cooksonæ, a fine form, was sent by Mr. C. J. Phillips, Sevenoaks, and Mr. Hunter, gardener to the Duke of Marlborough, Blenheim, brought up several good things, notably Lælia-cattleya Olenus Blenheim var. (A.M.), rich crimson-purple, with royal purple lip.

Sir Trevor Lawrence, Bart. (grower, Mr. W. H. White), Burford Lodge, Dorking, had finely-grown specimens of Cœlogyne fimbriata, Cattleya Fabia, and Sigmatostylax radicans, and gained two cultural commendations. Messrs. Flory and Black, Slough, and Messrs. Waters Butler, Edgbaston, Birmingham, each showed a few orchids. R. G. Thwaites, Esq., Streatham, brought the dainty white cattleya hybrid and some odontiodas. Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), submitted Cypripedium Olympus (A.M.), a very bold form with a wide, white green-based dorsal sepal; Odontioda Latona Westonbirt var., and Odontoglossum crispum xanthotes Westonbirt var. (A.M.), white with golden spots.

Mr. J. Collier, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate, showed a dozen and a-half flowering plants of Cattleya Portia cærulea, the blue tinted hybrid obtained by crossing C. Bowringiana violacea and C. labiata cærulea; the two parents were also represented, and added to the interest of the group. A pleasing group of orchids from Messrs. Armstrong and Brown, Tunbridge Wells, contained good examples of Cattleya Bowringiana, C. Mantini, C. Fabia, C. Armstrongæ, C. Mrs. Pitt, Brasso-cattleya Maronæ, Lælio-cattleya Berthe Fournie, and numerous cypripediums, odontoglossums, and odontiodas.

The orchids from Mesrs. Sander and Sons, St. Albans, included Cattleya Hardyana, C. Sylvia, C. Fabia, Cypripedium insigne Harefield Hall, Cymbidium erythrostylum, Brasso-cattleya Mrs. Leemann, Cirrhopetalum Rothschildianum, and the deep-hued Odontioda Charlesworthi, The Comet. Orchids were well shown by Messrs. Stuart Low and Co., Enfield, and the group included Phalænopsis Rimestadiana, Vanda cærulea in some quantity, Oncidium varicosum, Cattleya Fabia, C. labiata, and the lovely Brasso-cattleya Leeanæ.

Messrs. Hassall and Co., Southgate, showed the pretty Cypripedium Niobe, Cattleya aurea, the lovely white-petalled C. Sylvia, C. Pittæ, and other good things. From Messrs. J. and A. McBean, Cooksbridge, came many good things, including Cymbidium Doris and the beautiful gold and mauve Cattleya Andriana McBeans var. (A.M.). Messrs. J. Cypher and Sons, Cheltenham, brought up some interesting cypripediums, Cattleya Pittæ, C. labiata, C. Bowringiana, and C. Minneia.

VEGETABLES AND FRUIT.

A splendid exhibit of seventy-two baskets of finely-selected potatoes was made by Messrs. Dobbie and Co., Edinburgh. In all there were about forty varieties. In the matter of display this was a particularly handsome exhibit, and in the matter of cultivation the potatoes were first class. Such varieties as Dobbie's Prolific, Great Scott, Burhouse Beauty, a white, pebble-shaped variety to be sent out in 1914; The Favourite, Midlothian Early, The Chapman, Windsor Castle, The Factor, British Queen, Conquest, King Edward VII., Erin's Queen, and Sutton's Abundance were specimens of what high-class potatoes should be. The unwashed tubers attracted quite as much attention as the carefully-cleaned ones.

A grand lot of finely-coloured apples, shown by Messrs. W. Seabrook and Sons, Chelmsford, was greatly admired. Mr. Paskett, gardener to E. J. Johnstone, Esq., Burrs Wood, Groombridge, submitted about sixty dishes of well-coloured apples, including the leading dessert and culinary varieties. Mr. Divers, gardener to the Duke of Rutland, Belvoir Castle, Grantham, sent about thirty-six dishes of pears, which included excellent examples of Easter Beurre, Pitmaston Duchess, Catillac, Durondeau, Beurre Hardy, etc.

AWARDS OF MERIT.

No First Class Certificate was granted on this occasion.

Award of Merit.—To Chrysanthemum Daily Mail, Golden Mensa, Madame Theresa Morel, and Carnation Champion, from Messrs. W. Wells and Co., Merstham; to Chrysanthemum Pink Pearl, from Messrs. H. J. Jones, Lewisham; to Carnation Gorgeous, from Messrs. Stuart Low and Co., Enfield; to Iris Vartani White Pearl, from Messrs. R. Wallace and Co., Colchester; to Cypripedium Olympus, and to Odontoglossum crispum xanthotes Westonbirt variety, from Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury; to Cympedium Stella, from Messrs. Sander and Sons, St. Albans; to Lælio-cattleya Olenus Blenheim var., from the Duke of Marlborough (gardener, Mr. Hunter), Blenheim; to Sophro-lælio-cattleya Niobe, from Messrs. Charlesworth and Co., Haywards Heath; to Cattleya Andriana, McBean's var., from Messrs. J. and A. McBean, Cooksbridge.

MEDALS.

Gold.—To Messrs. Dobbie and Co., Edinburgh, for potatoes; to Messrs. H. J. Jones, Ryecroft, Lewisham, for chrysanthemums.

Silver-gilt Flora.—To Messrs. Jas. Veitch and Sons, Chelsea, for begonias and chrysanthemums; to Messrs. Charlesworth and Co., Haywards Heath, for orchids.

Silver Flora.—To Messrs. W. Cutbush and Son, Highgate, for begonias and carnations; to Messrs. Price and Fyfe, Lee, for chrysanthemums; to Mr. L. R. Russell, Richmond, for stove plants; to Messrs. Thos. S. Ware, Feltham, for dahlias and alpines; to Messrs. Stuart Low and Co., Enfield, for orchids; to Messrs. Armstrong and Brown, Tunbridge Wells, for orchids.

Silver Knightian.—To Mr. Paskett, gardener to E. J. Johnstone, Esq., Groombridge, for hardy fruits; to Mesrs. W. Seabrook and Sons, Chelmsford, for apples.

Silver Banksian.—To Messrs. J. Cheal and Sons, Crawley, for autumn foliage and dahlias; to Messrs. H. B. May and Sons, Edmonton, for greenhouse plants; Messrs. Sander and Sons, St. Albans, for orchids; Sir Jeremiah Colman, Bart. (gardener, Mr. J. Collier), Gatton Park, Reigate.

Bronze Banksian. — To Messrs. Allwood Brothers, Haywards Heath, for carnations; to Messrs. Stuart Low and Co., Enfield, for carnations; to Messrs. Pipers, Bayswater and Barnes, for dahlias; to Mr. G. Reuthe, Keston, for hardy plants; to the Wargrave Hardy Plant Farm, Lim., The Arcade, Liverpool Street, E.C., for alpines, etc.; to Mr. George Prince, Longworth, for roses; to Messrs. J. Cypher and Sons, Cheltenham, for orchids.

Bronze Flora.—To Messrs. W. Cutbush and Sons, for begonias and carnations.

SCIENTIFIC COMMITTTEE.—October 21.

Present: Mr. E. A. Bowles, M.A., F.L.S., F.E.S. (in the chair); Messrs W E. Ledger, A. Worsley, W. C. Worsdell, J. Fraser, W. Hales, F. J. Chittenden (hon. secretary), and R. Farrer (visitor).

PELARGONIUM HYBRIDS — Mr. J. Fraser continued his observations upon the origin of the garden varieties of scented-leaved pelargoniums, dealing mainly with the varieties of P. citriodorum nearly allied to P. crispum. His full report will appear in the "Journal" of the society.

PHASEOLUS CARACALLA. — Mr. Chittenden showed the flowers of this curious East Indian plant, with their curled keels looking very like snails, so that the plant has been called the Snail flower. The specimens came from Hampton Court, where the plant was introduced in 1690.

LOBELIA HYBRIDS. — Mr. Arkwright sent specimens of a hybrid between Lobelia cardinalis and L. syphilitica. The plants, which were tall, varied in the colours of their flowers and in the shades of their foliage. They gave promise of developing into handsome garden plants, though the colours were a little dingy at present. This may have been due, in part at least, to the late season of their flowering, and to the fact that they had been brought on in a greenhouse. The name L. × Arkwrighti was proposed for them.

Torquay Chrysanthemum Show.

The Torquay District Gardeners' Association held their annual show in the large hall of the Bath Saloons at Torquay on October 30. The weather was unfortunately wet, and the attendance was therefore somewhat meagre, but the exhibits were of high order of merit, many of the plants and flowers shown being particularly fine, while the entries left little to be desired.

For a group of single chrysanthemums the first prize and the National Chrysanthemum Society's certificate was won by Colonel Cary. In the class for twenty-four Japanese cut blooms, Mr. W. J. Godfrey, of Exmouth, obtained the premier award with a splendid collection of blooms, and his Lady Talbot was awarded the National Society's medal for the best bloom in the show. Other fine blooms in the stand were F. S. Vallis, Eclipse, F. Rowe, and J. Lock. For twelve Japanese distinct, in vases, the premier award was made in favour of Mr. R. S. Dugdale, whose Lady Talbot, Mrs. H. Stevens, W. Turner, and F. Joliffe were excellent. For eighteen Japanese, Colonel Cary was first with F. Chandler, Mrs. R. Luxford, Thorp's Beauty, A. T. Miller, and R. B. Crane, very good. For six Japanese, Mrs. Cogan was first with Hon. Mrs. Lopes, Mrs. Peed, and Mrs. Joliffe, very fine. For twelve Japanese, Colonel Cary was first, and also six Japanese, yellow, Colonel Cary first, with F. S. Vallis; six Japanese, white, Mrs. Cogan, first; for six Japanese, any one variety, Colonel Cary first; for six vases of single chrysanthemums, six varieties, Mr. W. F. Baynes first; vase of cut chrysanthemums, double, Mr. F. Perret first; vase of cut chrysanthemums, single, Mr. W. F. Baynes first; basket of wild flowers, with foliage and berries, Mr. F. Perret first.

In competition for the prizes for three trained chrysanthemums, single, Colonel Cary first, the same exhibitor being first also for three trained chrysanthemums, double. These were exceptionally fine plants. For six table plants, flowering, Dr. Leon was first with beautiful examples, and in the class for six table plants, foliage, Colonel Cary occupied the first place. Mrs. Cogan obtained premier honours for six winter-blooming begonias. For three solanums, Mr. S. T. Gitsham was first.

Nurserymen's exhibits added much to the attractions of the show. The Devon Rosery, Torquay, had an attractive stand, with numbers of fine chrysanthemums, Erica melanthera, E. nivalis, E. gracilis, Lilium longifolium, Begonia Gloire de Lorraine, Ceanothus Gloire de Versailles, Rose Jessie, Rose Orleans, Allamanda Hendersoni, and some wonderfully good apples, amongst which Blenheim Pippin, Bramley's Seedling, Bismarck, Golden Noble, Warner's King, and Sandringham were especially fine. Messrs. R. Veitch and Son, Exeter, showed a very interesting collection of plants, winter-flowering carnations being well represented by Brightness, Benora, Orpheus, Mrs. T. M. Crook, My Favourite, Mrs. C. Page, Princess Juliana, Mrs. C. F. Raphael, Sunstar, Cinnabar, La Mode, British Triumph, Mrs. Greswolde Williams, Lady Meyer, and Baroness de Brienen. Violets were well shown, and included Kaiser Wilhelm, St Helena, Luxonne, Noelie, Admiral Avellan, California, Baroness Rothschild, and Comte de Brazza. Other plants included Cyrtanthus hybrida, Nerine Bowdeni, N. Exonia, Clematis Nellie Moser, and Gloriosa superba. Mr. W. B. Smale, Torquay, exhibited Erica hyemalis, Datura suaveolens, Acalypha Sanderi, Salvia fulgens, Rhodochiton volubile, Cyclamen, and a collection of cactus dahlias, amongst which were Snowdon, Excelsior, Fairy, Victorian, Ariel, Devonshire Maid, and Major Hobbs.

National Chrysanthemum Society.

(Continued from page 838.)

Mr. A. Dyer, gardener to E. Wood, Esq., Upper Norwood, showed the finest vase of decorative chrysanthemums, and he was also a good first for a vase of single flowers, besides scoring for six blooms of one incurved variety with Clara Wells.

In other classes the leading competitors were Mr. W. Gooding, Mr. Tofield, Mr. Campkin, Southend-on-Sea; Mr. E. A. Foster, Shrewsbury Lane, Woolwich; and Mr. Loo Thomson.

FRUIT.

In the fruit classes Mr. A. Jefferies, gardener to J. Balfour, Esq., Moor Hall, Harlow, led for black grapes with three fine bunches of Appley Towers; Mr. W. Howe, gardener to Lady Tate, Streatham Hill, second; and Mr. E. C. Wickens, gardener to C. Bayer, Esq., Tewkesbury Lodge, Forest Hill third. Mr. Wickens was first in the class for Gros Colmar grapes. Mr. Jefferies

By Special Appointment to His Majesty the King.

MESSRS. JAMES VEITCH & SONS, LTD.

Royal Exotic Nursery, CHELSEA.

Beg to announce that they are still carrying on every branch of their NURSERY BUSINESS for the supply of plants, trees, shrubs, vines, and fruit trees, etc., at their Chelsea, Coombe Wood, Langley, and Feltham Nurseries. An inspection is invited.

led also for white grapes with long bunches of Muscat of Alexandria; Mr. J. Simon, Ravenswood, Bexley, second; and Mr. Wickens, third.

The leading prizewinners in the apple classes were Mr. James Whittle, gardener to Colonel Borton, Cheveney, Hunton, Maidstone; Mr. A. Basile, Woburn Park Gardens, Weybridge; and Mr. W. Lintott, Morden Park Gardens, Caterham.

NON-COMPETITIVE.

Messrs. W. Wells and Co., Merstham, surpassed themselves on this occasion by filling a space 72ft. long by about 10ft. with all sorts of chrysanthemums. They had representatives of practically all sections of chrysanthemums, and set up altogether about seventy varieties of singles, about sixty of Japanese, a dozen incurved, and a few pompons. The group was high pitched, and at the back, with palms and scarlet oak foliage, were tall stands of Japanese and incurved blooms. The centre of the display consisted of over seventy enormous blooms of the big white Japanese variety named Queen Mary. Another splendid feature was a huge basket filled about 8ft. high with splendid flowers of the new light yellow Japanese variety, Daily Mail; there were thirty glorious flowers, associated with sprays of scarlet oak. As a contrast, a vase of the tiny yellow pompon, named Baby, with blooms barely half an inch across, was set below the Daily Mail flowers, many of which were 8½ inches across. Other fine Japanese varieties in the display were Mrs. R. Luxford, Kara Dow, the crimson William Vert, H. E. Converse, Mrs. G. W. C. Drexel, and Madame Th. Morel. The best of the singles, presented in large bouquets, were Golden Mensa, Ivor Guest, Miss Kathleen Wells, Caledonia, Eric Wild, Pictor, Feltham Crimson, and Juno. The grouping was bold, and most effective, and ferns were freely used to finish off one of the biggest and finest efforts ever made by this firm.

Mr. Norman Davis, Framfield, Sussex, displayed chrysanthemums finely, as usual, in a large and very artistic display in front of the Royal Box. The graceful outline of the exhibit and the effective and tasteful grouping of the flowers were particularly pleasing. Tall stands of large Japanese and single flowers were raised in front of palms, and in the foreground big vases and bowls of blooms were grouped with crotons, ferns, and small palms. The outstanding single varieties were Mensa, the light yellow Mrs. Loo Thomson, Sussex Yellow, Isobel Felton, and W. Buckingham. The finest Japanese varieties were Col. G. Dixon, a grand new ruby-crimson, Rosamund, Mrs. Drabble, H. E. Converse, Mrs. H. J. Jones, His Majesty, Dandy, D. B. Crane, and Mrs. Will Denis. Of the fine yellow incurved variety named Romance there were superb blooms in big vases. A splendid exhibit that enhanced the Framfield reputation.

A splendid group of chrysanthemums was arranged on table staging in front of the orchestra by Messrs. H. J. Jones, Ryecroft Nursery, Lewisham; the flowers were fine and fresh and presented in bold stands set well apart. The exhibit was, perhaps, a trifle regular and formal in outline as compared with many of Mr. Jones's previous displays, but it was a great effort on the part of those who the previous day had put up a Gold Medal exhibit at the Royal Horticultural Hall. In front of the forty stands of big blooms there were sixty bowls of single and decorative flowers, and in the centre the foreground was extended, and other stands of singles were grouped on the floor with specimen Japanese blooms within an encircling margin of the deep green Helxine Solieroli. The finest Japanese varieties on view were Bob Pulling, Mrs. H. J. Jones, Mrs. R. C. Pulling, F. E. Hutton, new, yellow; Mrs. Kelly, J. Surry, Miss Elsie Davis, Mrs. A. T. Smith, Mrs. Tickle, and Mrs. Howard Kinsey, a new white.

Messrs. Cragg, Harrison, and Cragg, Merivale Nurseries, Heston, Hounslow, arranged their beautiful long-stemmed flowers in large bouquets among neat, dwarf pot plants, with a margin of ferns. The whole exhibit was square in outline, with a wide space between the "borders" and the square-based central pyramid. It must be remembered that the Messrs. Cragg, Harrison, and Cragg grow solely for market, and it was therefore a public-spirited business on their part to stage such a quantity of fine blooms, representing about sixty varieties, five and twenty being their own introductions. We were especially struck by the beauty of their single flowers, notably such varieties as Mensa, Juno, Snow Queen, Loo Thomson, Sandown Radiance, Portia, Max (very fine), Jessica, Orlando, Bronze Pagram, Pink Pagram, Mrs. Garner, Mrs. Tresham Gilby, Irene Cragg, Pink Beauty, Phyllis Bryant, Florrie King, Yellow Star, Bronze Star, Rowena, Elfrida, Elsa, and White Pagram—a splendid selection. The Japanese varieties were not less beautiful, but to these we have frequently made reference.

Messrs. Whitelegg and Page, Chislehurst, put up a fairly large group of single and decorative chrysanthemums in great variety. Messrs. J. Cheal and Sons, Crawley, provided an interesting exhibit of autumn-tinted foliage and flowering shrubs, and also contributed a very clean lot of cactus, single, and decorative dahlias, and again made a feature of their lovely pink, semi-double variety, Crawley Star. Messrs. W. J. Godfrey and Son, Exmouth, had a bright display, and prominent in their group were the large-flowering single varieties Reginald Godfrey, Mollie Godfrey, deep pink; Mrs. Tresham Gilby, Excelsior, Attraction, Miss Margaret Gidley, and Devonshire Lass, the latter a fine soft rose.

Messrs. H. Cannell and Sons, Eynsford, Swanley, filled a large table with a fine collection of clean, bright apples and pears, and the staging of the exhibit was as pleasing as the high quality of the fruit in it. The same firm displayed cut zonal pelargoniums. Messrs. John Peed and Son, West Norwood, contributed a large circular group of chrysanthemums, in which they used single varieties with great freedom and effect.

Messrs. Hobbies, Dereham, provided a very bold display of single chrysanthemums, all pot plants, grouped effectively with stands of collarette dahlias and roses in the foreground. Miss M. Walker, Mrs. Patching, Mrs. Tresham Gilby, Celia, and Florrie King were single chrysanthemums capitally shown by the Dereham firm. Messrs. H. Mash and Son, South Darenth, submitted baskets of excellent apples, and filled a large table with their display.

Begonia Gloire de Loraine was well shown in some quantity by Mr. G. Fisher, gardener to C. Lazenby, Esq., Oakfield, South Eden Park; Mr. S. Mortimer, Farnham, was represented by a bright exhibit of perpetual carnations and winter-flowering stocks, and Messrs. Butler Brothers, Bexley Heath, put up a group of their finely-grown dwarf pot plants of decorative chrysanthemums. Messrs. Stuart Low and Co., Enfield, submitted perpetual carnations in quantity.

MEDALS.

Special Gold Medal, offered by Messrs. Clay and Son, Stratford, for the best non-competitive exhibit in the show.—To Mr. Norman Davis, Framfield, Sussex.

Large Gold.—To Messrs. W. Wells and Co., Merstnam; and to Mr. Norman Davis, Framfield.

Gold.—Messrs. H. J. Jones, Ryecroft, Lewisham; to Messrs. Cragg, Harrison, and Cragg, Merivale, Heston.

Small Gold.—To Messrs. H. Cannell and Sons, Eynsford; to Messrs. J. Peed and Sons, West Norwood.

Silver-gilt.—To Messrs. J. Cheal and Sons, Crawley; to Messrs. H. B. May and Sons, Edmonton; to Messrs. Butler Brothers, Bexley Heath; to Messrs. W. J. Godfrey and Son, Exmouth; to Messrs. Stuart Low and Co., Enfield.

Large Silver.—To Mr. G. Fisher, South Eden Park; to Mr. S. Mortimer, Farnham; to Messrs. H. Mash and Son, South Darenth.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of THE GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in THE GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

THE SCARLET OAK.—T. B. H., Buckinghamshire: My employer, who has been staying in London for a short time, has been much impressed with the value of the foliage of the scarlet oak for use in floral arrangements of a bold character. He has brought some growths home with him, and is desirous of growing this oak for furnishing similar sprays of foliage. These growths are more robust than those we are able to cut from trees in the grounds, and I shall be obliged by your advising as to the proper course of procedure in the production of shoots of a similar character.—The best course to obtain a supply of strong growths is to plant half-a-dozen or so of dwarf trees in a convenient position, in well-prepared soil, and, in the course of the winter, prune them hard back. In subsequent winters prune such of the shoots that have not been used for decorations back to within one or two buds of the base.

UNHEALTHY VIOLETS.—T. S., Bury: We grow violets under glass rather largely, and are usually very successful. This year they are not quite so satisfactory as I could wish, and some appear to be damping off. Can you help me to prevent further injury to them?—The plants that you have sent us suggest a close atmosphere, owing to insufficient ventilation. We suggest that you admit air more freely to the frames, especially during periods of bright, dry weather, and carefully dust the surface of the beds between the rows of plants with slaked lime.

COLLARETTE DAHLIAS. — M. E. A., Cheriton: I shall be greatly obliged if you will publish as complete a list as possible of collarette dahlias, with brief descriptions. I have made notes of many varieties this season, but I should like to know whether there are others of similar colouring before I place orders for plants for next spring.—The following is as complete a list of collarette dahlias as we can compile from the material at hand: Antwerpia, crimson scarlet, yellow collar.; Ami Cochet, reddish orange with straw collar.; Albert Maumene, mauve, white collar.; Balmoral, puce colour, white collar; Buckingham, blood-red, white collar.; Carl Bechstadt, scarlet and yellow; Cloch, lavender, yellow collar.; Countess Douzon, white ground, white collar.; Comtesse Icy Hardegg, maroon, white collar.; Crimson Queen, purple crimson, white collar.; Diadem, rose colour, white collar.; Exposition de Lyon, rosy cerise, white collar.; Frogmore, yellow and vermilion, collar. yellow; Gallia, cream with rose, creamy collar; General de Sonis, crimson, yellow collar.; Goldstern, yellow, yellow collar.; Holyrood, rich ruby colour, yellow collar.; Henri Farman, vermilion, straw collar.; Inchcolm, white; Inchmarnock, salmon scarlet, yellow collar.; Hon. Vicary Gibbs, crimson scarlet, straw collar.; Joseph Jougon, ruby colour, cream collar.; Le Congo Belge, maroon, light collar.; Lowestoft, clear yellow self; Leitstern, velvety maroon, white collar.; Meteor, crimson, primrose collar; Madame J. Buyssens, crimson, straw collar.; Madame Empain, brown, sulphur collar.; Madame Gygax, yellow, primrose collar.; Madame R. Ferange, pink, straw collar.; Madame E. Poirier, violet, white collar.; Maurice Rivoire, crimson, white collar.; Negro, maroon, white collar.; Princess Charlotte, crimson, straw collar.; Prince John, crimson, white collar.; Princess Louise, crimson, white collar.; Prince of Orange, orange and yellow; Prince de Venosa, crimson, white

CONTENTS.

Culture of the Apple, Apricot, Damson, Blackberry, Bullace, Cherry, Crab, Cobnut, Cranberry, Currant, Fig, Gooseberry, Grape, Medlar, Loganberry, Plum, Pear, Peach, Quince, Mulberry, Nectarine, Raspberry, Strawberry, Wineberry, Etc.

ALMOST READY. A NEW GARDEN BOOK OF GREAT IMPORTANCE.

FRUIT AND ITS . . . CULTIVATION

By T. W. SANDERS, F.L.S., F.R.H.S.

Send for Illustrated Prospectus.

This up-to-date work truly may be termed an Encyclopædia of the Whole Art of Growing Fruit with Success. No matter whether the problem is to grow fruit in the Garden, Orchard or Plantation, herein will be found sound and practical information. Although written in the interests of fruit growers of all degrees, special attention is devoted to the requirements of Amateurs and those who desire as Small-holders to grow fruit for profit on their holdings. A splendid guide to a profitable pursuit.

PRICE SIX SHILLINGS NET (By Post, 6s. 4d.)

Crown 8vo, Cloth. 352 Pages. 64 Plates. 145 Plans and Diagrams.

CONTENTS.

Varieties, Propagation, Planting, Pruning, Training, Manuring, Storage, Enemies, Diseases, Remedies, Pollination, Protection, Orchards, Plantations, Packing, Spraying, Tables for Fruit Growers, Etc.

collar.; Purity, white self; Queen Anne, scarlet, straw yellow collar.; Queen Bess, scarlet, yellow collar.; Queen Mary, rose, blush collar.; Rheinkvone, maroon, white collar.; Souv. de R. Bernedean, white and crimson, cream collar.; The Czar, deep rose, white collar.; Tusca, crimson, and rose, and white; Victoria, rich lake, straw collar.; Vilmorin-Andrieux, purple, white collar.; and Windsor, light yellow, straw yellow collar.

MARKET CERTIFICATES FOR CHRYSANTHEMUMS.—J. S., Exeter: I see by your columns that the Floral Committee of the National Chrysanthemum Society now awards Market Certificates to deserving varieties. Will you kindly tell me the basis of judgment followed in these cases?—Your letter arrived just as we were going to press, and not having a copy of the list of points which the N.C.S. has drawn up for the purpose of awarding market certificates, we must ask you to kindly refer to our next issue, when we hope to supply the information.

BERBERIS FOR THE ROCK GARDEN.—M. E. G., Chepstow: You will much oblige me by stating which species of berberis you consider the best for a comparatively small rock garden.—All things considered, we think the new Berberis Wilsonæ is the best species for a rock garden, as it is of modest growth, berries freely, and is very pretty.

DECAY OF CALADIUM CORMS.—W. S. H., Leeds: Each year I lose a considerable proportion of my caladium corms, although I take the greatest possible care of them. To prevent them being injured by an excess of moisture I turn them out of the pots in November, and, after shaking away the soil, I put them in flower pots, and cover with dry silver sand. Am I right in doing this?—It is a grave mistake to attempt to keep the corms of caladiums in dry sand, in accordance with your practice. The best course is to allow the corms to remain in the pots in which the plants were grown the previous season. If you do this and keep the soil dry you have no further losses.

NAMES OF PLANTS.

G. F., Yorkshire.—1, Gaultheria Shallon; 2, Hippohæ rhamnoides.

S. H., Sussex.—1, Dendrobium Phalænopsis; 2, Cypripedium Harefield Hall; 3, Epidendrum vitellinum majus; 4, a good form of Cattleya labiata.

F. K.—1, Begonia Rochfordi; 2, B. Mrs. Heal; 3, one of the perpetual-flowering carnations, but the bloom was undersized and so much shrivelled that it was impossible to recognise it .

S., Norwich.—The specimens sent were too small to admit of identification. If you will send larger specimens with flowers, we will do our best to assist you.

W. B., Leicester.—1, Cotoneaster buxifolia; 2, Pyracantha Lælandi, more generally known as Cratægus pyracantha Lælandi; 3, Azara microphylla; 4, Elæagnus pungens aureo maculatus; 5, Pittosporum Tobira variegatum; 6, Griselinia littoralis.

NAMES OF FRUIT.

R. M., Kent.—1, Lord Derby; 2, Flower of Kent.

B., Hunts.—Your grape is Lady Downes Seedling.

F. B., Sussex.—1, Easter Beurre; 2, Glou Morceau; 3, Fruit so deformed as to be unrecognisable.

F. L., Shropshire.—1, Durondeau; 2, Doyenne du Comice; 3, Winter Nelis; 4, President Barabe.

W. W.—1, Cox's Orange Pippin; 2, Bauman's Red Winter Reinette; 3, Cornish Aromatic; 4, Allington Pippin.

H. Smith.—1, Lord Derby; 2, Bramley's Seedling; 3, Hambledon Deux Ans; 3, Newton Wonder; 4, Annie Elizabeth; 5, The Queen; 6, Ecklinville.

OBITUARY.

MR. J. CHANNON.

For over forty years Mr. J. Channon was gardener to the Peacock family at Grosvenor Lodge, London Road, Croydon, and not long since he was the recipient of a handsome bequest from a late member of the family. This he did not live long to enjoy, as he passed away somewhat suddenly a few days ago at the age of 66 years. Mr. Channon was a well known member of the Croydon Gardeners' Society, and this body sent beautiful flowers to the funeral on Tuesday last. He was a capable gardener, and a most interesting personality, and for a number of years he acted as local secretary for the Royal Gardeners' Orphan Fund.

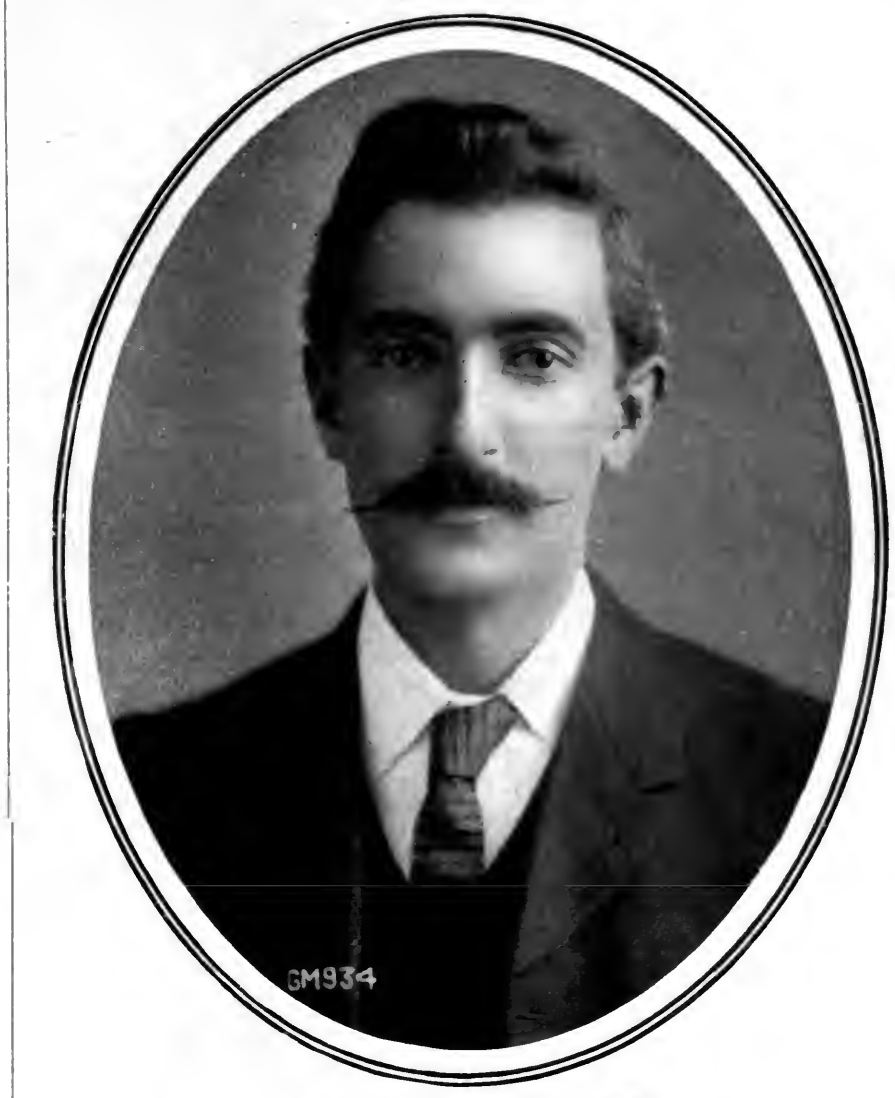
THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

A Great Naturalist.

The death of Dr. A .R. Wallace, at the ripe age of 91, has snapped the last link of the chain that connected present-day workers in the vast field of natural history with the great naturalists of the Victorian era, and removed from our midst one who has rendered services of such commanding importance that they will not be readily forgotten by those who are engaged in the investigations of the many interesting questions associated with animal and plant life. He was best known in scientific circles as the co-discoverer with the late Charles Darwin of the principle of natural selection as the chief agent in the evolution of species, and by those possessing a taste for the literature of natural history he will long be remembered for his highly entertaining and important works relating to this interesting science. He, however, did not limit his literary labours to works of travel, or to works on philosophical and systematic natural history, but wrote much in the course of his long life on subjects outside the realms of science, but having, as he believed, a distinct bearing on the welfare of the country and the health and happiness of the several classes of the community.



MR. J. S. CHISHOLM.

Born at Usk, in Monmouthshire, on January 8, 1823, he lived with his parents until 1836, when he took up his residence with an elder brother, who was a land surveyor and architect, and remained with him twelve years. During this period he had opportunities for travelling through several parts of England, and obtained a considerable knowledge of agriculture, and became well acquainted with the economic and social conditions of workers on the land, in whom, later in life, he evinced much interest. Before he had passed out of his teens he turned his attention to the study of natural history, and devoted the whole of his spare time to the collecting, drying, and mounting of native plants, and reading books of travel. When, in 1844-5, he was engaged as an English master at a middle-class school in Leicester, Dr. Wallace became acquainted with the late Mr. W. H. Bates, who also attained a high position as a naturalist. A few years later, when the desire to visit tropical regions became irresistible, Dr. Wallace suggested to his friends a joint expedition to the Amazons for the purpose of collecting natural history specimens and gathering facts, as stated in a letter to Mr. Bates, "towards solving the problem of the origin of species," which had been the subject of frequent discussions between the two friends. The joint expedition was arranged, and early in 1848 they left this country, and reached the mouth of the Amazon on April 20 of that year, and at once commenced the explorations that were destined to make both famous. They continued their work of exploration in association until early in 1850, when, by another route, Mr. Bates continued his investigations of the flora and fauna of the Amazon, and Dr. Wallace turned his attention to the exploration of the Rio Negro and the higher reaches of the Orinoco. The adventures of the latter during the next two years, and his observations on the natural history, and the tribes inhabiting the Amazon valley, are recorded in a most entertaining manner in his "Narrative of Travels on the Amazon and Rio Negro," which contains many facts relating to the causes and modes of transformation of species. In 1852 Dr. Wallace returned to England, but the homeward journey was adventurous and unfortunate, for the vessel in which he sailed caught fire and was destroyed. As the result thereof he lost the large and valuable collection of specimens he brought with him, and had to spend ten days in an open boat. A portion of the collection he had made was fortunately sent home previous to his return, and reached this country in safety. Dr. Wallace remained in England two years, and throughout this period he was busily engaged in the preparation and publication of the work above mentioned, and to the disposal of the specimens that had reached their destination without a mishap. Neither the difficulties he had to surmount in the course of his explorations in the valley of the Amazon, or the dangers and losses experienced on his return voyage, abated the interest of Dr. Wallace in tropical regions; and early in the summer of 1854 he started for the Malay Archipelago, so rich in plant life. Here he evidently found a happy hunting-ground, for he remained eight years, and during this period he travelled about 14,000 miles, visiting Borneo, Celebes, Java, New Guinea, Sumatra, and other regions—some more than once. He achieved so high a degree of success during his explorations that he was able to bring back with him in 1862 upwards of 125,000 specimens, illustrative of the fauna and flora of the places visited. The examination and classification of this immense collection must have been a heavy task, and we have a proof that it was so in the fact that not until 1869 was he able to see his second great work, "The Malay Archipelago," through the press. As will have been seen from the quotation from the letter written to Mr. Bates, Dr. Wallace evinced from a quite early period in his life a deep interest in the problem involved in the origin of species. To mention this is a point of much importance, as evidence of the trait in his character which obtained for him the esteem of the scientists, not alone of this country, but of the whole

world. Dr. Wallace was first introduced to Mr. Charles Darwin in 1854, but nothing appears to have then been said with reference to the matter that had for some time been engaging a considerable share of the attention and thought of both. As known for many years past, Mr. Darwin had in 1842 written an outline of the law of natural selection, and in an extended form it had been read by Sir Joseph Hooker and Sir Charles Lyell in 1844, but it does not appear to have been mentioned to anyone else. In a paper published in the "Annals and Magazine of Natural History" for September, 1855, "On the Law that has Regulated the Introduction of New Species," Dr. Wallace stated that he had arrived at the conclusion that "every species had come into existence coincident both in space and time with a pre-existing closely allied species"; and Mr. Darwin, in writing to Dr. Wallace, stated that he was in general agreement with his views as therein expressed. In February, 1858, Dr. Wallace, who was then at Ternate, wrote an essay "On the Tendency of Varieties to Depart Indefinitely from the Original Type," and sent the manuscript to Mr. Darwin, who was perturbed by the close similarity of the views expressed therein to his own. The question of publishing this theory was beset with some difficulty, because both were anxious not to obtain an undue advantage; but it was overcome by Sir Joseph Hooker and Sir Charles Lyell arranging to communicate to the Linnean Society, on July 1, 1858, a joint paper by Mr. Darwin and Dr. Wallace. This paper, as well known, created wide-spread interest in scientific circles, and resulted in a lifelong friendship between these two great naturalists.

Mr. J. S. Chisholm, the chief lecturer in horticulture at the Edinburgh and East of Scotland College of Agriculture, and adviser in horticulture to the twelve counties in the college area, is a native of Berwickshire, and was born at Houndwood, where he also commenced his horticultural career. After working for several years in private gardens, he went to Edinburgh to take advantage of the three years' course in the Royal Botanic Gardens. Here he was employed in various departments, and took advantage of his opportunities for study. He sat for several examinations in the various subjects which underlie horticultural practice, and secured a First-class Diploma. In addition to this he studied extra subjects, and in 1904 obtained the medal for horticulture at the Heriot-Watt College. Shortly after this success he was appointed lecturer in horticulture to the Northumberland County Council, with charge of the horticultural and forestry departments at the Experimental Station, Cockle Park, Morpeth. Here Mr. Chisholm remained for eight years, and during that period he planned and carried into effect an excellent scheme of gardening instruction and nature study throughout the county. A year ago Mr. Chisholm went to Edinburgh, and in May last received his present appointment. Mr. Chisholm is an easy speaker, and we have on many occasions heard him lecture and give demonstrations. He has had an excellent training for the position he occupies, and has already added to his reputation at Edinburgh as an instructor who interests as well as teaches.

Dahlias at Barry in August and November.—Barry Summer Show was held on August 4, and the Autumn Show on November 5, and on both occasions a very fine display of dahlias was made by Mr. A. Cobb, gardener to R. Cory, Esq., Duffryn, Cardiff. It is not too much to say that at the November Show the dahlias were the chief attraction, and as they represented practically every florist's section of the dahlia, the interest taken in this flower was very keen. Object lessons of this kind demonstrate the worth of dahlias, their great variety of form and colour, and their lengthened season of flowering.

The National Chrysanthemum Society's Annual Dinner will take place on Friday, November 28, at 6.45 p.m., in the Royal Venetian Chamber, Holborn Restaurant London, W.C., when the president, Sir Albert Rollit, D.C.L., LL.D., will preside. The various trophies, cups, medals, etc., will be presented during the evening. Mr. T. Bennett Griffin has charge of the musical arrangements. Tickets, 5s. each, exclusive of wine, may be obtained from the secretary, Mr. Richard A. Witty, 72, Savernake Road, Gospel Oak, N.W.

Value of Grading and Packing Apples. — Many Kentish fruitgrowers are adopting Australian methods in dealing with dessert apples. After being graded, each fruit is wrapped in tissue paper and packed in boxes of convenient size, with the result that a box of eighteen first-class apples sell for 4s.—or about 5d. per lb.

Eradication of Bracken in Scotland.—Efforts are being made in various parts of the country to eradicate bracken from what would otherwise be useful land. Colonel Ferguson-Buchanan has for many years been improving his Auchentorlie estate, and in an address given at the West of Scotland Agricultural College recently, he told how, by the use of a thistle cutter, making successional cuttings during the year, and never allowing bracken to ripen its spores, he had raised the value of 700 acres of land from 4s. to 6s. per acre, at a cost of £430, spread over eight years. Harrowing and burning he considered useless as a means of eradicating the bracken, but frequent cuttings, commencing when the fronds are three inches high, is the best method.

Horticultural Club.—A house dinner of the Horticultural Club will take place at the Hotel Windsor, Victoria Street, Westminster, on Tuesday next (the 18th inst.), when Mr. Reginald Farrer will give a lecture, entitled "Not about Switzerland." The dinner will, as usual, commence at 6.30 p.m.

Liverpool Parks and Gardens.—At a recent meeting of the Parks and Gardens Committee of the Liverpool Corporation some very interesting particulars were given respecting the recreation spaces under its control. These places number eighty-one, and comprise nine parks, thirty-two recreation grounds, and forty gardens—in all about 1,100 acres, or over one-fifteenth of the present area of the city. Further additions to the extent of over one hundred and fifty acres are to be acquired. Extensive accommodation is given for football, cricket, and lawn tennis, over four hundred clubs being provided with grounds for these games, in addition to provision made for girls' rounders and hockey clubs. Children's gymnasia are erected in twenty-five of the recreation grounds, and nearly 20,000 school children held picnics in the parks during the past summer. Thirty-two bowling greens can scarcely accommodate the ardent trundlers who patronise them; while on four of the park lakes ninety-five boats are provided, the receipts from which amounted to £1,152 this season. The year's receipts from boating, bowling greens, football and cricket plots, and other games, were £3,400. The net cost of the parks amounted to £28,000 yearly, and nearly £20,000 was paid in salaries and wages. The Chief Superintendent and Curator of Parks and Gardens, Mr. James J. Guttridge (an old Kewite), is a zealous lover of flowers, and continuous floral displays are provided at Sefton Park, Stanley Park, and the Botanic Gardens. During the greater part of the year the flower beds in the parks and gardens are brilliant with bloom, over 250,000 bedding plants being required to fill them. The annual chrysanthemum shows are now open at Sefton, Stanley, Newsham, and Calderstones Parks, and for the next five or six weeks will afford much pleasure to the crowds of visitors who go to see them.

A Hard Winter Predicted.—Quite a number of weatherwise people are predicting a very severe winter. There has been a succession of mild winters, and now a severe one is due to restore the balance. Sir Oliver Lodge forecasts hard weather, and also suggests that it will be clear as well as cold. Horticulturists generally will not mind a severe winter, provided the weather is clear and fairly dry, and, also, provided the winter does not last into springtime. The plague of slugs and other pests experienced this year is due largely to mild, moist winters, but the ranks of the enemies would be severely thinned by a hard winter. Anyhow, it is as well to be prepared for keen frosts, even if they do not come.

The English Sugar Beet Harvest.—Very considerable progress is being made in the beet sugar industry in this country, and Norfolk is the chief centre of operations. A large factory has been built at Cantley, between Norwich and Yarmouth. About 4,500 acres are under beet this season, and harvesting is in full swing. The estimated yield is an average of 14 tons per acre, or 63,000 tons. Expert cultivators secure from 15 to 20 tons of sugar beets per acre, and such crops are considered to pay well. A number of Dutch workmen have been engaged this season, as last, to deal with the roots as brought in, and prepare them for manufacture, but as the local workmen, numbering about 400, get used to the work, imported labour will not be necessary.

Chrysanthemum Conference at Essex Hall.—A chrysanthemum exhibition and conference will be held at Essex Hall, Essex Street, Strand, W.C., on December 10. The exhibition will be opened at one o'clock, the Floral Committee will meet at 3 p.m., and the conference will commence at 7 p.m., —Sir Albert Rollit, D.C.L., LL.D., presiding. Mr. Norman Davis will read a paper entitled "The Evolution and Development of Outdoor Chrysanthemums." This will be followed by a paper by Mr. Thomas Bevan, on "Chrysanthemums for Outdoor Garden Decoration," illustrated by limelight views. The two papers will then be open for discussion. A very interesting debate is anticipated, and it is hoped that members will be present in large numbers. Members of affiliated societies are particularly invited to be present.

Export of English Apples to Cape Town.—Consignments of apples from Kent are being sent to Cape Town, where they meet with a ready sale at remunerative rates. They are packed in boxes holding about one bushel of fruit.

BIRMINGHAM CHRYSANTHEMUM AND FRUIT SHOW.

Bingley Hall, Birmingham, on November 11, 12, and 13, was well filled with beautiful flowers, plants, and other horticultural products, the occasion being the show of the Birmingham and Midland Counties' Horticultural Society. There were those present who could look back upon bygone years, and could remember shows that were more extensive and of higher quality than that of this year, but, for our part, we were well pleased to note that, on the whole, things were about as good as usual, whilst there were in minor details of arrangement undoubted improvements that added to the enjoyment of visitors.

FIRST PRIZE EXHIBIT OF TWELVE C HRYSANTHEMUMS, WITH DECORATIVE FOLIAGE,
At Birmingham Show, exhibited by Mr. J. R. Tooley, gardener to Hugh Andrews, Esq., Toddington Manor, Winchcombe.

PLANTS.

Year by year the popularity of the trained specimen plants of chrysanthemums seems to wane, and in the half-dozen classes provided there was practically no competition, Mr. Alfred Cryer, gardener to J. A. Kenrick, Esq., Berrow Court, Edgbaston, being awarded first prizes for six large-flowered Japanese, and for three plants, and a single specimen. The same exhibitor had the best three plants of single-flowered varieties, second prize in this class going to Mr. Rayner Bullock, gardener to T. W. Piggott, Esq., The Lions, Moseley. Mr. J. S. Higley, gardener to Godfrey Nettlefold, Esq., South Bank, Edgbaston, taking third prize.

In the group classes there was again but little competition, the principal group occupying 16ft. by 10ft., having only one entry, which came from Mr. Alfred Cryer. It was, however, a magnificent exhibit, in which grand plants were used with great skill and taste. A central mound at the back rose to a great height, and contained many immense blooms of the best varieties, and on either side of the foreground rose pyramids of choice incurved and Japanese varieties. Cut blooms of good quality were used to finish off the front, together with small crotons, ferns, and grasses. Mr. Cryer was also alone in the group of decorative chrysanthemums, occupying 12ft. by 8ft. Single varieties of bright colours were freely used, with small-flowered Japanese, the whole being tastefully grouped to present a very pleasing effect.

In the smaller group, combining large-flowered and decorative varieties, there were two entries, the first prize being secured by Mr. F. W. Love, gardener to the Studley Horticultural College, Studley, Warwickshire. There were some nicely grown Japanese flowers, but the greater portion of the group was made up of singles and decorative flowers, and of these there were decidedly too many for the 12ft. by 8ft. space. Mr. L. Fewkes, gardener to H. Green, Esq., Gravelly Hill, Birmingham, who was placed second, had a very good lot of large-flowered Japanese, which, on the whole, were of good quality, and were so arranged that each flower stood well out to show its merits. There was some expression of opinion that this group more correctly fulfilled the conditions of the schedule than did the other.

CUT FLOWERS.

A most attractive class was that for a table of cut chrysanthemums, Japanese and incurved, with ferns and foliage plants, the space allotted each exhibit being 18ft. by 5ft. There were three strong entries, and the leading position was well taken by Mr. Norman Davis, Framfield Nurseries, Sussex. The background was given up to huge blooms of beautiful white, yellow, and crimson Japanese varieties, whilst in front there were grand stands of perfectly-formed incurves, and the table base had other large flowers dispersed among pteris and nephrolepis, with trailing selaginellas. This exhibit secured a silver challenge shield in addition to the cash prize of £8. Mr. H. Woolman, Shirley, Birmingham, came a good second with tall stands of big blooms, and smaller vases of incurves, the decorations being crotons, ferns, and small palms. Mr. John Sherratt, Burton-on-Trent, received third prize, his exhibit lacking something in boldness of arrangement.

The class for six vases of Japanese varieties, each containing three blooms, all distinct varieties, had three entries, the first prize being awarded to Mr. E. J. Brooks, gardener to Lieut.-Colonel Beech, Brandon Hall, Coventry. The Hon. Mrs. Lopes, Miss A. E. Roope, Lady Talbot, and F. S. Vallis were all good yellows; Queen Mary and William Turner, whites; and William Mease, Frances Row, and C. A. Broomhead were good bronze and red varieties, all well-formed, fresh, and large blooms. Mr. H. Woolman, Shirley, took second prize with somewhat smaller, but still very nice flowers, which included Thomas Lunt, Mrs. T. Stevenson, Reg. Vallis, and other good varieties. Third prize went to Mr. J. R. Tooley, gardener to Hugh Andrews, Esq., Toddington Manor, Winchcombe. Mr. Brooks was again to the fore with three vases in three distinct varieties, three blooms of each. John Peed, a pale lilac mauve, F. S. Vallis, of wonderful size, and the massive white William Turner were the varieties used. Mr. H. Woolman again followed for second place, his varieties being Miss A. E. Roope, Mrs. H. J. Jones (both yellows), and Mrs. Gilbert Drabble, the latter being beautifully-developed blooms. Mr. W. H. Westbury, gardener to J. H. Wheatley, Esq., Berkswell Hall, Coventry, received third prize.

A class of special interest was that for twelve Japanese blooms placed on a table with small foliage plants and ferns as a setting. There were five capital entries, and some splendid flowers were staged. Mr. J. R. Tooley, gardener to Hugh Andrews, Esq., Toddington Manor, Winchcombe, was first-prize winner, his flowers being large, beautiful, fresh, and just fully developed, whilst they were well arranged against a background of black velvet, with small crotons

and coleus for embellishment. A gigantic bloom of F. S. Vallis was outstanding, but W. Rawlings, Pockett's Crimson, Bessie Godfrey, and Bob Pulling were also splendid flowers. Mr. Rayner Bullock was a good second, although one or two of his flowers were a trifle out of form. Third prize went to Mr. A. W. Young, gardener to Mrs. R. Peyton, Edgbaston, who had an even and pretty lot of flowers that did not equal the foregoing in size. Mr. E. Avery, gardener to J. B. Brooks, Esq., Finstall Park, Bromsgrove, was placed fourth, and a fifth prize was awarded to Mr. T. W. Davis, gardener to H. F. Keep, Esq., The Grange, Edgbaston.

Incurves did not make a big show, but some nice flowers were staged in the class for four vases containing twelve blooms distinct. Mr. T. W. Davis, gardener to H. F. Keep, Esq., The Grange, Edgbaston, led the way, showing a refined bloom of C. H. Curtis, a good Romance, and also Clara Wells, with other well-known varieties. Mr. Rayner Bullock was winner of second prize, his Madame E. Roger, Buttercup, and Fred. Palmer being neat, shapely flowers. Third prize was awarded Mr. Harry Hall, Halesowen.

Single vases of three blooms each were shown in separate classes to colour, the best vase of pink coming from Mr. Westbury, Reg. Vallis being the variety. Mr. Woolman's vase of His Majesty secured first prize for a crimson variety, and the same exhibitor's Miss A. E. Roope won first prize as the best yellow of five entries. Mr. Brooks came to the fore again for a white variety, showing William Turner in superb form.

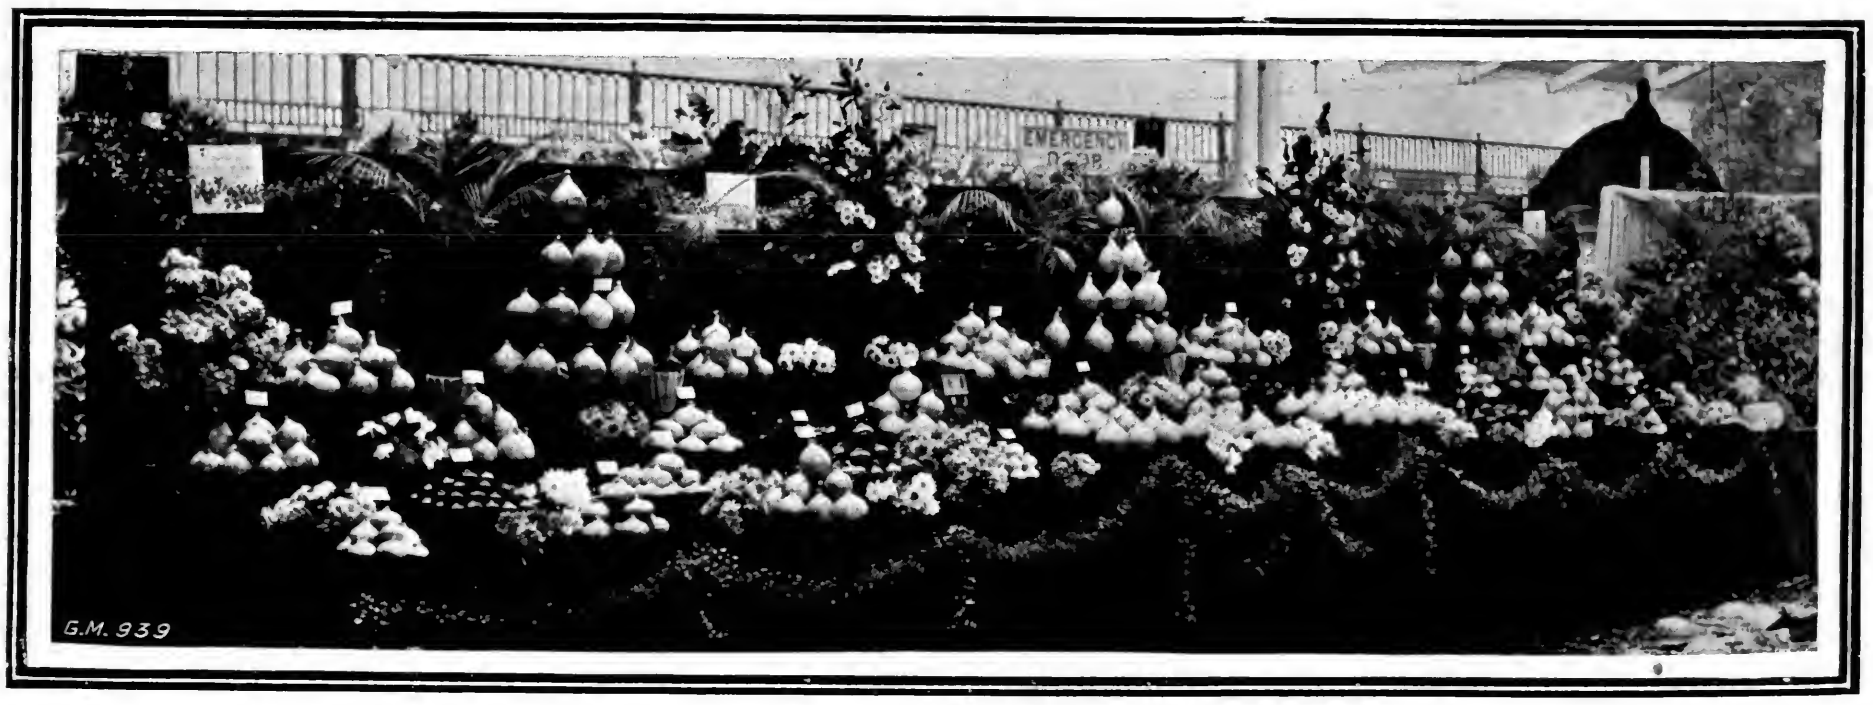
A table of cut single chrysanthemums, 8ft. by 4ft., arranged with foliage, brought first prize to Mr. Wm. Newton, gardener to Major Everett, J.P., Knowle Hall, Knowle. Yellow and bronze varieties predominated, but a few deep crimsons and brighter red and pink varieties gave the touch of variety required, and the effect of the whole was good. Mr. Rayner Bullock received second prize with a somewhat thin and flat arrangement, in which white and delicate shades largely predominated. Some of the flowers were very large, and bespoke good culture. Third prize was awarded Mr. E. Bostock, gardener to E. Martineau, Esq., Edgbaston. For four vases of single chrysanthemums in sprays, Mr. M. V. Wall, gardener to Jas. Booth, Esq., Ardencote, Claverdon, secured first prize, his varieties being J. H. Greswold Williams, yellow; Ceddie Mason, crimson; Coronation, pink; and Countess of Egmont, bronze. All were fine large flowers, and clear in colour. Mr. A. H. Hickman, Eagle and Spur, Cookley, took second prize, and he also had first prize for six vases of decorative varieties, each vase containing six sprays. Mr. J. Valet, a pure white, was very good, and somewhat larger than Felton's Favourite.

MISCELLANEOUS PLANTS AND FLOWERS.

The exhibits of primulas, cyclamens, and other winter-flowering plants seem to diminish every year, but one thing that still comes along in strong force is Begonia Gloire de Lorraine. In a class for twelve pots, Mr. A. Cryer scored a success with a dozen capital specimens, well flowered from base to summit; Mr. J. S. Higley, gardener to L. Spiers, Esq., Edgbaston, received second prize; and Mr. J. Farmer was third in a strong class. Mr. Cryer secured the premier award for a dozen cyclamen, and Mr. Higley led the way for Primula obconica.

TABLE DECORATIONS.

There was but one class for table decorations, but it brought upwards of two dozen entries, and it can only in fairness be said that every table was a credit to the competitor. The fortunate winner of first prize was Mrs. Batchelor, Hampton-in-Arden, who used yellow and bronze single chrysanthemums with Adiantum gracillimum, and trails of small-leaved ampelopsis. There was just enough on the table to make a decoration, but no overpowering display. Second prize was given to Miss A. S. Herbert, Acock's Green, who used very pretty bronze-coloured flowers with narrow croton leaves. Mr. T. Batchelor, Hampton-in-Arden, was placed third with a pretty yellow and crimson combination.



A NOTEWORTHY DISPLAY OF WELL-GROWN ONIONS,
Exhibited at Birmingham Chrysanthemum and Fruit Show by Mr. E. R. Janes, gardener to the Right Hon. Lord North, Wroxton Abbey, Banbury.

FRUIT.

It has for many years been customary to find a collection of fruit exhibits at Birmingham Show that would compare with any show in the country, and it is no exaggeration to say that this section this year was of tip-top quality, and without a doubt made the most important feature of the show apart from the chrysanthemums themselves. The opening class in the section was for a table of British-grown fruit occupying 10ft. by 5ft. There were three entries, and, as the judges remarked at the luncheon, they provided a most difficult task when it came to awarding the prizes. Mr. J. R. Tooley, Winchcombe, deserve congratulation on receiving first prize for his collection, which included Muscat of Alexandria, Gros Colmar, Golden Queen, and Alicante grapes, some dishes of beautiful apples, such as King of the Pippins, Rival, Cox's Pomona, Royal Jubilee, and others, together with Beurre Alexandre Lucas, Beurre Diel, Charles Ernest, and Beurre Clairgeau pears, and a good dish of medlars. The table was nicely decorated with crotons and trails of ampelopsis. Mr. G. Mullins, gardener to Lady Henry Somerset, Eastnor Castle, Ledbury, was a very close second with some splendid fruit, just perhaps a trifle behind the winner in condition of grapes, although they were by no means to be despised; while the apples, such as Adam's Pearmain, Mère de Ménage, Queen, and Gascoyne's Seedling, were fine samples, as also were Pitmaston Duchess pears and Countess Melons. Mr. J. H. Goodacre, gardener to the Right Hon. Earl of Harrington, Elvaston Castle, Derby, was third; and, as might be expected from this veteran exhibitor, the fruit shown was of a very high order of merit.

Another most interesting class was that for a collection of British-grown hardy fruit on a table 12ft. by 8ft., and here again there were three entries, each of which was deserving of high praise. The successful exhibitor was Mr. C. Crooks, gardener to H. Mitchell, Esq., Impney, Droitwich, who had a splendid lot of dessert and culinary apples and pears, besides such things as medlars, and fruits of Passiflora edulis. The pears were grand, the fruit of Beurre Diel, Conference, Doyenne du Comice, and Beurre Bacheleuse being perfect in form and beautifully finished. The apples included superb examples of Lord Hindlip, Belle de Pontoise, Wealthy, Crimson Queen, and a number of other excellent varieties, every dish being of remarkably good quality. The second prize was awarded Mr. Hy. Cotton, gardener to Lord Biddulph, Ledbury Park, Ledbury, who was strong in apples, but lost points with his pears. He had capital medlars, walnuts, and Kentish cobs, as well as chestnuts; and, taken all round, the exhibit was very fine. Third prize was given to Mr. C. W. Powell, Warham, Hereford, and even this lot would have carried the exhibitor to victory in many shows.

Grapes were well shown, the first prize for six bunches going to Mr. J. R. Tooley, Winchcombe, who put up heavy clusters of Alicante, Gros Colmar, and others; second prize went to Mr. J. H. Goodacre, who had Gros Maroc in good form, with Muscat of Alexandria and Alicante; third prize went to Mr. G. Mullins, Ledbury. The best three bunches of black grapes were shown by Mr. Mullins, Gros Maroc being the variety shown; second prize in this class going to three bunches of Alicante shown by Mr. J. R. Tooley, third prize being awarded Mr. J. H. Goodacre. Mr. J. R. Tooley led for three bunches of white grapes, showing Muscat of Alexandria in capital form; he was followed by Mr. T. Bannerman, gardener to Lord Bagot, Blithfield Hall, Rugeley; Mr. Sheppard, gardener to Chas. Winn, Esq., Selly Park, coming third. The best two bunches of black grapes came from Mr. J. S. Higley, gardener to Godfrey Nettlefold, Esq., South Bank, Edgbaston; second prize going to A. G. Buller, Esq., Kingfield, King's Heath, Birmingham; Mr. A. Cryer coming in for third prize—the stipulation in this class being that the exhibitor resides within four miles of the centre of Birmingham.

(Continued on page 871.)

WINTER TREATMENT OF PERPETUAL FLOWERING CARNATIONS.

The correct management of perpetual-flowering carnations during the winter months is an important matter. The first essential item is a suitable house. A span-roof house facing due south is the best, as it obtains the maximum amount of sun and light during the dull days of the year.

Carnations require a fairly cool and buoyant atmosphere, consequently ventilating and heating must receive special attention. Whenever possible, leave the ventilators at the top of the house open a little way all night, provided this can be done without lowering the temperature too much. It is a good plan to use sufficient heat to maintain a minimum temperature of 80 degrees at night, but the pipes in the carnation house must not become really hot. In big houses a large number of pipes kept comfortably warm are greatly to be preferred to half the quantity of piping overheated. The latter will encourage red spider and other evils. A suitable day temperature for the carnation-house is from 55 to 60 degrees, according to the conditions prevailing outside. On a bright, mild day admit air freely, and gradually lower the ventilators as the natural warmth declines. At the same time begin to raise the warmth in the hot-water pipes.

Admit air very judiciously on damp, foggy days, as such weather facilitates the development of rust. Under such conditions it is necessary to employ sufficient fire heat to counteract the moisture in the atmosphere, and so keep the air of the house light and buoyant. Only by a combination of air and artificial heat can ideal atmospheric conditions be maintained in winter.

Watering requires great care. Allow the soil to become moderately dry, and then afford sufficient water to moisten it all through. Do not allow the plants to remain in a really dry condition, so that they flag at the first outburst of sun, as such irregularities often give a check, and are sometimes the cause of the blooms failing to open properly. It is advisable to give water in the morning, and one must be careful not to spill water about the house.

Feeding must be very judiciously carried out in winter, if at all; experts differ on this matter. Nevertheless, the fact remains that those who apply weak stimulants occasionally obtain larger blooms than those who do not. Occasional light top-dressings of a really good carnation manure will produce fine blooms of good colour, besides building up the growth of the plants, and assist the developing buds to expand. Such feeding is in no way harmful to the constitution of the plant. I have found Bentley's a really excellent carnation fertiliser, if used in the form of a very light top-dressing in winter; but after the turn of the year the plants demand additional nourishment with their increasing growth. Clear soot-water forms a good change, and may be used at almost all seasons.

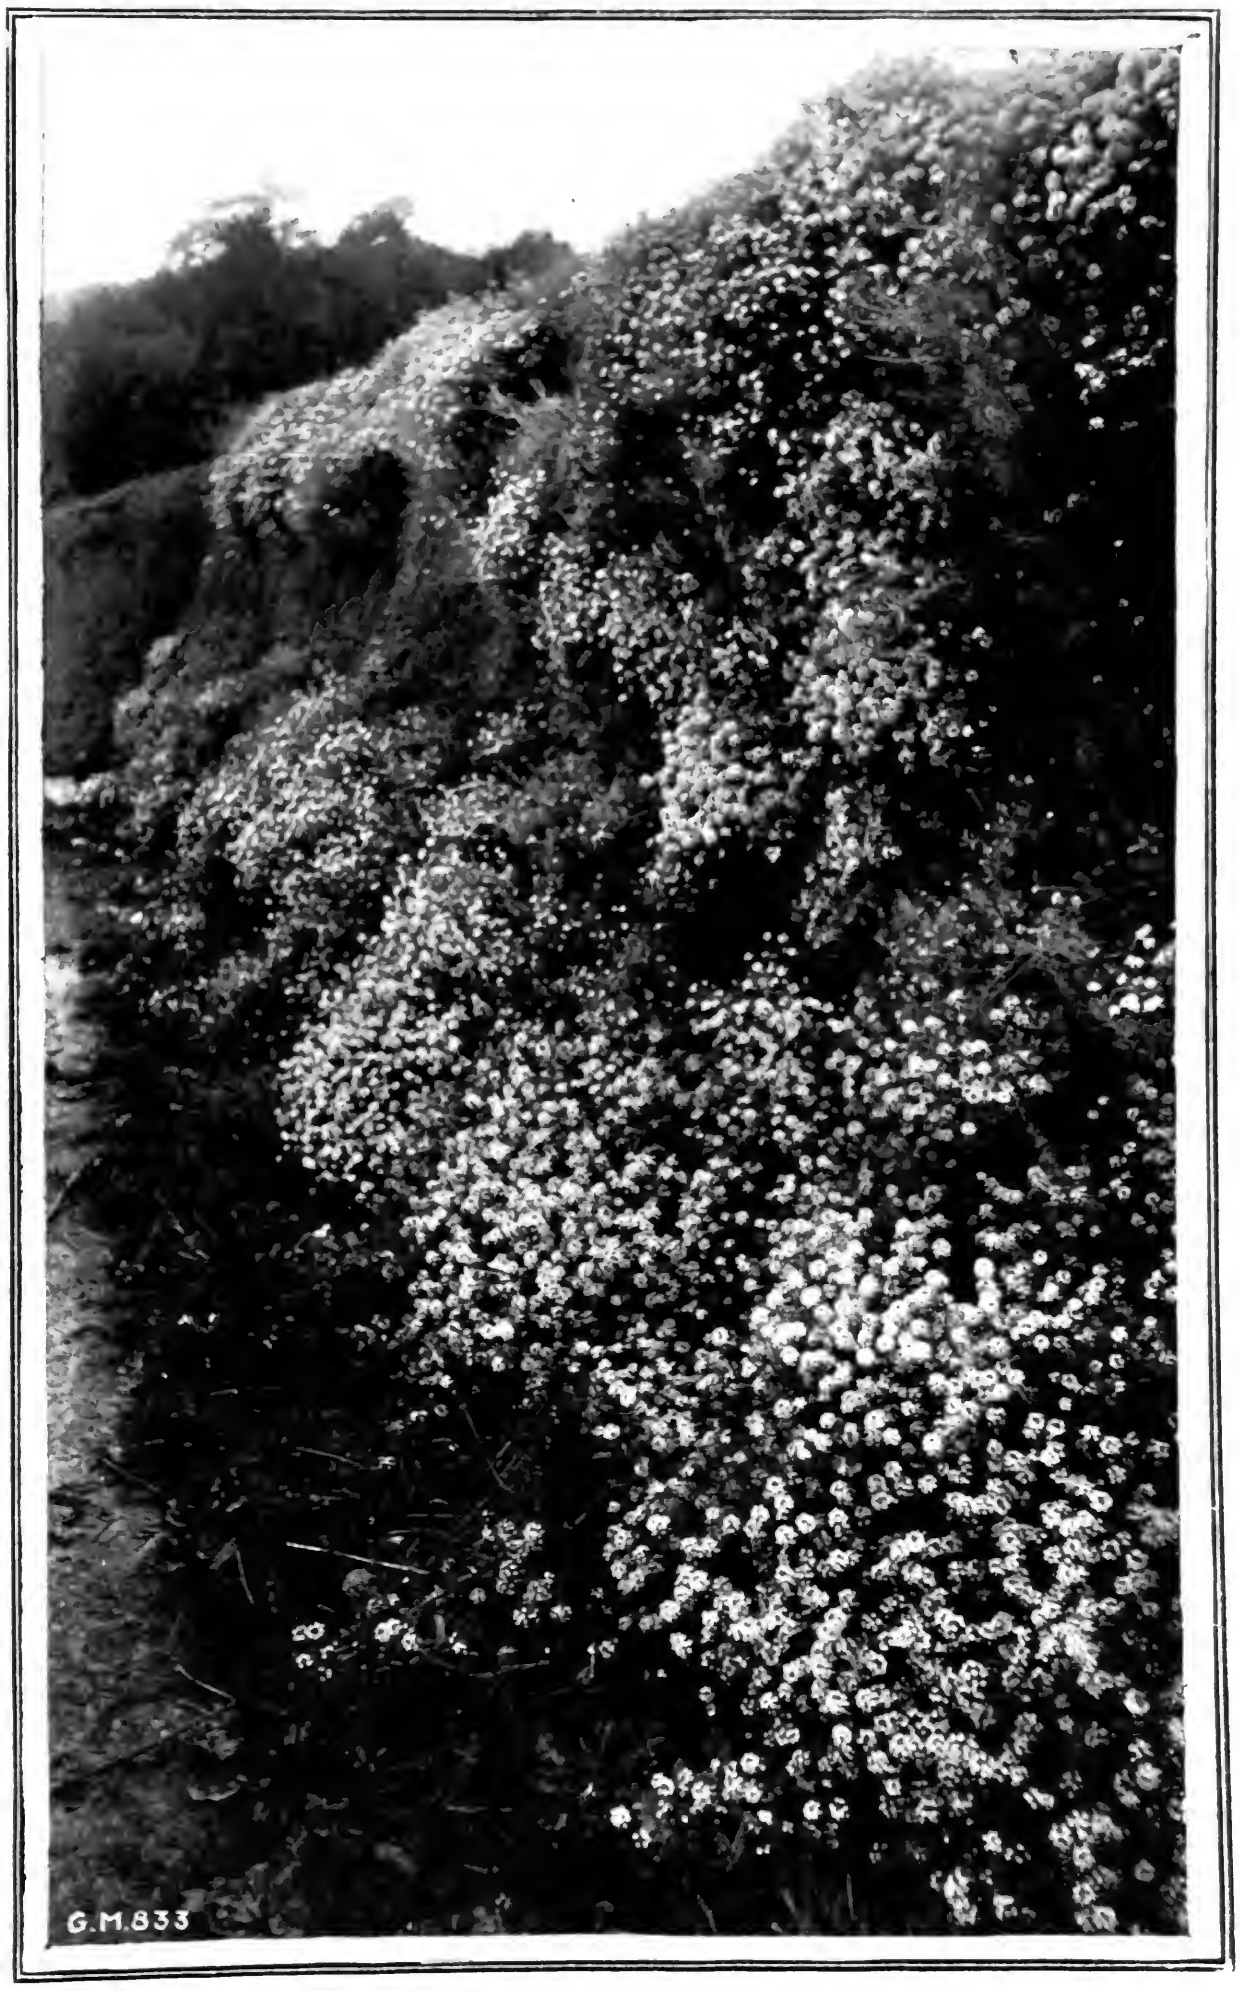
Disbudding requires careful attention, for if all but one of the buds on a stem are removed at the same time the bloom will probably come blind or malformed. Pay strict attention to the work, and examine the plants twice a week, so that the matter may receive attention at the right time. Look the plants over occasionally during the winter, and remove any diseased or dead foliage; but if the treatment outlined above is followed there will be little trouble with rust or other pests. Keep the plants neatly tied with green raffia, so that the growths may be held erect. Fumigate the house occasionally with nicotine compound to prevent the development of green-fly.

Perpetual-flowering carnations are chiefly grown for winter flowering, and after good plants have been obtained it is most essential they receive the correct treatment.

J. Gardner.

SWEET ALYSSUM.

The alyssums constitute a large genus, numbering about ninety species. There are probably, at the present time, not more than about a dozen really attractive kinds in cultivation, and some of these are, indeed, so closely allied that a fair proportion of them might be dispensed with altogether. There are a few annual species, of which the subject of this note is one, but, in many cases, in the warmer districts it will live through the winter,



SWEET ALYSSUM CLOTHING A STEEP BANK.

the plants shown in the accompanying illustration having remained in good health for some years. The majority are, however, perennial shrubby or half-shrubby plants, procumbent in habit, and, for the most part, evergreen.

The flowers, though individually small, are produced in such dense clusters, and in such great numbers, as to render this class of plants quite indispensable in spring and

early summer, both in the wild garden, the spring garden, and the rock garden. They are of very easy culture when rightly situated. Propagation of the perennials is effected by division and cuttings, the latter in the case of most species being much the safer way. Alyssum, or Kœniga, maritima, the sweet alyssum of gardens, is most satisfactory when treated simply as a hardy annual. The flowers, which are small and white, are borne in profuse clusters, and emit a delicious fragrance. It is a good plant for covering bare spaces, banks, or tops of unsightly walls, where it will sow itself from year to year. It may be used also as a carpet plant, but in rich soil it generally grows too robust, and does not flower so freely. It is found in waste places near the seaside, but only as a plant escaped from a garden.

In large colonies of this alyssum what attracts particular attention is the great mass of pure white blossom, that quite hides the foliage from view. Single plants a foot or more across are a pure white mass. Large spaces in the rock garden may be amply clothed with it in a short time. The plants shown in the illustration were the produce of self-sown seed. It is a native of Southern Europe.

Wyndham Fitzherbert.

PEROWSKIA ATRIPLICIFOLIA.

This plant belongs to the Natural Order Labiatæ, and its genus consists of four species, two of which are natives of Turkestan, one comes from Beluchistan, while the other is found over the greater part of the Himalayas from Afghanistan to Tibet. The latter, P. atriplicifolia, is a very handsome sub-shrubby plant, growing from three feet to five feet high. In some parts of this country it is usually cut down to the ground during the winter, but in the warmer parts it makes quite a shrubby subject.

Like many of the plants of this order it is strongly scented, much resembling the common sage. The stems are erect, and covered with a hoary tomentum, while the ovate leaves, about two inches long, have a scented margin. Branching towards the top the stems bear a large terminal panicle on the current year's growth. The silver-grey stems and flower stalks, bearing the violet-blue flowers, are very attractive during the autumn, and flowering takes place early in September.

Perowskia atriplicifolia is said to grow in large quantities in the Himalayas, where it makes a most effective display. While the prevailing colour of the flowers is dark lavender, a white form is met with in a wild state, but I have not seen it in cultivation. The species has been in cultivation since the year 1906, when it was introduced by the Messrs. Bees, Lim. It is easy to manage, and will grow in any well-drained soil in full sunshine. Owing to the late period of flowering it does not produce seed here, but it may be propagated freely by means of cuttings in early summer.

W. Irving.

Kew.

Acacia platyptera.—Nearly all the greenhouse acacias flower during the spring months, but this is quite an exception, as its blossoms, like little golden balls, are borne in the autumn. Apart from its season of blooming, another distinctive feature is the peculiar, green, winged stems which take the place of leaves, for it is practically devoid of foliage. For its successful culture, it needs a liberal amount of peat in the soil, and neat little flowering plants may be grown in pots from five to six inches in diameter.—T.

BERRY-BEARING SHRUBS IN WINTER.

Nothing enlivens our gardens more during the winter months than a good collection of shrubs bearing bright fruits. At one time almost the only shrubs we had of this class were the holly and Cratægus pyracantha, but now there is a host of kinds from a foot in height up to fair-sized trees.

After the deciduous trees and shrubs have shed their leaves our gardens would be bare were it not for the evergreen plants and those having showy fruit. Some of the deciduous shrubs, however, have interesting fruits. Take the symphoricarpus, for instance; the large white berries, hanging in graceful racemes, are very conspicuous long after the leaves have fallen. To see this plant to advantage it should be planted in bold clumps on a sloping bank on the side of a stream as the long sprays of large white berries are then very effective. Well-fruited hollies look well in almost any position.

The pernettyas, as most people are aware, thrive best in a peaty soil, and, when established, will berry most profusely, even when in a very small state; but if planted in loam, though they will make ample growth, it is seldom they fruit freely, though they may have an abundance of flowers. Plants about a foot high, grown in a sunny position, will produce clusters of variously-coloured fruit, and such are well adapted either for the rock garden or in groups in front of taller-growing shrubs. I have seen these grown to fair-sized bushes, from three to four feet high, and when they have attained this size they are very showy.

Skimmias, again, are most useful and with their thick, shining foliage are always interesting, but when clothed with clusters of red berries they are doubly so. I have always found these grow best in a light, rich soil, such as a mixture of peat and loam, to which some thoroughly decayed manure or leaf-soil has been added. Birds are not very fond of skimmia berries, so the display remains through the winter, and until quite late in spring. When planted in a sunny position skimmias usually fruit most profusely.

To obtain finely-fruited aucubas both male and female plants should be arranged near each other. The large red fruits are most showy during winter, as they are produced in prominent clusters on the young shoots. Both the green and variegated kinds are very useful. Hippophæ rhamnoides (Sea Buckthorn) is a deciduous shrub or small tree, and, as with the aucuba, the male and female flowers are produced on different plants, therefore to obtain a crop of fruit it is essential that both be planted together. In winter, when the foliage falls, the berry-bearing plants are very showy with their orange-red berries. These plants are most effective when grown as standards on stems from five to six feet high, and planted in groups over some dwarf-growing shrubs. There are several species of euonymus that fruit most profusely. Our own native species, E. europæus, which in some parts of the country grows wild in the hedgerows, is very ornamental. When grown as standards on tall stems, and planted in a sunny position, the foliage assumes glorious tints in the autumn, and after the leaves have fallen the peculiarly shaped fruits hang for some time. E. radicans, when grown against a building, assumes quite a different character, the foliage being much larger and almost white, and often the young shoots are clothed with the clusters of fruit, which, when ripe, are a great contrast to the foliage.

There are many interesting species of cotoneaster, and some of these, such as C. Simonsi, are attractive when grown either as bushes, standards, or against walls, the bright red berries being always conspicuous. It is, however, when trained against a wall, and the growths are treated as upright cordons, the finest effect is produced. Grown in this manner, and closely spurred in, the clusters of red fruit against a stone wall are very effective. C. applanata has brilliant scarlet berries, produced in great profusion. A. angustifolia is too seldom met with in our gardens. The berries are produced in clusters, or bunches, unlike those of most cotoneasters. I saw a plant of this at Hartpury last year that was covered with bunches of berries. The fruits do not ripen until late in the season, and remain quite fresh until the spring. To induce it to fruit freely the shoots should be thinned out. There are several cotoneasters of recent introduction, with very attractive fruit. C. Dielsiana elegans is one of these, and is an evergreen species bearing pink flowers, followed by bright red fruit. C. salicifolia glacialis is also an evergreen kind with deep red fruit. C. salicifolia rugosa is a semi-evergreen species, bearing coral-red berries.

The fruits of many berberis are very bright, but, unfortunately, where birds abound in great quantities they usually strip the bushes as soon as the fruits are ripe. B. vulgaris and its varieties are most useful. The old Viburnum lantana, which grows wild in our hedgerows, and V. opulus, which is so frequently met with in boggy places, are very showy, but, in addition to these, there are several species of recent introduction that are well worthy of notice. V. rhytidophyllum is one of these. It is an evergreen species, producing large handsome foliage and noble spikes of flowers. The other day I saw a specimen of it covered with clusters of dark red berries, which were very attractive. Then we have V. phlebotrichum, V. Henryi, V. Davidi, and others. Stranvæsia undulata is a handsome evergreen shrub that should find a place in gardens as its orange-red fruits are very effective.

H. C. Prinsep.

TODEAS AT GLASGOW.

Time was when todeas were subjects of awe to the visitor to the gardens where they were grown under carefully-studied conditions. Now, however, they are found to be quite easily grown, and one is pleased to see them in the best of health under conditions one would not always expect. The Kibble Palace in the Glasgow Botanic Garden is one of these. The pathway in the large central part of the structure was too broad, so it was decided by Mr. Whitton that it might be reduced in breadth by placing rockwork and soil in front of the pipes, which were rather an unsightly feature. This was done, and a number of todeas planted there along with other subjects. There they are doing splendidly, and are growing apace, and are forming big plants. In the Moss House, too, they have been planted instead of some of the commoner ferns which formerly helped to make this attractive house prettier. The conditions are very different, as the atmosphere of the Moss House is moist, while that of the Kibble is drier and airier. Yet in both the several todeas are flourishing equally well. Mr. Rourke, who is in charge of the Glasgow Botanic Gardens, deserves much credit for the success of these plants there.

S. A.

LIFTING AND STORING DAHLIAS.

Though as I write (October 23) the dahlia plants here are a mass of bloom, we must expect that any night the curtain will be rung down for another season, through the intervention of a few degrees of frost.

Usually in this locality we are fortunate enough to reach the end of October, and even the second week of November, before this happens, proof of which has been seen by many fine exhibits of dahlias by a well-known local firm at the Cardiff Chrysanthemum Show. Last year, however, was an exception, the visitation of six degrees of frost on the night of October 5 completely transforming a glorious display to a blackened mass.

Before it is too late it is wise to take the precaution of examining labels to see if these are in order, for where the system of placing the label in the soil close to the plant has been adopted some may easily have been displaced during working operations. No doubt the safest system of labelling is to fasten the label securely with copper wire to the stake. If a very small-size wire is used this is quite cheap, and undoubtedly so in the long run, as the same label can be used for winter storing. No good purpose can be served by delaying lifting after the plants are cut down by frost, excepting that a fine day, with, preferably, a drying wind, will greatly assist in preparing the tubers for storing.

The old stems should be cut down to within six inches or nine inches of the soil, and the roots carefully lifted with a fork. After removing any soil round and among the tubers, carefully secure the label round the base of a good tuber, not the stem, which will decay and may fall off, and place in an airy position to thoroughly dry before storing.

Where large numbers of plants, and especially of various types, are grown, the lifting should be carried out systematically, taking one section at a time, and dispose of all the plants belonging to it before proceeding with the others.

A very great difference will be found in the roots of dahlias, some varieties making a large mass of tubers, while others scarcely any. The latter shy rooters, of which the fine bedding, decorative Brentwood Yellow is an example, require more care in storing than the vigorous-rooters. The former must not be dried too much, or they may shrivel, and when ready no time should be lost before placing them in boxes or other receptacles, and cover with sand. For the larger roots sand or soil will be suitable, or even hay placed around and over them will be sufficient. It is imperative that whatever covering is used that it be thoroughly dry.

In the winter storing of tubers three cardinal points have to be kept in mind, viz., the avoidance of excessive heat, cold and damp. As to where they should be stored is solely a matter of convenience, and many and various are the places adopted by amateurs, from the attic to the cellar. Any building, be it loft, storeroom, or cellar, provided it is dry and the temperature about 40 degrees, will be suitable. Vineries, peach houses, etc., which are "resting," serve equally well if these can be spared and no objection is made to seeing them in the houses.

During the winter they must be examined occasionally to see that all is well. Should the slightest sign of damp, which usually shows itself in a mouldy form, be apparent, the affected part, if small, may be cut off, and the roots dusted with lime, or lime and sulphur. This is work which can be attended to in wet or bad weather, and a little timely attention in this respect may save much disappointment.

Arthur J. Cobb.

TULIP MASSENET.

New Darwin tulips were not numerous last spring; at least, few were honoured by awards, but now that these fine flowers are coming into their own place in our gardens the standard of quality needful for an award steadily rises. A beautiful variety which attracted considerable attention at the meeting of the Royal Horticultural Society on May 14 last was Massenet, with finely-rounded flowers of great substance, borne on stout stems. The colour, softest buff, with a deep flushing of rich rose over the centre of each segment is very distinct. We believe the variety was discovered in Holland, but it was exhibited by Messrs. R. H. Bath, of Wisbech, on the above date, and secured an Award of Merit.

DARWIN TULIP MASSENET.

Flowers pale buff, with deep rose shading over the centre of each segment. A.M., R.H.S., May 14. Messrs. R. H. Bath, Lim., Wisbech.

THE GARDENS OF ASIA;
SOME NEW ALPINES FROM TIBET.

Is it not strange that many of the most beautiful and delicately-formed flowers should inhabit the most savage mountains in the world, where, blasted by the howling winds, hammered by the pitiless rains, they yet spring up boldly amongst the rocks, and star the grass-covered slopes with spots of colour all the brief summer through, till the snow creeps down and covers them with a warm blanket, and the wind rattles their skeletons in vain! It is as though the monarchs of the mountains were alone worthy to stand watch and ward over the greatest treasures of the earth; as though none but the fiercest storms could breed so pure and noble a race of plants.

More than a year ago I climbed some of those desolate mountains which stretch away, range beyond range, from Western-most China into Tibet. Above was the silence of eternal snow; far below the rivers foamed and thundered over the rocks, smashing their way southward through endless gorges to the plains beyond. But here, all round us, were grand forests of fir and giant rhododendrons, of elder, birch, and bamboo; meadows of alpine grasses and stately flowers; and, still higher, stretching up towards the vast snowfields, a wealth of scattered gems, most brilliant of all flowers, painting with many colours a world of grey rock.

Those who delight in alpines and rock gardens will have seen some of these very plants this year, for many of them were on the market, as well as at the chief shows. A few I have seen again myself, growing in the quiet Cheshire nurseries of Bees, Lim., as well as in the Edinburgh Botanic Gardens—surroundings so different to those in which I had first found them that I scarcely recognised them as the same. Much as I love our English gardens, with their splendid array of hardy plants, spring, summer, and autumn, I must confess that, since fortune has taken me there, I love these plants even more in their wild haunts.

Throughout the brief Tibetan summer the very high alpine regions towards the extreme limit of flowering plants prove the happiest hunting ground.

Here is the neat little Primula bella, starring the grassland with its lovely purple flowers; the blue Primula brevifolia, with tall, loose umbels; and, most magnificent of all, P. dryadifolia, flaming in crimson patches on the limestone rocks. None of these are known in cultivation, though the last-named has been successfully raised at the Edinburgh Botanic Gardens.

In July the Cambridge-blue Meconopsis speciosa is flowering at an altitude of about 16,000 feet. What a wonderful sight to see this plant in full bloom, a stem about eighteen inches high bearing a raceme of eight or ten brilliant pale blue flowers, each an inch and a-half across, massed with golden stamens in the centre! Unfortunately, the meconopses, though perfectly hardy in this country, are not perennial.

Lower down is the Oxford-blue Meconopsis Wardii, a new species, named after the writer; it has, however, black instead of golden stamens, which detracts considerably from its beauty. A third species, M. rudis, a dwarf plant, with bluish-violet flowers, occurs on the alpine grassland at 16,000 feet, and all three species should be seen in England next year.

Down in the valleys, at 12,000 feet, the season opens as early as the middle of May with a few shade plants, amongst which we may notice Primula sonchifolia, a damp-loving plant, bearing close heads of large blue flowers with a yellow eye. Higher up, and consequently flowering rather later, is P. pulchella, another dwarf, with mauve flowers.

In June we can ascend above the forest limit, where, in the track of the melting snow, we may come across marshy ground scattered with the magenta P. Souliei, an anomalous species, each stem bearing a single large, slightly irregular flower. Here there will be a host of magnificent alpines, amongst which it will be sufficient to mention the sulphur Meconopsis integrifolia, already in cultivation in this country; the somewhat similar M. pseudo-integrifolia, recently lost to civilisation, and now again restored; Primula nivalis, a beautiful species, known only from a few plants raised in St. Petersburg Botanic Garden; and the pink Fritillaria Souliei.

It will be well to point out here that Western China is peculiarly rich in fine primulas. These flowers, which scarcely occur in the New World, and are but poorly represented in the Alps, have two great centres of distribution in Asia, one in the Himalayas, and the other in the province of Yunnan.

At the end of the summer the primulas will have all gone, and instead there will be, particularly at high altitudes, a wealth of saxifrages and gentians, forming the autumn flora. Saxifraga negroglandulosa which occurs in large tufts on the limestone rocks may serve as a type of the numerous yellow-flowered saxifrages, and Gentiana sikkimensis of the blue alpine gentians. But by far the most brilliant of the latter is G. ornata, with its long, trumpet-shaped corollas radiating out from a centre; a mass of these lying prostrate on the rocks is indescribably glorious. In this country the plant has hitherto only been raised at the Edinburgh Gardens.

Then there are the various cremanthodiums, with delicate nodding flowers, mauve or yellow. They grow in damp, shady places, and set so little good seed that it is almost impossible to raise them this way.

Androsace spinulifera, with massive heads of pink flowers, and the peerless A. Bulleyana, with smaller heads of carmine flowers, have been successfully raised in England, though neither is yet known to the public; but the unique Isopyrum grandiflorum, a limestone plant, bearing masses of semi-pendant, delicate violet flowers, has defied almost every attempt to raise it from seed.

The curious labiate Phlomis rotata, with four large cruciate leaves lying flat on the ground, should make a first-rate rock plant, and Primula sibirica, which is not unlike the beautiful P. malacoides in colour and habit, should also become popular.

The twining Codonopsis convolvulacea, which has been successfully grown at Edinburgh, and the dwarf blue Aconitum Hookeri, are also worthy of mention.

In the above list of alpines I have mentioned but a score of the best which I collected in Tibet last year. Not one of these is known in cultivation in England to-day, but next year may see some of them added to our gardens.

F. Kingdon Ward, B.A.

BARREN FERNS.

Normally, of course, all ferns bear their reproductive bodies, the spores, in one way or another, though they contrive to do this in various fashions, some in the shape of dots, lines, or patches, or even, as in the Staghorn Ferns (Platycerium) in evenly-spread masses all over the backs of specialised fronds. Others, like our Royal Ferns and many exotics, have parts of their fronds specialised to bear spores only, while others, like our Blechnum spicant, and the Lomarias, bear them on erect fronds of narrower type than the fertile ones.

Ferns, therefore, which are persistently barren can only be regarded as abnormal, and such barrenness is almost always associated with some further peculiarity. As a general rule the suppression of spore production seems to be co-related with increased foliar development, the energy of reproduction being diverted in that direction. The spore heaps are always, and naturally, developed on, and by, the vein system of supply, and, equally naturally, if the system of feeding-veins is relieved of the exhausting function of forming and nourishing many millions of spores, given healthy conditions, those veins, whose other function is the construction and nourishment of mere leafage, have, as a result, the more energy at their disposal for this purpose

We may illustrate this by the forms of Scolopendrum crispum, or the Frilled Hartstongue. Of these there are two sections—the crispum proper, or the perfectly barren one, and the fertile crispums, which are sparsely fertile, and reproduce themselves truly when sown from. With the crispum proper, the frills are perfectly regular, with even, or, it may be, regularly crenate, edges. The seedlings of the fertile crispums in their juvenile stage are equally regular, but no sooner do they commence to show the spore heaps than, in precisely the same ratio, the frills and regular edges suffer. This is simply because we shall find, on examination, that the furcate veins, which, in the true crispums, go right to the frond edges and form the frills by forking again and again, in the fertile crispums they are interrupted halfway by having to form, and feed, the spores, and, being thereby exhausted, fail to reach the edges, and do what we may term "crispum duty" as well.

In the Polypodium family, we have the cambricum forms, which are entirely barren, and in these we see the same phenomenon of diverted reproductive energy, with the result that while the normal fertile frond is only pinnate, or once divided, these barren ones are greatly widened, and divided again and again. Nature, however, is fully capable of undertaking both tasks, viz., great foliar development, associated with spore production, but it may be taken as a rule that the former is correlated with, at any rate, a diminution of the latter, if not with entire disappearance.

It is, however, a curious fact that the faculty of cresting which involves material

additions to the structural function of vein systems, does not seem to decrease spore production in the least, as the crests themselves may be crowded with spores. The number of quite barren ferns, i.e., those which never bear spores, is comparatively small. Among our native ferns it is only the true plumose forms of Polypodium vulgare (cambricums), Scolopendrium vulgare (crispums), and Asplenium trichomanes (incisums) which have maintained their sterility unquestioned.

There is undoubtedly much in seasonal influences and environmental conditions which may either stimulate or check spore production, so that a fern grown for many years under one set of conditions may be regarded as perfectly sterile, but, given a change, it will be fertile; or it may be, a secondary bud "mutation" in an offset may lead to fertility therein, though the parent remain as sterile as ever. We have a vivid recollection of a division of Athyrium f.-f. plumosum Barnes, reputed as always barren, which was most profusely fertile, while the others in the same frame, though really portions of one and the same plant, were quite barren.

It is to the extra development due to spore suppression that we are indebted for some of our most beautiful ferns, both British and exotic. Adiantum Farleyense, the Queen of the Maidenhairs, is one of them, as also are Polypodium Knightæ, and the splendid forms of P. glaucum and aureum, raised by Messrs. May and Rochford, and last, but not least, by Mr. Manda. In the Pteris family we have the examples of P. Childsi and P. Sommersi, both very beautiful plumose and crested forms of, we believe, P. serrulata which have not been found to bear spores, though long in cultivation, and a number of other instances might be cited.

Chas. T. Drury, V.M.H., F.L.S.

CHRYSANTHEMUMS AT GHENT.

As duly recorded in the report which appeared in our issue of the 1st inst., chrysanthemums of English growth were splendidly shown at the great International Exhibition at Ghent, which was held during the closing days of October. The private growers of these flowers in this country were admirably represented by Mr. Thomas Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, Add'estone, who contributed a magnificent set of Japanese and single varieties, the whole of the blooms being superbly developed. The display of flowers so impressed the members of the jury by reason of the high quality of the flowers and the taste evinced in their arrangement, that the highest award in the class was made with acclamation and the felicitations of the jury, who also recommended an increase in the value of the prize originally offered. The prize awarded by the jury was not the only honour that Mr. Stevenson received at Ghent for his splendid demonstration of British skill in the cultivation of chrysanthemums, for H.M. the King of the Belgians, after going round the show, sent for Mr. Stevenson, who was presented to the King. His Majesty complimented our great grower upon the result of his cultivation, saying he had never before seen such fine chrysanthemums, and for some little time was engaged in conversation with Mr. Stevenson, whom we most heartily congratulate upon his well-deserved distinction. His group, herewith illustrated, of cut blooms, both Japanese and singles, was indeed well worthy of the highest commendation.

THE ROSE SEASON OF 1913.

This has been a most erratic year for many subjects besides roses, and I greatly fear many rose lovers have not fared so well as we have in Mid and East Sussex.

During very early spring growth was more than usually precocious, especially in the case of wall roses and ramblers of the wichuriana type. Indeed, few of these ceased to grow throughout the whole winter; and yet our Northern and Midland friends were so heavily hit by the early and severe frost of November, 1912, as to lose a number of their plants, no matter what the position occupied. From Scotland I received many bitter complaints, coupled with sarcastic remarks about the "hardiness" of these roses.

When the east wind came early, we also suffered, and even in the sheltered spots roses were much injured by the wonderful crop of insect pests encouraged by mild weather, and fed by the persistent young growth. Where the attack against these was neglected they increased so as to completely cover the growth, and quickly spread all over the garden directly the weather conditions were at all favourable.

On the whole I was quite agreeably surprised, when pruning, to find such good pith and soundness at the base of wood generally, although we had a sharp spell just after the sap began to rise. At what should have been the height of summer we were rather punished by hot and dry air, accompanied by an unkind easterly wind. Much of our young growth assumed a distressed appearance, and attacks of mildew quickly followed. Prompt measures had the desired effect, and I am pleased to say there have been few seasons when less of this dreaded disease was present with us.

The greenfly, the rose maggot, and grubs were very troublesome at first, and the amount of hand-picking was greater than usual. Nothing but an early and persistent use of the finger and thumb seems thoroughly effectual with these pests.

As usual, some few roses did better than they generally do, and I do not remember Etoile de France so good in early and mid summer before. It is rather strange that this rose should burn and "ball in" so much, as it is apt to do until the autumn arrives, seeing the grand opening qualities of its parents—Madame Abel Chatenay and Fisher Holmes.

A rose that has been good all through the season here is Lady Hillingdon. At first this came too pale, and actually flabby with us in the open, and I was by no means impressed in its favour. It has had no demerits during the present season, however, and at the end of October I could cut a really fine lot of highly-coloured and exquisitely sweet-scented flowers and buds; and it did not cease flowering once.

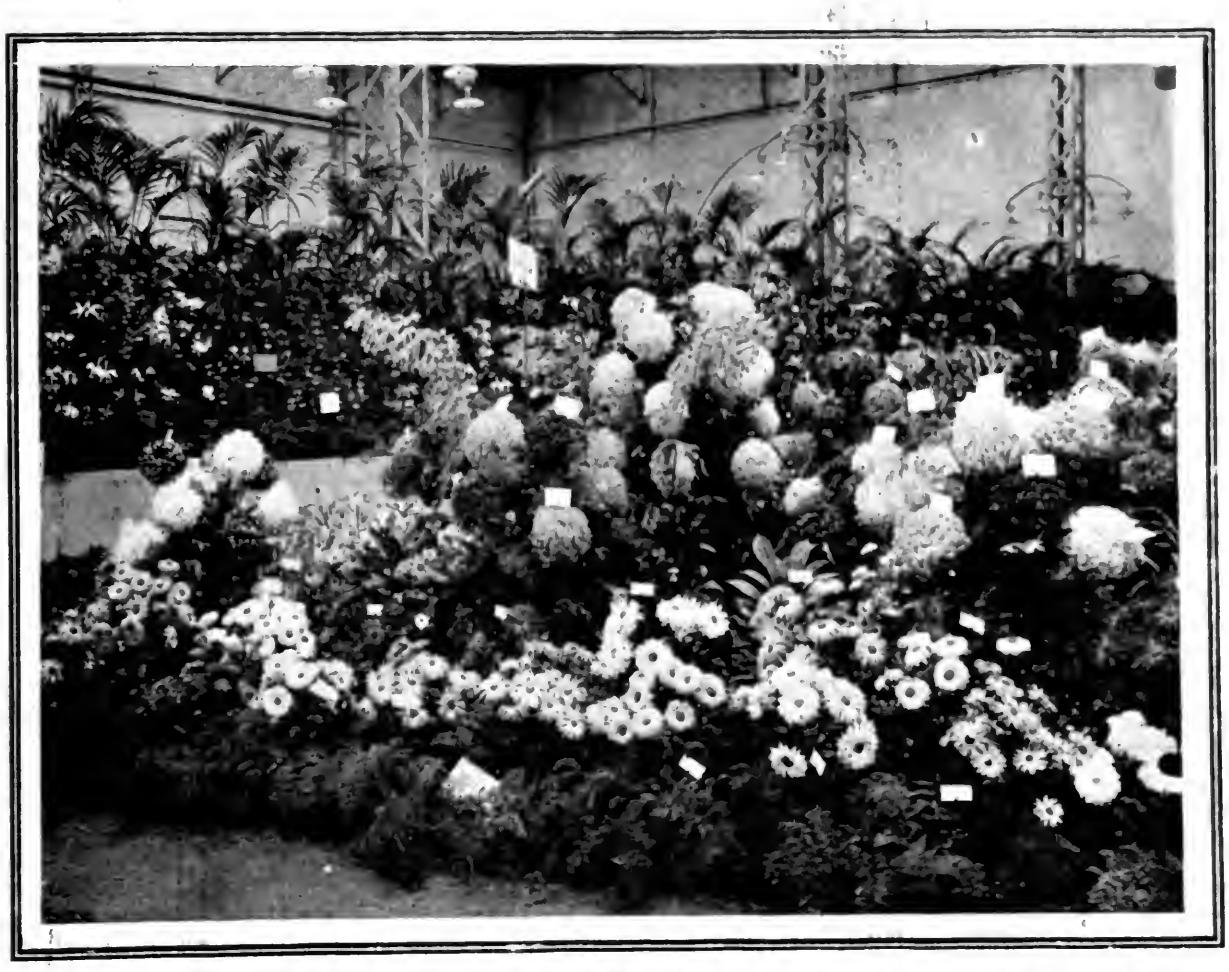
Three varieties from the newer Pernetiana group have been extra good all through the season. These are Lyon Rose, Rayon d'Or, and Arthur R. Goodwin. By the way, the sport from this, G. F. Barry, has been one of the best yellows. This only differs from the parent in its depth of deep primrose-yellow, that, like Rayon d'Or, does not fade. It is also a wonderfully sweet-scented variety, and will prove invaluable for beds. Beauté de Lyon and Louise Catherine Breslau have also been exceptionally good from this class.

The bulk of the hybrid wichurianas here have never been more constant in bloom, and quite a number have done well all the autumn. As I write, we have Alberic Barbier, Emile Fortepaule, and Mrs. Alice Garnier gay with flowers upon standards that were moved last winter.

At the early part of the budding season matters did not look at all promising, and we feared quite a number of stocks would not be active enough for favourable working. This was at the time of great drought and unkind winds; but it was surprising how soon the stocks answered to the change when it came, and at present I do not think there is any cause for complaint as to the promise of the buds, whether upon dwarf or standard stocks.

We have not had a first-class rose year, but the season has extended longer than usual, and has thus been fairly satisfactory all round.

Rosarian.



A FINE COLLECTION OF CHRYSANTHEMUMS AT THE GHENT SHOW.

Exhibited by Mr. T. Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, Addlestone, who was awarded the Grand Prix.

NEW PLANTS AND FLOWERS.

IRIS VARTANI WHITE PEARL.

This is one of the most charming irises of the reticulata group, and also one of the earliest to flower. I. Vartani is rich yellow, but the variety White Pearl is pure white. The leaves are slender, 6 or 8in. long, but the flowers only rise 3 or 4in. high. Originally collected as a wild form, I. Vartani White Pearl has been readily raised from seeds, and comes quite true. A beautiful addition to a delightful group of plants, and one that is hardy, but seems to lend itself especially to cultivation in a frame or cold house. A.M., R.H.S., November 4. Messrs. R. Wallace and Co., Colchester.

IRIS VARTANI WHITE PEARL.

A charming and beautiful bulbous iris of lowly habit, and producing pure white flowers. A.M., R.H.S., Nov. 4. Messrs. R. Wallace and Co., Colchester.

CYPRIPEDIUM OLYMPUS.

Not so very long ago such a fine cypripedium as this would have secured a First Class Certificate. It is a very large hybrid derived from C. Alcibiades and C. Leeanum Clinkaberryanum. The broad dorsal sepal measures rather more than 3½ inches across, and is white, with a green base and radiating lines of deep purple. The petals are tawny-yellow, shaded with red-brown, and highly burnished; the lip is similarly coloured, and very large. A.M., R.H.S., November 4. Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Gloucester.

CYPRIPEDIUM STELLA.

A lovely plant, bearing medium-sized flowers; its parents are C. Godefroyæ and C. Fairieanum. The influence of the latter parent is very obvious in the shape of the flower, and especially in the deflexed petals. The ground colour is cream-white, and this is freely strewn with rose-purple dots, chiefly grouped in lines on the dorsal sepal and petals, and on the elongated lip. A.M., R.H.S., November 4. Messrs. Sander and Sons, St. Albans.

CATTLEYA ANDREANA McBEAN'S VAR.

A very pretty orchid, with flowers of fair size. Sepals and petals soft and rich rose-purple overlaying a yellowish ground. Lip large, waved at the margin, deep golden-yellow, margined with rose-purple. The parents of this hybrid are C. Dowiana aurea and C. Mrs. Pitt. A.M., R.H.S., November 4. Messrs. J. and A. McBean, Cooksbridge.

SOPHRO-LÆLIO-CATTEYLA NIOBE.

This very neat habited and pretty orchid is the result of crossing Lælio-cattleya Gottoiana with Sophro-lælia Heatonense. The flower is of moderate size and of good shape, deep rose coloured, with a bright crimson lip that is very effective. A.M., R.H.S., November 4. Messrs. Charlesworth and Co., Haywards Heath.

LÆLIO-CATTLEYA OLENUS BLENHEIM VARIETY.

A large-flowered hybrid, very much resembling L.-c. Bletchleyensis, which, with C. aurea, were its parents. The flower shown lacked something in substance, but its broad petals and narrow sepals are very handsome; crimson-purple. The large ruby-crimson lip is marked with gold in the throat and base. A.M., R.H.S., November 4. The Duke of Marlborough (gardener, Mr. Hunter), Blenheim.

ODONTOGLOSSUM CRISPUM XANTHOTES WESTONBIRT VARIETY.

A lovely odontoglossum, with flowers of the finest shape and purest white ground colour, the whiteness enhanced by the rich golden-yellow spots on all the segments. A.M., R.H.S., November 4. Lieut.-Colonel Sir George Holford, Westonbirt.

CARNATIONS.

Gorgeous.—A showy perpetual variety of American origin; broad-petalled, of good size and shape, with capital stem and calyx. The colour is rich cerise-scarlet. A.M., R.H.S., November 4. Messrs. Stuart Low and Co., Enfield.

Champion. — This is a very fine scarlet perpetual variety, also hailing from the United States. The broad petals have fringed margins, and make up a bold, good-sized bloom, and the colour is a bright and rich shade of scarlet. Whether this will be the champion scarlet variety so long sought remains to be seen, but it is certainly very promising. A.M., R.H.S., November 4. Messrs. W. Wells and Co., Merstham.

CHRYSANTHEMUMS.

Pink Pearl.—A medium-sized Japanese variety, with silvery mauve-pink flowers; the florets flattish, smooth, and drooping slightly. Very attractive. A.M., R.H.S., November 4; F.C.C., N.C.S., November 5. Messrs. H. J. Jones, Ryecroft Nursery, Lewisham.

Daily Mail.—A bold, straw-yellow Japanese variety, already described and figured in our columns (see p. 849). A.M., R.H.S., November 4. Messrs. W. Wells and Co., Merstham.

Madme Th. Morel. — A large Japanese variety of fine exhibition type; the florets broad, and regularly reflexed to form a deep bloom. Colour, pale yellow, with a fawn or buff tint. A.M., R.H.S., November 4. Messrs. W. Wells and Co., Merstham.

Golden Mensa.—This fine, large-flowered single variety is a clear yellow counterpart of the popular white Mensa. A.M., R.H.S., November 4; F.C.C., N.C.S., November 5. Messrs. W. Wells and Co., Merstham.

Mrs. R. C. Pulling.—This is a large exhibition-sized Japanese variety, with loosely incurving florets. Colour, clear light yellow. Promises to be very popular. F.C.C., N.C.S., November 5. Messrs. H. J. Jones, Lim., Lewisham.

Mrs. H. J. Jones.—One of the largest and deepest of Japanese chrysanthemums. the florets long and graceful. When first opened, the colour is soft yellow, with a greenish tint, but the green soon fades, and the colour becomes deep lemon-yellow. F.C.C., N.C.S., November 5. Messrs. H. J. Jones, Lim., Lewisham.

Mrs. J. Gibson. — An attractive single variety, with shapely flowers, mauve-pink on a white ground. F.C.C., R.H.S., November 5. Messrs. W. Wells and Co., Merstham.

Isobel Felton.—One of the very largest of single varieties, many of the flowers measuring seven inches across. The florets are stout, and the flowers stand well. Colour, light and bright yellow. F.C.C., R.H.S., November 5. Mr. Norman Davis, Framfield, Sussex.

Buttercup. — This golden-yellow single variety promises to become very popular, its rich shade of colour and fine shape attracting general attention. F.C.C., R.H.S., November 5. Mr. G. Mileham, Emlyn Gardens, Leatherhead.

Rosalind. — A Japanese variety of medium size, of decorative or market style. The colour is a ruddy bronze. F.C.C., N.C.S., November 5. Messrs. Cragg, Harrison, and Cragg, Histon, Hounslow.

J. W. Streeter.—A fine primrose-yellow sport from the white incurved variety H. W. Thorp. It is very free-flowering as shown, one plant carrying eighteen blooms. Section I., b. First Class Market Certificate 93.28 points out of 100. October 13. Messrs. Cragg, Harrison, and Cragg, Merivale, Heston, Hounslow.

THE LESSER KNIPHOFIAS.

The charm of the lesser kniphofias is apparent to all lovers of hardy plants, and although they are not so widely utilised as they deserve, yet there are signs that the daintier torch lilies are gradually coming into their own. I have written previously of their great value for rock garden adornment. They are grand for any sunny piece of rockwork, and I am making greater use of them each season, as they are so brilliant in colour and continuous in blossom.

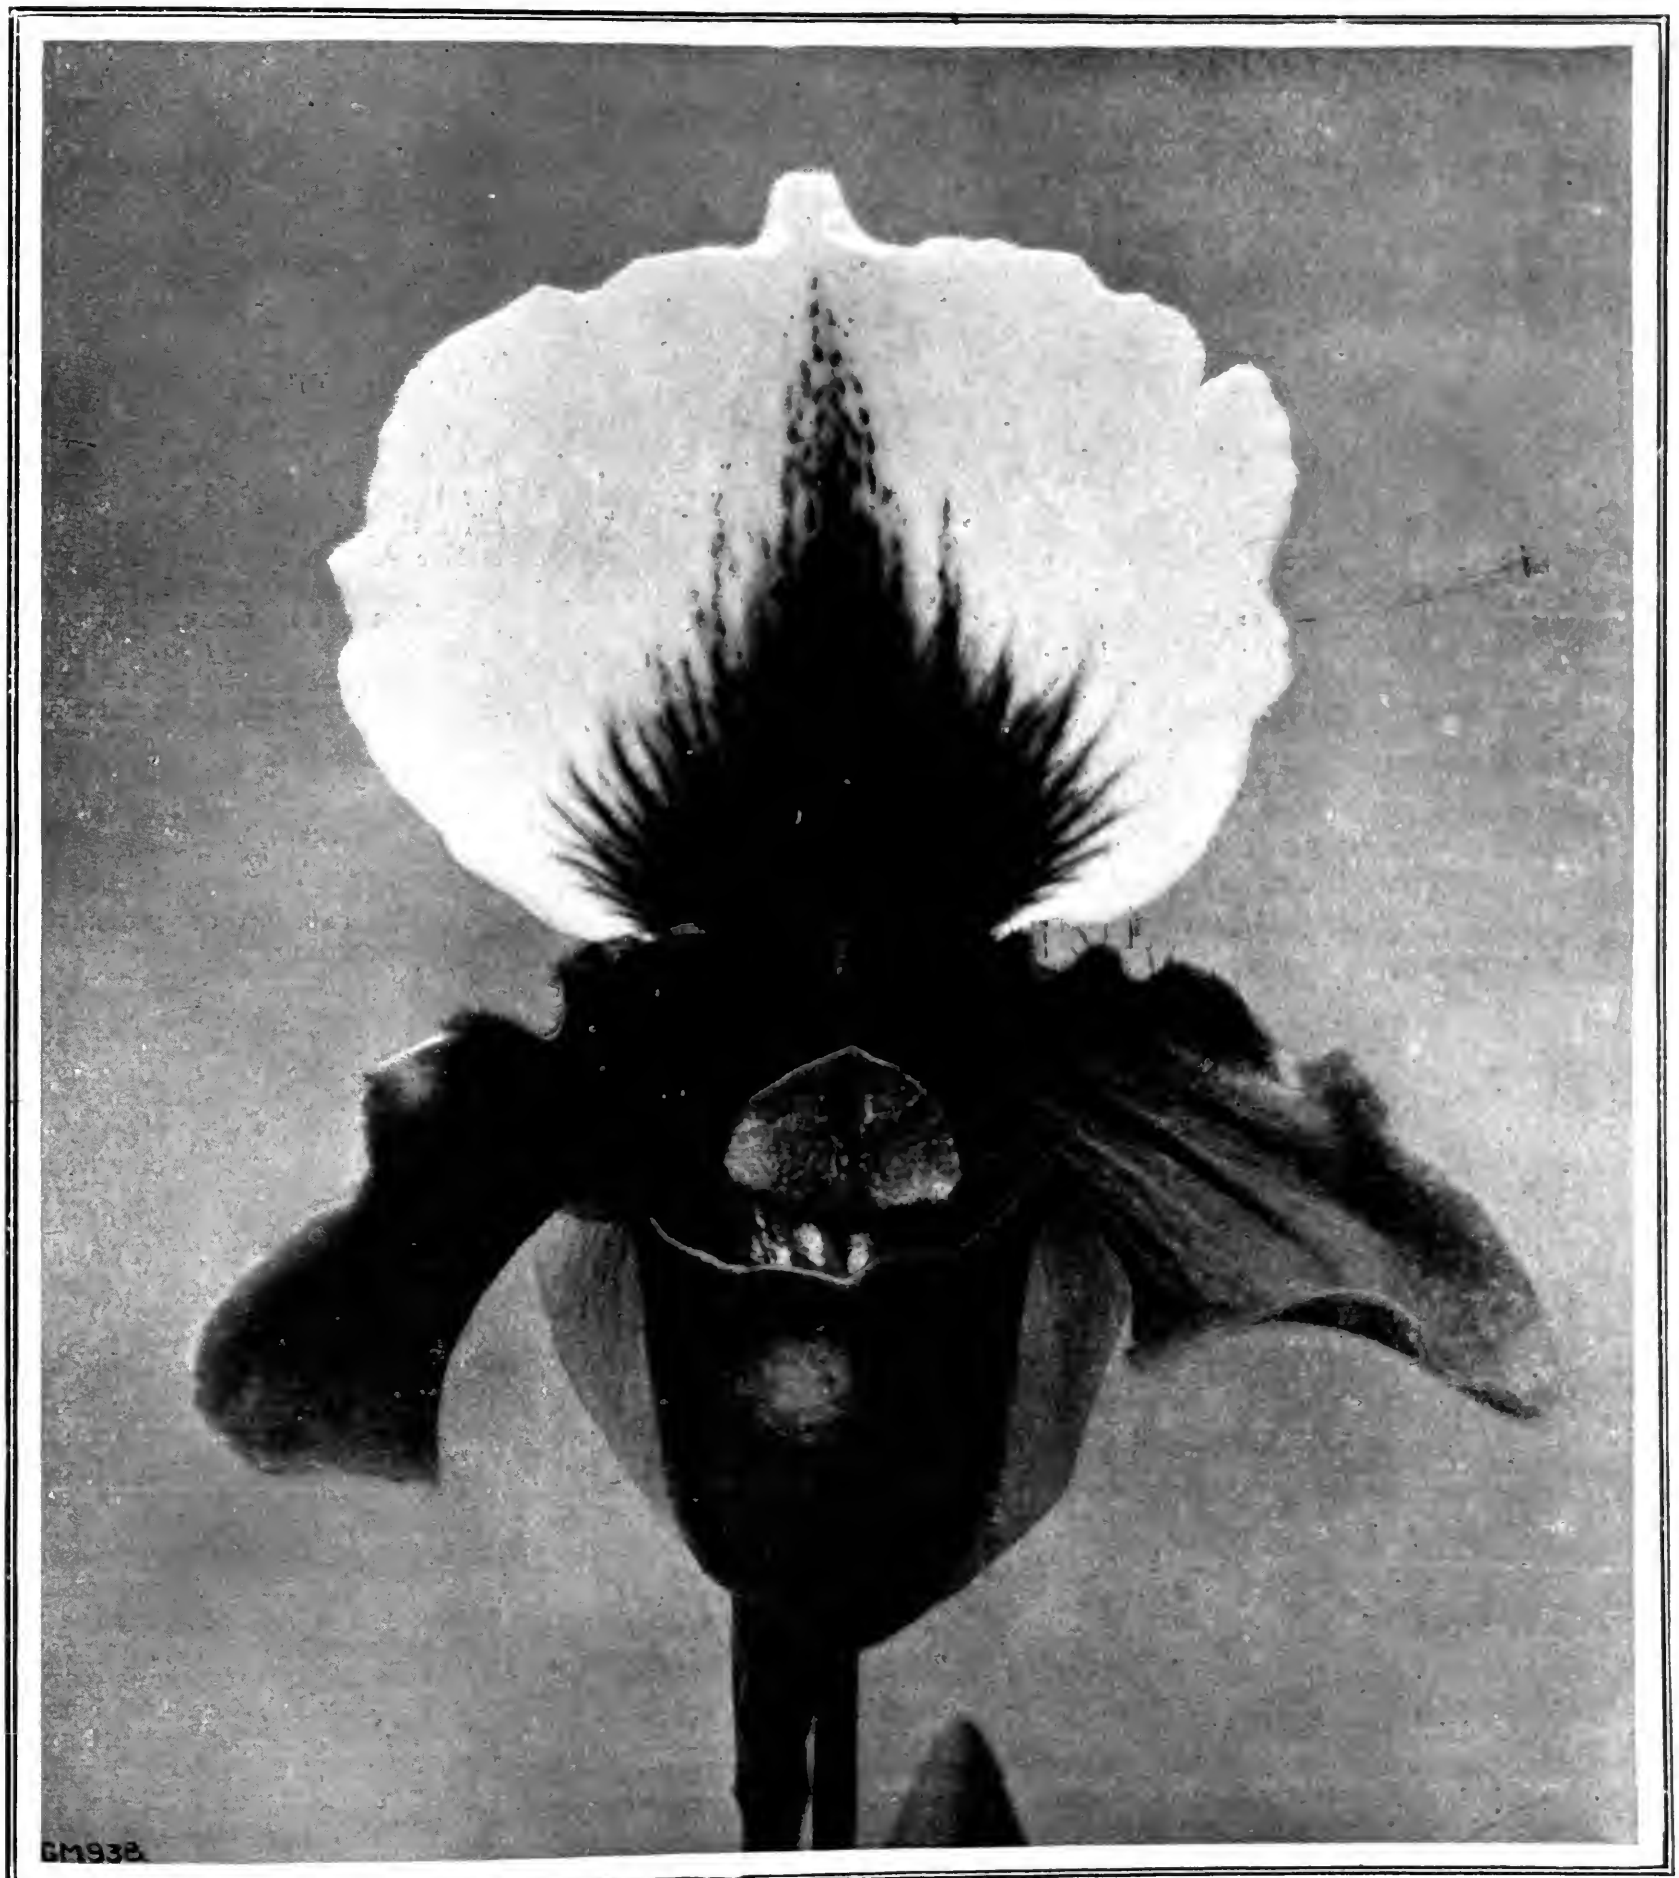
An open situation, with a deeply dug, moderately manured, loamy soil, will suit them perfectly, and if sufficient water is given in dry weather to keep the foliage from yellowing at the tips, and the surface of the soil is kept clean and stirred, little difficulty will be presented to the cultivator.

A brief chat concerning a few of these lesser torch lilies may be of service to readers. K. Nelsoni is one of the best known, a real delightful gem, which produces hosts of dainty flame-coloured blossoms from the wealth of grassy foliage. K. Goldelse, a pretty pure yellow hybrid, is a great favourite of mine, and should be found in every garden. K. Torchlight, a charming companion to the last-named, differs only in its colouring, which is of a bright flaming orange—a very showy and continuous form. G. pauciflora is yellow; a slender, graceful plant of great beauty and decided garden value. K. breviflora, somewhat on the same lines, but with shorter blossoms, is also worthy of note. It carries a pretty yellow shade of colour, and is tall, and very slender. K. rufa I think delightful, a real beauty, with its distinct colourings of fiery red above and bright yellow below. It is tall, free, and very dainty, and I would widely commend it for its beauty.

K. Modesta, the creamy-white kniphofia, can be classed with this smaller section. It is not quite so hardy as most, yet I think it can be safely wintered in England in the majority of gardens if a little protection is given it. Some charming hybrids and seedlings of Modesta have been raised, but I do not know if these are obtainable now. Some very quaint and unusual shades were to be met with among them, not brilliant, but decidedly original.

K. longicollis, one of the most recently-introduced species, can also be included. This is a soft yellow, tinted with orange, and flowers rather late in summer. It is free and beautiful, a very pretty addition to the class.

P. S. Hayward.



CYPRIPEDIUM OLYMPUS.

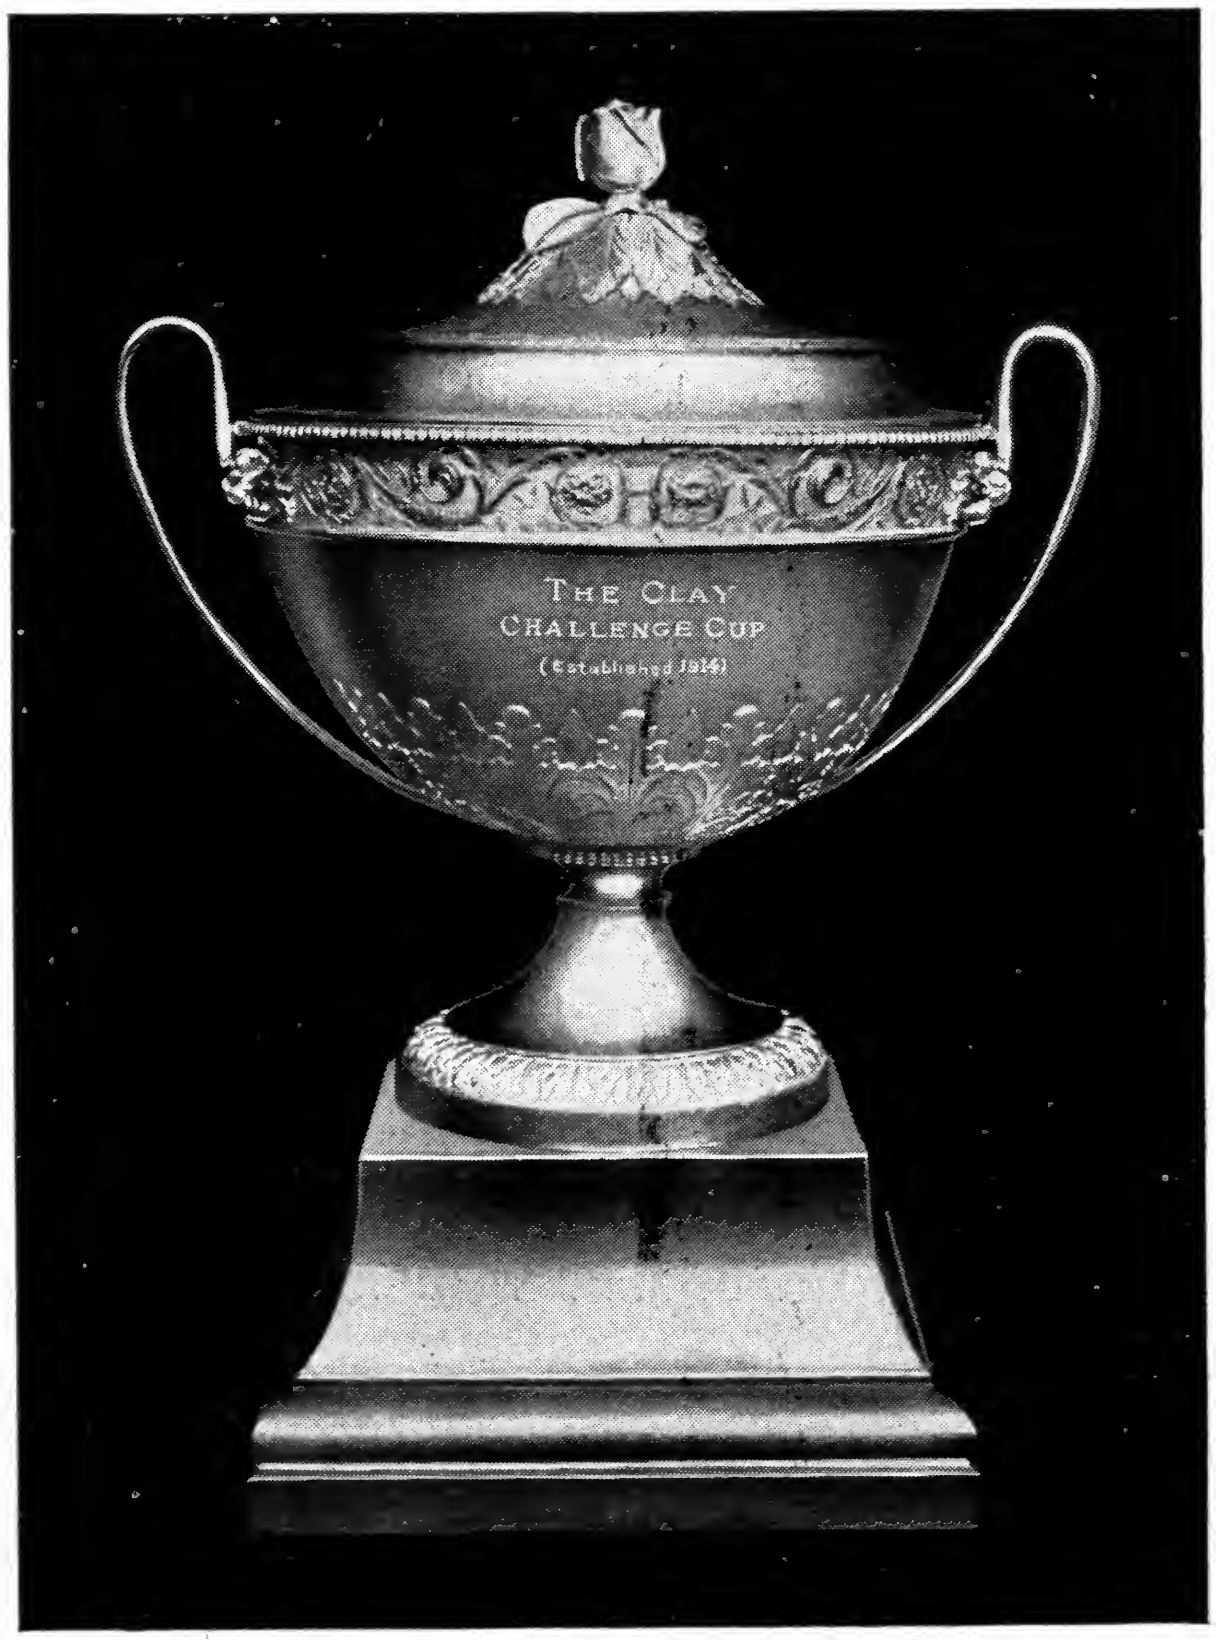
A very fine, large, Lady's Slipper orchid, with white, green-based, purple-line dorsal sepal, and tawny yellow and red-brown petals and lip. A.M., R.H.S., November 4. Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury, Gloucester.

I would commend them, not only for the rock garden, but also for bedding out for a summer display.

Planted in beds in the grass, with a groundwork of lesser plants (as a type of what to use I may mention violas), these smaller-growing kniphofias, with their slender, grassy foliage and graceful wealth of torches, make an exquisite picture. They are light in appearance, very effective and brilliant in hue, and create some very artistic groupings.

CHALLENGE CUP FOR FRAGRANT ROSES.

In our issue of the 1st inst. we were able to announce that Messrs. Clay and Sons had presented to the council of the Royal Horticultural Society a silver-gilt challenge cup of the value of 75 guineas, for the purpose of encouraging the development of fragrance in roses; and we have now much pleasure in presenting our readers with an illustration thereof. This fine example of the silversmith's art is to be offered for annual competition at the Holland House Show, and its object is to encourage raisers in the endeavour to obtain a race of roses with flowers of good form and colour, and possessing "the true old genuine rose scent, such as may be found in the old cabbage or Provence rose." suffice to say that the cup is silver-gilt in two colours, and bears upon one side the inscription, "Clay" Challenge Cup (established 1914); and upon the other the crest of the Royal Horticultural Society. The height, with pedestal, is 18 inches, the width 13½ inches, and the weight 90oz. It may be added that this fine cup is in every way worthy of the donors, the society, and Messrs. Elkington and Son, the makers.



SEVENTY-FIVE GUINEA CHALLENGE CUP FOR FRAGRANT ROSES,
Presented to the Royal Horticultural Society by Messrs. Clay and Son.

The perfume known as the "tea scent" is, we learn, to be excluded from the consideration of the judges in making their awards, and we assume the "musk scent" also will not be taken into account. The competitors for the cup will be allowed to stage a number of new roses, not exceeding three varieties, and from three to six blooms of each variety must be submitted. For five consecutive years Messrs. Clay and Son will also give a smaller commemorative cup which will be presented by the council of the Royal Horticultural Society to the winners of the challenge cup, when, at the end of twelve months, it is returned to the society.

The accompanying illustration so admirably portrays the elegant design for which the cup is remarkable as to render a lengthy description unnecessary. It will therefore

FLORAL DECORATIONS.

I have read with great interest the correspondence in your paper on "Table Decorations." As an exhibitor, I do not agree with Mr. Wise that the general style of decoration put up in rustic vases is altogether easy. Has he ever used these stands? If not, let him try, and see what he can do with a few flowers and a little foliage. I consider the rustic stands have been most useful to the majority of competitors, and the tubes, which some seem to think unsightly, can easily be hidden by a little artistic arrangement of foliage. At the same time, I do not favour these stands for all flowers, such as roses, chrysanthemums, and other heavy blooms; a low decoration and heavier vases are much nicer. But this style of decoration does not suit the majority of judges, whom, I may safely venture to say, are almost invariably gardeners.

Another point is height. No restriction should be made in this; it would result in monotony. Not enough scope is given to the competitor, and the generally expressed opinion of the public is, "What a sameness there is in these tables." And the public are the best critics. All competitors would welcome something new in the art of decorating, and I hope Mr. Wise will come forward at one of the forthcoming exhibitions and show competitors how to decorate a table fit to be seen in a gentleman's house. He would do well to visit the National Rose Society's show, and see for himself that rustic vases share equally in the awards with silver vases and bowls.

Points should be given for artistic arrangement, good blooms, artificial light, effect, style, etc.; and the rules should also state whether the decoration is for the centre of a table, or for the whole of the table. Finally, I think the various show committees would do well to appoint younger judges with newer ideas, and let those of twenty or thirty years' experience retire. There are always plenty of critics at the various shows, but few have the pluck to do anything new and original. (MRS.) A. R. BIDE.

Highlands, Farnham.

R.H.S. RULES FOR ENTERING DAFFODILS FOR AWARDS.

At their meeting on the 4th inst., the President and Council of the Royal Horticultural Society adopted the following new rules submitted by the Narcissus and Tulip Committee of the Society. The rules will take effect from January 1, 1914.

1.—It must be clearly stated on the entry form of any variety which is submitted to the committee for an award, under which of the following heads the sender wishes it to be judged—

(a) As a show flower, or "show."
(b) As suitable for garden decoration, or "garden."
(c) For growing and flowering in pots, or "pots."
(d) For cutting or market purposes, or "cutting."
(e) As a plant for rockwork, or "rockery."

N.B. Any one variety may be entered under more than one head.

2.—The following conditions must be complied with in all cases:

If submitted under (a) five stems with bloom are necessary for an Award of Merit, and twelve stems for a First-class Certificate.

If submitted under (b) and (d) for either Award of Merit or First-class Certificate twenty-five stems must be submitted in two vases; twelve must be bunched and thirteen be loose.

If submitted under (c) and (e) two pots or pans must be shown, each containing not less than three bulbs, for an Award of Merit. Four pots or pans, each containing not less than three bulbs, for a First-class Certificate.

3.—Official entry forms will be provided, and may be obtained from the R.H.S. offices. One of these forms must be properly filled up by the exhibitor for each variety before it can be placed before the committee.

4.—The words "Show," "Garden," "Pots," "Cutting," or "Rockery," will in future be added to the usual A.M. or F.C.C.

Broccoli.—The mild and wet weather we have experienced of late has caused sappy growth in most of the brassicas, and broccoli in particular will require special care to enable them to pass through the winter safely, should it be at all severe. The best method of treatment is to heel over the plants with their heads to the north, covering the stems with soil right up to the lower leaves. Unless the soil covers the whole of the bare stem, frost will do much damage, as that portion of the stem just below the leaves is most susceptible to harm. Should the weather be extra severe, bracken or loose litter scattered over the plants will afford adequate protection. The early autumn varieties may be lifted with good balls of soil and planted in pits, and they will supply good heads up to Christmas.—W. MESSENGER

Winners of the CHAMPION CHALLENGE TROPHY NATIONAL ROSE SOCIETY, 1913,

AND ELEVEN TIMES PREVIOUSLY.

THE FINEST STOCK OF ROSES IN THE KINGDOM.

The Roses offered this Season are grown on maiden land, the plants are very strong with good roots, and are certain to give satisfaction. As a proof of their excellence they have won for us during June and July fifteen Challenge Cups, including the Champion Trophy of the National Rose Society, the King's Cup at Windsor, and numerous Medals and First Prizes throughout the country.

FRUIT AND ITS . . . CULTIVATION

By T. W. SANDERS, F.L.S., F.R.H.S.

Send for Illustrated Prospectus.

This up-to-date work truly may be termed an Encyclopædia of the Whole Art of Growing Fruit with Success. No matter whether the problem is to grow fruit in the Garden, Orchard or Plantation, herein will be found sound and practical information. Although written in the interests of fruit growers of all degrees, special attention is devoted to the requirements of Amateurs and those who desire as Small-holders to grow fruit for profit on their holdings. A splendid guide to a profitable pursuit.

PRICE SIX SHILLINGS NET (By Post, 6s. 4d.)

Crown 8vo, Cloth. 352 Pages. 64 Plates. 145 Plans and Diagrams.

CONTENTS.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

PLEIONES.—When grown in large pans the early-flowering P. maculata and P. lagenari make a fine display at this season of the year, and smaller specimens are exceedingly serviceable for decorative purposes. We find that they take no harm when employed in the dwelling-house if kept reasonably dry while in the rooms. As soon as they pass out of flower, the growth develops rapidly, therefore repotting should be attended to as soon after the flowers have been removed as possible. In the case of larger specimens, annual repotting is not necessary, but all dead and decaying matter about the surface of the compost should be removed. The surface moss, owing to the prolonged resting period, usually dies, and this should give place to living moss, carefully washed before use, as sphagnum is usually infested with small slugs, or eggs of slugs, at this season. When repotting large specimens, choose a lasting compost of good turfy loam, sphagnum, and fibrous peat in equal portions, with sufficient finely-broken crocks and sand added to render the compost porous. The plants should be placed about two inches apart, and the compost made moderately firm about the roots. Smaller specimens should be annually repotted, and if a little decayed leaf-soil is mixed with the compost we find the plants root more freely. Ample drainage must be given, and water afforded sparingly until the new roots become established in the fresh compost. The plants should be suspended from, or placed in a position near to, the roof-glass in a warm intermediate house for the winter months.

ANGULOAS.—The various species will now have completed their growth, and may be removed to cooler and more airy conditions to rest. It is not desirable to withhold water altogether until after the leaves have fallen, then only sufficient will be necessary to keep the pseudo-bulbs plump. Place the plants in a position where they will have the full benefit of all available light, for on the maturation of the pseudo-bulbs the success or failure of flowering in the spring will depend. Many of the lycastes have completed their growth, and will require less root moisture, but sufficient must be supplied to keep the leaves and pseudo-bulbs in good health. Cooler conditions, but not a too dry atmosphere, will assist the plants of this group during the short dormant season.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

LUCULIA GRATISSIMA.—If a suitable place can be found in the greenhouse or conservatory for this plant it should certainly be grown, for there is no more beautiful subject among our greenhouse shrubs. To grow it really well it should be planted in a restricted border. A suitable compost consists of fibrous loam, peat, or leaf-soil, and coarse sand. A frequent cause of failure, I believe, is keeping it too warm during the resting period, and this fact should be borne in mind when choosing the position in which to plant it. The most successful example of this beautiful plant that I ever saw was growing in a small greenhouse, in which the temperature dropped very closely to freezing point during severe frost. After the plants have finished flowering, which is usually by the end of the present month or early in December, the old wood should be cut hard back. Between pruning time and the spring the plants should be induced to rest by keeping the atmosphere cool and withholding water. They will then burst freely into strong growth in spring, and will have the whole of the summer in which to perfect their flowering shoots. One of the chief characteristics of Luculia gratissima is the delicate fragrance of its beautiful rose-coloured flowers.

LAPAGERIAS.—These plants require very similar treatment, both as to rooting medium and general conditions, as the luculia. Being a climbing plant it needs an overhead trellis for its long shoots, and where the flowers can be seen to advantage. By planting the red and white forms together, a fine contrast is produced, especially when the growths of each variety intermix. Great care is needed during the growing season to keep the shoots from becoming an entangled mass which should quite spoil the effect when the plants are in flower.

EARLY-FLOWERING BULBS. — The Paper White narcissus will need little forcing this season to flower them by Christmas. The bulbs which we potted up in September are still in cold frames, and are on the point of bursting into flower. Roman hyacinths, too, will not require to be hurried unless they are wanted at an early date. The early tulips are giving promise of success as the pots are becoming well filled with roots.

VIOLETS IN FRAMES.—The weather up to the time of writing has been very favourable for these, as, except during heavy rains, the lights have not been on, the frames either day or night. To keep violets flowering all through the winter there must be no semblance of coddling, and it is only during very severe frost that the frames will require to be tightly closed. Examine the plants frequently, and remove dead flowers and foliage; keep a sharp look-out for slugs, and dust the sides of the frame frequently with lime.—E. HARRISS, Lockinge Gardens.

HARDY FRUITS.

PLUMS.—As soon as the leaves have fallen pruning may be taken in hand and pushed forward when the weather is mild. Top-dressing at intervals of a few years will greatly assist the trees in the production of clean fruits and healthy growth, but when this work is performed it should be done thoroughly, getting well down to the main roots, and, if possible, bringing some of these nearer the surface. Remove all the old top soil, and give a good dressing of lime rubble and bone-meal, working this well down with a fork; then top-dress with plenty of good loam and lime rubble, laying out the roots as the work proceeds. Afterwards apply a good mulch of half-decayed manure. When pruning plums, lay in a fair quantity of young shoots, as I find it is from these young growths that the most and best fruits are produced: spur back the side growth on the main branches to within a couple of eyes; lay in the leaders neatly and straight, shortening them more or less according to the strength and maturity of the wood. If mussel scale is present, dress with caustic wash. Although the plum crop at Wrotham has been under the average on walls this season, two trees of Gisborne's, right in the open, in fact situated in a very exposed position, both cropped heavily, and the same was the case with one Victoria, a standard.

GOOSEBERRIES.—Pruning may be commenced now that most of the leaves have fallen. Some growers, however, prefer to leave them until spring, but if taken in hand at the present time the work can be got through quicker than when the weather is cold. Keep the heads well thinned out and the branches evenly distributed, so that when finished the bushes may have a good appearance; shorten the inner growths to within a few buds of older shoots, and, if the leaders are long, cut them back to within 12 or 15 inches of last year's wood. Leave, at intervals, young growths springing from the base, to take the place of any that may have to be removed next year. Rake up all the prunings, remove a portion of the top soil from beneath the bushes, dust well with fresh lime, and top-dress with loam and manure. Gooseberry bushes are frequently neglected, consequently the fruits are small and poorly flavoured, and the crops light. Syringe the bushes with quassia extract, and dust with soot and lime to render the buds distasteful to birds; and should the feathered tribe become very troublesome, strain black cotton at intervals and at different heights above the bushes, attaching it to bamboo stakes pushed into the ground.

PLANTING, ETC. — Proceed with the planting which remains to be done, and if the land is rather wet and sticky place some potting soil, or some other material moderately dry, among the roots, and do not tread too heavily until after the land is somewhat drier. See that all standard trees are neatly staked, and the ties renewed if needed. Afford protection against cattle, hares, and rabbits. Newly-planted trees will need only temporary supports until after they have settled and the soil has become more consolidated. In grass orchards keep the grass well grazed by sheep or cattle, and feed older trees with plenty of farmyard liquid; this may be applied at a much greater strength at this season of the year. If possible, keep poultry in the orchards, as their excrement is most beneficial to the trees.—H. MARKHAM, Wrotham Park Gardens.

THE KITCHEN GARDEN.

CUCUMBERS.—Plants now fruiting will require constant attention to keep them in a healthy condtion. All lateral growths should be closely stopped at a fruit joint, and trained in thinly; where the foliage becomes somewhat crowded remove some of the older leaves. If too much growth is allowed to remain the plants become weak and fail to crop satisfactorily. Avoid over-cropping. Light top-dressings of good loam and well-rotted manure should be applied frequently to encourage root action, and an occasional application of an approved artificial manure will be helpful. A brisk heat should be maintained and on sunny mornings syringe freely to keep down insect pests.

PEAS.—About the third week in this month, the earliest batch of peas for growing under glass may be sown. Eight-inch or ten-inch pots, well drained, are the most suitable for this purpose. A compost consisting of three parts good fibrous loam, one part leaf-mould and old mushroom-bed manure, should be passed through a half-inch sieve; fill the pots three parts full with the compost, making it moderately firm. The seeds should be sown about as thick again as the number of plants required, eventually thinning out the seedlings. Overcrowding should always be strictly avoided.

FRENCH BEANS.—The mild weather we have experienced has made it comparatively easy to keep up the supply of French beans, but now the short and often sunless days are with us it will be a much more difficult task to maintain the supply for the next two or three months. When sowing successional batches use smaller pots than usual—seven-inch pots will be quite large enough. The drainage should be ample, and the soil of a light, open nature. Place the plants as near the glass as possible, and maintain a genial atmosphere, but avoid, as far as possible, the excessive use of artificial heat. Thoroughly syringe the underside of the foliage twice a day, whenever the weather is bright and clear. Plants in bearing should be assisted with alternate waterings of liquid manure and clear tepid water.

FORCING.—Place chervil, mint, and tarragon in heat, also seakale, rhubarb, and chicory at intervals to keep up the supply. Make frequent sowings of mustard and cress.—W. MESSENGER, Woolverstone Park Gardens.

EXHIBITIONS AND MEETINGS.

Cambridge Horticultural Society.

The autumn show of this admirably-managed society, which was founded some ninety years ago, was held on the 6th inst. under most favourable conditions. The weather was bright and genial, and the Corn Exchange contained one of the finest displays of the products belonging to the autumn months that has yet come under our notice this season. We have seen the great building somewhat more crowded than on this occasion, but there was no falling off in the quality of either flowers, fruits, or plants; the cut chrysanthemums were indeed of such outstanding merit that they were fully equal to the best that have been shown this season, and the display of hardy fruits was of quite exceptional excellence.

CHRYSANTHEMUM BLOOMS.

There was a strong competition in the special class open to all England for twenty-four blooms of Japanese varieties, distinct, and the premier award was made in favour of Mr. G. Barker, gardener to Miss Gibson, who surpassed himself on this occasion. The whole of the blooms were of immense proportions, splendidly coloured, finely finished, and well set up. The varieties included: Miss A. E. Roope, Fred Green, R. Fralies, Master James, W. Turner, His Majesty, Frances Jolliffe, W. Parsons, Purity, W. Mease, F. S. Vallis, Mary Farnsworth, Mrs. J. G. Day, Bessie Godfrey, Mrs. G. Drabble, Reginald Vallis, J. H. Salisbury, Thomas Lunt, Dorothy Goldsmith, Mrs. G. C. Kelly, Lady Talbot, and Eclipse. Mr. W. H. Allen was second with an excellent collection of blooms, and Mr. G. Dyson, gardener to W. P. Neal, Esq., Cherry Hinton Hall, was third with blooms that in an ordinary competition would have placed him at the head of the prizewinners. Mr. G. Barker was successful also in the members' class for eighteen blooms of Japanese varieties, staging blooms that were fully equal to those which he contributed to the great open class. Sir J. J. Briscoe, D.L., Bourn Hall, was in fine form on this occasion, as exemplified by the fact that he was awarded premier honours in the class for twelve Japanese, distinct, and also in the classes for six and three varieties. His blooms were of good size, and superb in form and colour. Mr. F. Allen, gardener to Miss Smith, was second for six blooms, and Mr. G. Dyson second for three, both staging remarkably well.

Incurved chrysanthemums were so largely shown as to form a most interesting feature, and the quality was so high as to suggest a revival in the art of exhibiting blooms of this section in their proper form. The chief class was that for eighteen blooms, open to all, and here Mr. G. Barker was first with large, finely-finished, and remarkably fresh blooms of Romance, J. Wynne, Mrs. R. Hankey, Duchess of Fife, Daisy Southam, Buttercup, Miss Cora Stoop, Miss Nellie Threfall, Godfrey's Eclipse, J. W. Higgs, Emblème Poitevin, W. Pascoe, Maritana, Mrs. G. Denyer, Master A. Hall. Mr. T. Todd, gardener to W. A. Briscoe, Esq., Longstowe Hall, was a close second with a superb lot of blooms, the varieties being similar to those represented in the first prize stand. Mr. A .W. Taylor, gardener to Lord Inchcape, had blooms of a high order of merit for third place; they were not, perhaps, quite so deep as could have been desired, and this was accentuated by the low level at which they were staged. Mr. G. Barker scored for twelve incurved with finely-developed blooms, and was closely followed for second place by Mr. G. Dyson, who was first for six and three.

The contributions to the vase classes for incurved and Japanese formed a remarkably fine feature, the entries being numerous, and the blooms splendidly developed. For the awards for six vases of incurved, three blooms in each, there was a very keen contest, and at the head of the numerous competitions was Mr. G. Dyson, whose blooms were of large size and superbly finished, those of Romance and Mrs. J. Wynne being exceptionally meritorious. Mr. G. Barker was a close second with a grand lot of blooms, and Mr. A. W. Taylor was third with flowers evincing cultural skill of a high order. In the corresponding class for six vases of Japanese varieties, three blooms of each, Mr. G. Barker occupied the premier position with exceptionally fine blooms of W. Mease, W. A. Turner, Hon. Mrs. Lopes, Frances Jolliffe, and Mrs. A. E. Roope. Mr. T. Todd and the Rev. C. F. Townley followed closely for second and third places.

As is usual at Cambridge, decorative and single chrysanthemums were staged in large numbers, and the quality of the blooms was higher than in any previous year since they were given a place in the schedule of the society. For six vases of decorative varieties, Mr. A. Lelliott won with bold arrangements of fresh well-coloured flowers, and Mr. J. Hall, who occupied the second place, also staged well, and in the corresponding class for single chrysanthemums he was first with superb flowers. Mr. W. Dobbs, who is highly successful in the cultivation of the varieties belonging to the single section, was second with blooms of much merit. The first prize for pompons in vases was awarded to Sir J. J. Briscoe, who had a beautiful arrangement. There was an especially keen contest for the prizes for three vases of single chrysanthemums, and Mr. W. Dobbs, who occupied the post of honour, was seen at his best. Mr. R. L. Hudson and Sir J. J. Briscoe were second and third with finely-developed flowers. For three vases of single varieties, disbudded, Mr. Todd and Mr. G. Drayson were the most successful exhibitors.

Mr. T. Ward, The Graperies, Bishop's Stortford, exhibited a large and tastefully arranged group of chrysanthemum blooms, which attracted much attention from the visitors. It comprised a dozen or more pyramids, six or seven feet high, of decorative and single varieties, and between them were bowls and vases of specimen blooms in a high state of development. The award of a gold medal was made.

PLANTS.

The competition in the class for groups of chrysanthemum plants was not quite equal to that of last year, and consequently they failed to form so fine a feature as usual. Mr. G. Dyson, who was successful in obtaining premier honours, had a magnificent arrangement, both flowers and foliage of the chrysanthemums being splendidly developed, and the ornamental-leaved plants used in association with them were high in quality and arranged with much taste. The more successful of the competitors in the classes for specimen plants were Mr. G. Dyson, Mr. G. Willers, and the Rev. C. F. Townley. Begonias were finely shown by the exhibitor last named, and Mr. G. Dyson, who also staged large, finely-flowered examples of Salvia splendens.

FRUIT.

Fruit was so largely and well shown as to form a feature remarkable alike for its interest and attractiveness. Apples and pears were shown in sufficient quantities to fill a broad stage extending the whole length of the spacious hall, and the first-named were so rich in colouring as to surpass anything we had previously seen this season. Very keen was the contest in the class for twelve dishes of apples, to comprise equal numbers of culinary and dessert varieties, and in the result the premier award was made in favour of Mr. J. H. Ridgwell, Histon, who had remarkably fine dishes of Warner's King, Newton Wonder, Lord Derby, Mère de Ménage, Peasgood's Nonsuch, Bismarck, Tyler's Kernel, Charles Ross, Cox's Orange Pippin, Gascoigne's Scarlet, Wealthy, and American Mother. Mr. A. Lelliott was second, with Cox's Pomona, Braddick's Nonpariel, Allington Pippin, and Cox's Orange Pippin as his best dishes; Mr. R. Stevenson, third. Even more keen was the competition for the prizes for six dishes of apples, containing equal numbers of culinary and dessert varieties. Mr. Todd won first prize with Cox's Pomona, Gascoigne's Scarlet, and Rival as his dessert varieties, and Hoary Morning (very fine), Lord Derby, and Peasgood's Nonsuch as his culinary varieties. Mr. J. H. Ridgwell was an uncomfortably close second, and Mr. W. P. Hollis third.

For two dishes of dessert apples, Mr. R. Stevenson and Mr. J. H. Ridgwell were first and second; and in the class for three dishes of culinary apples the first and second prizes were awarded to Mr. Todd and Mr. J. H. Ridgwell. The best dish of Wellington was shown by Mr. W. P. Hollis; the best dish of Lane's Prince Albert by Mr. S. W. Cole; the best dish of Peasgood's Nonsuch by Mr. Todd; and the best dish of any other culinary variety by Mr. R. Stevenson, who had grand fruit of Bramley's Seedling. Messrs. R. M. Jones and Sons had the best dish of Cox's Orange Pippin; Mr. A. Lelliott was successful in taking the premier award for a dish of King of the Pippins; Mr. R. Stevenson won the first prize for the best dish of Blenheim Pippin of dessert size; Mr. Todd won for a dish of Ribston Pippin; and Mr. A. Lelliott obtained premier honours for any other dessert variety with Allington Pippin. The special prize for the best dish of apples in the foregoing classes was awarded to Mr. S. W. Cole for the magnificent fruit of Lane's Prince Albert exhibited by him in the class specially provided for that variety.

Baskets of apples constituted, as usual, an interesting feature, as in each class the entries were numerous, and the fruit highly meritorious. In each class the weight of fruit required was 20lb., and in that for dessert varieties Mr. R. Stevenson, Mr. A. Lelliott, and Mr. J. H. Ridgwell were the prize-takers in the order of their names, each staging Cox's Orange Pippin of high quality. In the corresponding class for culinary apples Mr. S. W. Cole was first with grand fruit of Newton Wonder. Mr. A. Lelliott followed closely with Lane's Prince Albert of high quality; and Mr. J. H. Ridgwell, third, with Lord Derby at its best.

The large array of finely-developed fruit of dessert and culinary pears suggested a season of plenty rather than one of great scarcity, and proved a veritable surprise to those who are well acquainted with the present position of the supplies of choice pears of home growth. Mr. Todd was successful in occupying the first place in the class for six dishes, with exceptionally fine fruits of Durondeau, Buerre Superfin, Marie Louise, Le Lectieur, Doyenné du Comice, and Pitmaston Duchess. Mr. W. Dobbs was a close second with remarkably fine fruit, especially noteworthy being the dish of Emilie d'Heyst. For three dishes Mr. Dyson and Dr. Dalton were first and second. Mr. Dyson was first for a dish of Doyenné du Comice; and Mr. Todd won in the class for a dish of Pitmaston Duchess.

Grapes were hardly up to the high average that usually obtains at Cambridge. Sir J. J. Briscoe obtained premier honours for two clusters of Muscat of Alexandria, and Mr. Dyson followed for second place. The best two bunches of Alicante were shown by Mr. R. L. Hudson, and in the class for any other black variety the exhibitor last-named was first with Gros Maroc, and Mr. Dyson second with Lady Downe's Seedling.

VEGETABLES.

Several classes for collections of vegetables were provided, and all were admirably filled. Mr. A. Lelliott was successful in obtaining first place in the society's class for ten kinds, with excellent produce, potatoes, celery, cauliflowers, and Brussels sprouts being particularly good. Mr. P. Hawkes was a close second, and in Messrs. Sutton and Sons' class for six kinds he occupied the post of honour, in both cases staging meritorious produce. The Rev. F. C. Townley and Mr. R. L. Hudson were the most successful competitors in Messrs. E. Webb and Sons' class for six kinds. Lord Inchcape scored for twelve dishes of potatoes with medium-sized, shapely tubers of well-known variety. For six dishes, Mr. Todd was a capital first with Mr. Bersec, Snowdrop, The Admiral, Table Talk, and Twentieth Century at their best. As usual, the whole of the arrangements were remarkable for their completeness, and reflected much credit upon the administrative ability of Mr. Rupert Fuller, the hon. secretary, and other members of the executive.

Portsmouth.

OCTOBER 29, 30, and 31.

The annual exhibition of this society was held in the Town Hall, and was doubly a success, both horticulturally and financially. Groups of chrysanthemums in pots, both single and double, were numerous, and of a high order of merit. Cut blooms were exceptionally fine, especially the incurved and single varieties, the latter standing out prominently. The arrangements were quite good, under the careful guidance of Mr. W. E. Gill, hon. secretary.

CUT BLOOMS OPEN TO ALL.

The leading class was for thirty-six Japanese, in not less than eighteen varieties, for which a silver cup, value £20, and £5 in cash, were offered. Four competed, making a bold display. Mr. Baxter, gardener to Captain Dalgety, Lockerly Hall, Romsey, was easily first with large blooms, fully developed and of rich colour. The leading varieties were Lady Talbot, Master James, F. S. Vallis, Mrs. Stevenson, Frances Joliffe, Mrs. G. Drabble, Queen Mary, Bob Pulling, the Hon. Mrs. Lopes, Mary Farnworth, John Peed, His Majesty, and Mrs. Luxford. Mr. G. Hunt, gardener to Pantia Ralli, Esq., Ashtead Park, Epsom, was a good second with smaller blooms; Mrs. Lloyd Wigge, Mrs. H. J. Jones, and Master James were his more prominent flowers. Mr. Herbert, gardener to Sir F. Fitzwygram, Leigh Park, Havant, third. Mr. Hunt secured the leading place for two dozen Japanese, with an even set of blooms of high quality; Frances Rowe, His Majesty, Miss Boyes, and Frances Jolliffe were the most noteworthy among so many superior blooms. Mr. D. Edwards, gardener to W. Garton, Esq., Sarisbury Court, Southampton, was a close second amongst four entrants. Mr. Herbert third; the last-named won for a dozen distinct Japanese.

Incurved blooms were remarkable, being large and especially well finished. For twelve, four entered, the best coming from Mr. Edwards, several of them measuring six inches in diameter; Mrs. J. C. Bryce, Mrs. Percy Wiseman, Godfrey's Eclipse, Mrs. G. Denyer, W. H. Thorp, and Miss Annie Holden were outstanding varieties. Mr. Hunt second, with neat smaller blooms. Single-flowered varieties were staged numerously. For six blooms, of distinct varieties, seven competed. Mr. Herbert, with a remarkable set, won the premier position; Mensa was remarkably fine; Edith Taylor, Draco, and Metta with Bronze and Edith Pagram, were also desirable. Mr. Edwards, with grand flowers of Silvi Slade and Mensa, won the second place.

Local classes were numerous and well filled. Mr. White, 6, Garden Terrace, Southsea, won easily with desirable blooms. Mr. Johnson, 10, Garnier Street, Southsea, second. Pompons were a distinct feature here, so seldom are they seen nowadays. For twelve sprays, Mr. H. Snooks, 5, Fitzroy Terrace, Fratton, was first, as he has been many years in this class, staging high quality, medium-sized blooms of W. Kennedy. W. Westlake, Acto, Eclipse, Fermy, and Mrs. Astic were the best. Mr. G. Johnson, 5, Clydesdale Terrace, Southsea, second. Five competed for six sprays of single-flowered varieties. Mr. H. Snook led with blooms but little less meritorious than in the open class. Anemone-flowered varieties are now seldom seen, but, when they are in good order, deserve noting. Mr. Snook, with medium-sized, fresh blooms with fair centres, was first, Mr. W. Snook following.

PLANTS.

A silver cup was offered for a group of chrysanthemums in a superficial area of 60 square feet. There were five entries, and the several groups made a fine display, extending the length of one side of the hall. Mr. W. E. Gill, Osborne Road, Southsea, the hon. secretary, was an easy first with an excellent exhibit of dwarf-grown plants, well furnished with good leaves and high-class blooms, not in the least crowded. Mr. W. B. Jeffreys, 37, Clarence Parade, Southsea, a good second, with finely-developed blooms on taller plants; Mr. W. Abbot, Twyford Avenue, Portsmouth, third. Single-flowered varieties made an excellent display, four groups were arranged for the gold medal offered. Mr. Burridge, North End, Portsmouth, was first with freely-flowered plants carrying good blooms; Mr. J. Johnson second with a tasteful arrangement of smaller blooms; Mr. W. E. Gill third. Mr. C. White had the best twelve specimens, the plants carrying good blooms. The Portsmouth Parks Committee were second for a group, and first for twelve specimens.

TABLE DECORATIONS.

Ladies' table decorations were of an interesting character. Mrs. Rapley, Warblington Cottage, Havant, won easily with bronze and yellow single chrysanthemums, nicely displayed, with suitable greenery in low vases, and a thinly-arranged centrepiece. Miss L. Hawkes, 325, Lake Road, Portsmouth, second with an arrangement in bronze chrysanthemums.

NON-COMPETITIVE.

Trade exhibits were not numerous, but interesting. Messrs. W. Wells and Co., Merstham, Surrey, had an interesting collection of chrysanthemums—Wm. Vert, Mrs. K. Luxford, Queen Mary, and the new Daily Mail Japanese. Amongst singles, Coronation, lilac rose, with silver tips; Marjorie Lloyd, amber bronze; Eric Wilde, rose; and Mdme. T. H. Morel, yellow, were noteworthy. The Barnham Nursery Company had four dozen dishes of apples of superior quality, and Newton Wonder, Rival, Charles Ross, Lord Derby, Allington Pippin, Chelmsford Wonder, and King of Pippins were the most conspicuous.

West of England Chrysanthemum Society.

This society opened its annual show in the Guildhall, Plymouth, on November 4. The entries were more numerous than they have ever been before, and the exhibition was by far the best ever held under the society's auspices, and marks a distinct advance on previous years.

In the class for thirty-six Japanese blooms, first prize was won by Sir Randolf Baker (gardener, Mr. Usher), Ranston, Blandford, with a marvellously perfect stand of very large blooms, better than any ever seen here before; Hon. Mrs. Lopes, F. S. Vallis, His Majesty, Rose Pockett, Mrs. G. Drabble, and Francis Rowe were exceptionally fine. For eighteen Japanese blooms Sir R. Baker led, and his Mrs. G. J. Beer, W. Turner, G. Lock, and Lady F. Ryder were extremely good. Twelve vases single chrysanthemums found Mr. Vere Cholmondley first, and his Mrs. W. Buckingham, Sylvia Slade, and Ceddie Mason were very pretty. For three vases single chrysanthemums, white, first prize went to Mr. T. B. Bradshaw; three vases, single, yellow, first prize, Mr. Vere Cholmondley; three vases, single, any other colour, first prize, Mr. Vere Cholmondley.

For a group of stove and greenhouse plants, Mr. J. Webber scored with Lilium longiflorum, carnations, cyclamen, Begonia Gloire de Lorraine, Erica gracilis, E. melanthera, crotons, odontoglossums, cypripediums, and bamboos, with a tall palm in the centre. For a table decoration there were eleven entries, and the first prize was won by Mrs. W. Liddle with a beautifully-arranged table of the salmon-pink rose Madame Abel Chatenay.

For a collection of salads one of the prettiest exhibits in the whole show was staged, the scarlet and yellow capsicums and tomatoes having a brilliant effect. The stand contained yellow, red, and black capsicums, Australian cress, American cress, Tom Thumb lettuce, cos lettuce, cucumber, watercress, variegated chicory, celery, beetroot, Batavian endive, curled endive, chives, radishes, red and white. At the back of the stand were two pillars about three feet high hung with scarlet and yellow capsicums and currant tomatoes, red and yellow, and in front were two pillars of mustard. The effect of the whole was most attractive, and was admired by numbers of visitors. The prize was won by Mrs. R. Bainbridge.

The first prize for a group of single chrysanthemums was won by Mrs. R. Bainbridge with a very tastefully-arranged collection of fresh flowers, with a spreading bamboo in the centre. For four specimens Japanese chrysanthemums, Mr. E. J. Hannaford was first, and for one specimen Japanese chrysanthemum Mr. W. J. Ellis led. In the other classes the chief prize-winners were—for six primulas, Mr. G. Shellabear; six Primula stellata, Mr. G. Shellabear; six pelargoniums, Mrs. R. Bainbridge; six begonias, white Gloire de Lorraine, Mrs. R. Bainbridge; six begonias, any variety, Sir R. Pole Carew; six stove or greenhouse table plants, the Earl of Morley.

In the classes confined to residents within fifteen miles of Plymouth, the silver challenge cup for twelve Japanese blooms was won by Mr. W. J. Ellis; twenty-four Japanese blooms, Lady Buller; six Japanese blooms, Mr. C. E. Curtis.

In the fruit classes, first prize for twenty dishes was won by Mr. H. St. Maur, and first for twenty dishes of apples was awarded to the Earl of Morley. A fruit of Lord Derby apple was shown by Miss Hawker, which had a circumference of 17¾ inches, and weighed 30oz., and a specimen of Mère de Ménage, with a circumference of 16½ inches and weighing 28oz. was shown by Mr. J. A. Paley. The vegetables were very good, and some splendid collections were shown. First prize for black grapes was won by Mr. H. St. Maur, and first prize for white grapes by Mr. F. R. Rodd.

The nurserymen's exhibits did much to enhance the attractions of the show. The Devon Rosery, Torquay, showed a marvellously perfect selection of fruit, which was awarded a gold medal. There were a hundred dishes of apples and several of pears, and fine bunches of Black Alicante, Barbarossa, Lady Hutt, and Gros Colmar grapes. Among the apples some of the most attractive were Bramley's Seedling, very highly coloured; The Queen, very fine; Belle de Pontoise, Peasgood's Nonsuch, large in size; Gascoigne's Scarlet, very brilliant; Cox's Orange Pippin, Bismarck, Lord Derby, Golden Noble, American Mother, Wealthy, and Mère de Ménage, while of pears there were, amongst others, Catillac, Bellisime d'Hiver, Beurre Bachelier, Duchesse d'Angoulême, and Verulam, and there were also baskets of medlars.

Messrs. Robert Veitch and Son, Exeter, exhibited an interesting stand containing Cypripedium Leeanum, C. L. superbum, C. insigne Maulei, C. i. Sanderæ, C. i. punctatum violaceum, Nerine Bowdeni, Berberis nepalensis, B. Thunbergi, Gloriosa superba, Skimmea japonica, Ceanothus Gloire de Versailles, Physalis Bunyardi, Mutisia decurrens, Pernettyas, Pancratium macrostephana, Cyclamen persicum, Schizostylis

coccinea, Veronica Veitchi, violets in variety, and about two dozen varieties of winter-flowering carnations. Messrs. Webber and Sons showed a large group of carnations.

Manchester Chrysanthemum Show.

NOVEMBER 11 and 12.

The Royal Botanical and Horticultural Society of Manchester held an autumn show in the Town Hall on the above dates, and a more charming display of autumn flowers could not well have been desired. The lovely hall was well furnished, and the splendidly developed plants and blooms gave a charming glow of colour in which yellow predominated.

For nine pots of large-flowered varieties, Mr. P. Seddall, gardener to E. Breslauer, Esq., was the first, with plants of medium size, carrying from twenty to thirty good flowers, all of which were bright and fresh. For six plants of Japanese varieties, Mr. Seddall was again first with well-flowered and remarkably bright specimens.

In the class for displays in which the competition was limited to nurserymen, Mr. W. J. Garner secured the premier award for a bold and telling arrangement on the organ platform. It included grand specimen palms, which made a splendid foil to the pillars of chrysanthemums which were tastefully arranged and interspersed with ferns and vases of bloom.

The chrysanthemum blooms were all staged on boards, and for twenty-four incurved, in not less than 12 varieties, Mr. C. Goves, gardener to Sir Gilbert Grenall, Bart., was first with a stand of blooms superbly developed, the chief being Mrs. G. Denyer, Clara Wells, Marjorie Shields, Romance, and Yellow Hygate. For twelve incurved, Mr. J. Stoney, gardener to Lieut.-Colonel J. B. Gaskell, was first, followed by Mr. G. Corbett, gardener to C. Lamb, Esq., for second place. In competition for the prizes for thirty-six Japanese, in not less than eighteen varieties, Mr. Charles Jones obtained premier honours with a telling lot of blooms, the best being Frances Joliffe, Lady Talbot, F. S. Vallis, and Mary Farnworth. For eight Japanese, Mr. C. Goves was first with a remarkably fine stand, his blooms being excellent throughout. Especially noteworthy were those of F. S. Vallis, W. Turner, and W. Mease; Mr. C. Jones second, and Mr. G. Corbett third. In the class for twelve Japanese, Mr. Corbett took the lead, with Mr. H. Phillips, gardener to C. W. Pritchard, Esq., second. In competition for the prizes for thirty-six blooms, miscellaneous varieties, Mr. J. Storey was first with an excellent collection, and put up a fine stand in which the blooms of reflexed and anemone varieties were of special interest as reminders of kinds that are now seldom seen; Mr. J. Roberts, gardener to Miss Lightfoot, was a capital second.

In the great class for forty-eight blooms, twenty-four Japanese and twenty-four incurved varieties, Mr. C. Goves was the only exhibitor, but his blooms were of high quality throughout, and the premier award was deservedly made in his favour; especially good were Bob Pulling, Leigh Park, Rival, Hon. Mrs. Lopes, Purity, etc.; incurved—Pantia Ralli, Mrs. B. Hankey, G. F. Evans, Calypso, Romance, etc. For twenty-four blooms, twelve Japanese and twelve incurves, Mr. S. Olliver led, with Mr. J. Stoney second. In the local classes Mr. F. Phillips gardener to J. W. Pritchard, Esq., was the most successful for Japanese blooms, and Mr. S. Olliver with the incurved.

In competition for the prizes for the most tastefully decorated dinner table, Messrs. J. Nixon, H. B. Vernon, and W. J. Garner were placed as named, the two former utilising orchids, and the latter roses. For one basket, Messrs. W. J. Garner, H. B. Vernon, and J. Nixon were the successful exhibitors. The class for three bouquets contained a charming display; Mr. W. J. Garner held the coveted position with carnations, Messrs. T. Nixon and A. Porter being second and third.

MISCELLANEOUS PLANTS.

The class for six pots of Roman hyacinths proved a strong one. The prizewinners were Messrs. R. Burch, gardener to C. H. Procter, Esq., A. R. Jones, and T. Petrocochina. For eight primulas the awards went to Messrs. W. Bramwell, T. Kenyon, and T. Petrocochina; for six cyclamens, to Mr. Bramwell and Mr. M. Woollard, gardener to Mrs. Gill; and for six winter-flowering begonias to Messrs. W. Woollard, C. F. Bostick, and T. Petrocochina.

In the class for a collection of orchids, amateurs, Mr. J. Brown, gardener to S. Greatrix, Esq., secured the leading award with cattleyas, cypripediums, odontoglossums, and others, well arranged.

In the trade class for a collection of orchids, Messrs. Charlesworth and Co. received a Gold Medal for a group in which fine forms of Vanda cœrulea, Cattleya Fabia alba, and Odontoglossum crispum in variety were noteworthy. Messrs. J. Cypher and Sons also received a Gold Medal for a meritorious display, in which Cattleya labiata, C. Walkeriana, C. callistoglosa, with oncidiums and cypripediums, were conspicuous. Mr. A. J. A. Bruce was awarded a Gold Medal for a charming group of sarracenias arranged with palms, ferns, etc. Messrs. Dickson and Robinson received a silver-gilt Medal for a large table of cut chrysanthemums and Michaelmas daisies well set up.

The arrangements, as usual, were in the able hands of Mr. P. Weathers, the society's secretary.

Reading Gardeners' Association.

The usual fortnightly meeting was held in the Abbey Hall, by kind permission of Messrs. Sutton and Sons, on Monday, October 27, when, owing to the enforced absence of the President, through indisposition, and of the Chairman (Mr. Powell), in consequence of the serious illness of Mrs. Noble, Mr. J. T. Tubb (Vice-chairman) presided over a good attendance of members.

The lecturer for the evening was A. Harrison, Esq., of Watford (late of Oneglia, Italy), and his subject was "Orchids."

The Lecturer first pointed out, by the aid of lantern slides, the structural peculiarities of the flowers of orchids and their resemblance to many insects, such as moths, butterflies, etc.

The extraordinary form of the reproductive organs, and the means whereby insects were attracted and used for the purpose of pollination and intercrossing, were also shown by slides of coryanthes, stanhopea, etc.

Mr. Harrison then went on with plates and descriptions together, giving cultural details of the most useful species, such as might be grown successfully in warm, intermediate, or cool greenhouses in the company of ordinary plants usually found in such structures, provided a few essential details were observed. He emphasised the importance of the use of rain water only, as well as of careful ventilation, stating that, while movement of air was absolutely necessary, nearly all the species objected to draughts. Most of the air admitted should come through ventilators below the stages and not at the stage level. It was pointed out how excess of ventilation at the apex of a house dissipated the moisture and unduly dried the atmosphere, to the detriment of the plants.

Among the species for warmer houses, of which slides were shown, Mr. Harrison included Cattleyas Mendelli Trianæ, labiata, Gaskelliana, gigas, Hardyana, and aurea; Lælia purpurata, Dendrobiums nobile, crassinode, Wardianum; Cypripediums Leeanum, Charlesworthi, bellatum, callosum Sanderæ, Curtisi. Plates were also shown of some of the newer and beautiful compound hybrids, such as lælio-cattleyas, odontiodas, brasso-cattleyas, and brasso-lælias, and the lecturer stated that the great vigour of many of these hybrids made them more amenable to cultivation than a number of the species, but added that the prices of many were prohibitive.

Among species needing cool treatment plates of Odontoglossum crispum, in many varieties were shown, O. Halli, O. Harryanum, as well as many hybrid odontoglossums and Cypripedium insigne. Seedling cypripediums were also shown growing on the compost of an established plant, and the various methods of raising orchid seedlings described.

At the conclusion of his remarks, Mr. Harrison answered numerous questions put to him by members of the audience, and, at the close of the meeting, was accorded a most hearty vote of thanks.

The hall presented an exceedingly bright and gay appearance, as, apart from specimen orchids brought by the lecturer, there were no fewer than eight exhibits. Mr. G. Tovey, The Gardens, Leighton Park School, staged 18 dishes of apples of much merit, and was awarded a Certificate of Cultural Merit. They were also judged for the points competition. For the latter three fine collections of chrysanthemums were put up, the exhibitors being Mr. J. T. Tubb, The Gardens, Bearwood; Mr. H. Reeves, The Gardens, Blandford Lodge, and Mr. H. G. Cox. Mr. E. Blackwell, head gardener to the Lord Chief Justice, staged a collection of well-grown apples, and Mr. H. Goodyer, The Gardens, Stoneham House, three baskets of fine Sutton's Ailsa Craig onions, which secured almost the maximum number of points. From the University College Gardens, Mr. Drew sent beautiful cut chrysanthemums. and Mr. W. Lees exhibited a group of seedling fuchsias.

Two new members were elected.

The Hon. Secretary acknowledges with thanks the receipt from "Onlooker" of two five-pound notes, to be devoted to special objects. The committee will consider and endeavour to carry out the donor's wish.

Surbiton, Kingston, and the Dittons.

The ninth annual exhibition of this society was held in the Assembly Rooms, Surbiton, on the 4th and 5th inst. Favoured with ideal weather, the show was a record one as regards entries, and the quality and number of blooms staged, while the public support accorded the society was one of the marked features of the day, and seemed a fitting reward to the strenuous efforts that have been made, especially by Mr. T. A. Hill, the secretary.

The most popular class in the show was the one for twelve blooms, Japanese, shown in four vases, in which Mr. H. C. Gardner, gardener to Lord Foley, Ruxley Lodge, Claygate, took first place; this exhibit also provided the premier bloom, this being a faultless specimen of W. Turner. Amateurs made a brave show, even against their professional brethren. The challenge cup offered to amateurs for two vases of Japanese blooms, five in each, was won, for the third year in succession, by Mr. J. Surry, of Oakdene, St. George's Road, Norbiton, with a splendid exhibit, and particularly fine were his blooms of Queen Mary and Lady Talbot. The cup now becomes Mr. Surry's absolute property.

The "Coronation" silver cup, given by Mr. T. Salter Cox, vice-president of the society, for the best group of chrysanthemums in pots, as grown, was awarded to the Marquis of Ripon, Coombe Court, Kingston Hill (gardener, Mr. T. Smith), who thereby displaces Mr. A. Zimmern, Oak Hill Drive, Surbiton (gardener, Mr. A. Corps), who has held the trophy for the past two years. The first prize group was composed of fresh, well-balanced flowers, among which Amber Queen, Miss Olive Millar, Mrs. G. Drabble, His Majesty, R. Vallis, Eclipse, and Lady Talbot stood out prominently; Mr. A. Zimmern had a well-balanced group of dwarf, well-grown plants; third place fell to Baron O. E. von Ernsthausen, Manor House, Ditton Hill (gardener, Mr. G. James), whose group comprised decorative singles, with a few Japanese blooms.

For a group of flowering and foliage plants in pots, first place fell to Mr. C. Burford (gardener to Mrs. Windeler), Ditton Hill,

those taste of arrangement was well sustained; second, Mr. E. Barber, gardener to Fownes Rigden, Esq., Brentor, Surbiton Hill, who also staged a light and attractive group.

In the open class for twelve blooms of Japanese, in four varieties, the first prize was given by H.R.H. the Duchess of Albany. Mr. H. C. Gardner scored with a heavy set of finely-finished blooms, that comprised Lady Talbot, W. Turner, F. S. Vallis, and Frances Joliffe, and, as already noted, this exhibitor supplied the premier bloom in the show; second place fell to Mr. S. Read, gardener to R. S. Bond, Esq., Surbiton Hill; and third prize was awarded to Mr. W. Jinks, gardener to G. Hartmann, Esq., Newlands, Thames Ditton; and Mr. T. Smith brought up the rear. For eighteen Japanese, not less than 12 varieties, a local class, first place went to Mr. W. Jinks with a bright set; his best blooms included H. E. Converse, Edith Jameson, Miss A. Nicolls, Kara Dow, W. Mease, Rockett's Crimson, etc.; second prize fell to Mr. S. Pead; and Mr. H. C. Gardner was third.

For twelve Japanese, distinct, Mr. T. Smith won; Mr. C. Burfoot was placed second; and Mr. Mercer, gardener to H. J. Marsh, Esq., Oakfield, Surbiton Hill, third. For six Japanese, distinct, E. Goddard, Esq., Coombe Brook, Kingston Hill (gardener, Mr. W. Coldicott), was placed first; Mr. W. Cundall, The Wood, Oak Hill, Surbiton Hill, coming second. For six incurved blooms, Messrs. W. Jinks, S. Pead, and F. Dalton, gardeners to the Earl of Dunraven, Kenry House, Kingston Hill, gained awards in the order named.

The single vase classes of five blooms were well filled, and Mr. W. Jinks came first for whites, with Mrs. G. Drabble and Miss A. Nicholls; Mrs. Gardner second; and Mr. Pead third, with W. Turner; and Mrs. G. Drabble respectively. For five yellow blooms, Mr. Gardner took first place with massive blooms of F. O. Fallis; Mr. Pead second with Lady Talbot; and Mr. H. Jinks third with the same variety. For five blooms, any colour, white and yellow excluded, Mr. Pead staged a lovely set of Francis Rowe; Mr. T. Smith second, with W. Mease and Master David; Mr. Gardner third, with nice clean flowers of Alice Lemon.

The class for six vases of singles—disbudded—brought out eight entries, the honours being shored by Messrs. W. Jinks, H. C. Gardner, and S. Pead. A similar number entered in the class for singles grown in natural sprays, and here Messrs. T. Smith, H. C. Gardner, and C. Burfoot were successful. For a basket of chrysanthemums, arranged, Mr. C. Burfoot was awarded first place amongst five competitors.

Mr. J. S. Kelly, gardener to H.R.H. the Duchess of Albany, Claremont, Esher, took first place for primulas, solanums, apples, pears, and vegetables; Mr. Gardner scored for grapes; and Mr. Mercer for six winter-flowering begonias; and in the single-handed gardeners' section this exhibitor came out first in both classes. The amateurs' class for ten Japanese blooms, not less than five varieties, to be shown in two vases, fell to Mr. F. J. Surry, Oakdene, St. George's Road, Norbiton, who, having won the cup for the third time, now becomes absolute owner; Mr. E. Nildman, Gordon Avenue, St. Margaret's, second; and Mr. G. Moorman, Hampton Court, third. Other successful amateurs included Mr. C. Hawkins, Wyndham Road, Kingston-on-Thames; Mr. L. Hobbs, Thames Ditton; and Mr. J. Woods, Surbiton Council Offices.

Mr. Burfoot scored for table decoration, and Mrs. T. Smith was placed first for a table centrepiece.

In the vegetable classes, Messrs. Plowman, Mercer, W. H. Hawkes, A. Corps, and T. Brill shared the honours.

The competitive section being so well filled this year, only a limited space could be allotted to non-competitive exhibits. Mr. James Naylor, of Hampton Court, tastefully decorated the front of the stage with magnificent specimens of Begonia Gloire de Lorraine, grouped with chrysanthemums and foliage plants. Mr. L. Russell, Richmond, staged a collection of trained ivies and berried shrubs. A capital display of some thirty-six dishes of apples came from Lord Foley, Ruxley Lodge.

Birmingham Chrysanthemum and Fruit Show.

(Continued from page 858.)

Mr. Sheppard, Selly Park, had the best two bunches of Muscat of Alexandria; Mr. M. West, gardener to Lester Lea, Esq., Greenhill House, Moseley, being second. Dishes of apples and pears were numerous and of good quality throughout, Mr. Robt. Price, Birmingham, being successful in several classes, together with the exhibitors whose names we have already mentioned.

VEGETABLES.

The classes for vegetables were, as usual, largely composed of those for which various seedsmen offered the prizes. They occupied the whole of the large bay at the end of the hall, and were of fine quality throughout.

In Messrs. Webb and Sons' class for a collection of eight varieties, there was a strong entry, the first prize winner being Mr. Fred. Barratt, Overton. He had magnificent leeks, parsnips, onions, celery, and cauliflowers, with carrots, sprouts, and potatoes of good quality. Second prize was awarded Mr. Jones, Ruabon, who was very strong in onions and leeks; third prize going to Mr. H. Keep, Aldermaston, Berks.

In Messrs. Sutton and Sons' class the premier award went to the credit of Mr. E. Beckett, gardener to Right Hon. Vicary Gibbs, Aldenham House, Elstree, who showed splendid examples of Sutton's Prizetaker leeks, Student parsnip, Ailsa Craig onion, New Red Intermediate carrot, Supreme potato, A1 tomato, and Dwarf Gem sprouts. The second prize in this class went to Mr. J. Hudson, Leicester; Mr. E. R. Janes being placed third. Robert Sydenham Limited, Tenby Street, Birmingham, as usual, provided a number of classes for produce grown from their seeds, and the exhibits entered occupied a stage the whole width of the spacious hall. In the collection of nine kinds there were four entries, the principal prize going to Mr. Edward Deakin, Hay Mills, Birmingham. The vegetables in this collection were well-grown samples of The Lyon leek, Standard Bearer celery, St. Valery carrot, Excelsior onion, Hollow Crown parsnip, Ideal tomato, Wroxton sprout, Up-to-Date potato, and Autumn Giant cauliflower. Second prize went to Mr. T. Griffiths, Somerset Road, Handsworth; and third to Mr. F. Anderson, Moseley. The single dish classes for vegetables were very fine, and it is only want of space that prevents detailed accounts of them all. There were many exhibits that might well have been described in length, so great was their quality.

NON-COMPETITIVE.

As usual, the non-competitive exhibits were an important and most attractive portion of the show, and from all points of view were a most important part of the exhibition.

Messrs. Godfrey and Son, Exmouth, Devon, showed Molly Godfrey, Snow Queen, Excelsior, Godfrey's Perfection, Lily Mann, and Devonshire Lass among other good single chrysanthemums, and a fine lot of large-flowered Japanese varieties, among which Autocrat (rosy-amaranth), and Godfrey's Success (bright yellow) were very distinct and good. Messrs. W. Wells and Sons, Merstham, had a fine exhibit of big blooms, Queen Mary, Daily Mail, Mrs. Gilbert Drabble, and James Fraser, a new, long-petalled yellow, after the style of F. S. Vallis, being their most outstanding varieties. Another good display of both single and double chrysanthemums was made by Mr. H. Woolman, Birmingham, the tall vases of flowers being interspersed with silver-leaved centaureas and small acers.

The Studley Horticultural College were exhibitors of perpetual-flowering carnations, and also of grapes, the carnations being daintily displayed in glass vases with Asparagus plumosus as a setting. Mr. H. N. Ellison, West Bromwich, arranged greenhouse ferns in his usual good style. Choice adiantums, graceful davallias, and finely-cut nephrolepis were used with good effect. Messrs. W. H. Simpson and Sons, Birmingham, had an extensive display of antirrhinums, which were remarkably fine for this season of the year, the colours being clean and bright. Another very creditable exhibit for so late in the year was a fine group of pæony-flowered and decorative dahlias shown by Messrs. Piper and Sons, Bayswater, London. Messrs. R. J. Barnes and Son, Wyche, Malvern, had some exceedingly well grown single and decorative chrysanthemums, which were large, fine flowers of decisive and useful colours.

Mr. E. R. Janes, gardener to the Right Hon. Lord North, Wroxton Abbey, Banbury, made a splendid show of onions. The varie-

By Special Appointment to His Majesty the King.

MESSRS. JAMES VEITCH & SONS, LTD.

Royal Exotic Nursery, CHELSEA.

Beg to announce that they are still carrying on every branch of their NURSERY BUSINESS for the supply of plants, trees, shrubs, vines, and fruit trees, etc., at their Chelsea, Coombe Wood, Langley, and Feltham Nurseries.

ties included Sutton's Selected Ailsa Craig, Cranston's Excelsior, Danver's Yellow, The Lordkeeper, and The Wroxton, besides several dishes of smaller varieties, such as Paris Silver Skin, Crimson Globe, and Blood Red. Mr. Janes is to be complimented on putting up one of the finest displays of onions we have ever had the pleasure of seeing. A big stand of vegetables, with several groups of flowering plants, came from Messrs. E. Webb and Sons, Wordsley. Begonias Gloire de Lorraine and Turnford Hall were well flowered, and Saintpaulia ionantha provided a fine dish of rich purple. Single chrysanthemums in vases and some small foliage plants completed the decorations, whilst the vegetables were varied and of good quality. Messrs. Clibrans, Altrincham, specialised in winter-flowering begonias, Scarlet Beauty, an intensely brilliant flower, and Altrincham Pink being two very decorative plants. Miss S. Thompson, Alfred Road, Handsworth, brought an interesting collection of succulent plants, some of the mammillarias, opuntias, and echeverias being good specimens; and there were also a variety of tiny plants in thimble-pots which looked very healthy.

A very elaborate exhibit of vegetables was arranged by Messrs. Toogood and Sons, Southampton, who adopted a pure white background and stage, a covering that set off the well-grown examples of onions, gourds, celery, beet, and potatoes to great advantage. Onions formed the chief feature of Messrs. Dickson and Robinson's exhibit, the well-known Premier being represented by shapely bulbs of upwards of two pounds weight.

The King's Acre Nurseries, Lim., Hereford, showed a grand lot of fruit, which was set up attractively in flat baskets. A model of the giant apple, which recently realised sixteen guineas at Covent Garden, was on view, and proved a centre of attraction. A choice collection of apples was sent by Messrs. H. Cannell and Sons, Eynsford, Kent. The fruit was beautifully coloured, and included such good dessert varieties as Allington Pippin, Rival, Cox's Orange Pippin, and Colville Rouge Precoce. Culinary varieties were also well represented, and a few dishes of good pears completed a fine exhibit. Messrs. J. H. White and Co., Worcester, were exhibitors of fruit, and they had also vases of chrysanthemums, and a flower of Strelitzia Regina, which attracted a good deal of attention.

Messrs. J. Peed and Sons, Norwood, S.E., put up single-flowered chrysanthemums, which included a new yellow of great promise named Sam Alcock. Stuart Smith, a pure white, and Marguerite de Quincey, lilac rose, were other good ones. A large group of hollies, conifers, and ornamental shrubs came from Messrs. John Waterer and Sons, Lim., Bagshot. Ilex crenata aurea, with tiny foliage, I. regina nigra, and I. ferex argentea, the silver Hedge Hog Holly, were but a few of the many good forms shown, some of the tall standard hollies being splendid specimens. Messrs. Robert Sydenham Limited, Tenby Street, Birmingham, arranged single chrysanthemums in their rustic receptacles, making a pretty display, which afforded another demonstration of the usefulness of the well-known table ware. Messrs. Hewitt and Co., Solihull, showed ornamental conifers of shapely growth, and choice quality. A few standards of golden privet relieved the more sombre shades of cupressus, abies, thiyas, etc. A rock and water garden exhibit from the Lapworth Nurseries, Lapworth, Warwick, included a good many flowering plants, such as Viola gracilis, Gentiana acaulis, Potentilla rosea, and a few ericas, whilst small bamboos, acers, and conifers furnished the more prominent parts of a nicely devised exhibit.

Gold Medals.—To Messrs. J. Waterer and Sons, Lim., Messrs. Clibrans, The King's Acre Nurseries, Lim., Mr. E. N. Janes, Mesrs. Pipers, and Messrs. Cannell and Sons.

Silver-gilt.—To Messrs. Godfrey and Sons, Messrs. W. Wells and Sons, Mr. H. Woolner, Messrs. Hewitt and Co., and Messrs. W. H. Simpson and Sons.

Silver.—To Mr. H. N. Ellison, The Studley Horticultural College, Miss S. Thompson, The Lapworth Nurseries, Messrs. J. H. White and Co., and Messrs. Dickson and Robinson.

Bronze.—To Messrs. J. Peed and Sons and Messrs. R. J. Barnes and Son.

Dumfries and Galloway Gardeners' Association.

Mr. A. Hosking, of the Glasgow and West of Scotland College of Agriculture, delivered a lecture under the auspices of this association in the Wesley Hall, Dumfries, on the evening of October 30. Mr. S. Arnott presided, and introduced Mr. Hosking, who gave a lucid and informative lecture on "Plant Propagation." The subject, one which is, of course, of pre-eminent importance to gardeners and nurserymen, was treated in detail, and the different plans by which plants are propagated received due notice, a number of limelight slides being exhibited to further illustrate the lecture. Mr. Hosking managed to condense within the limits of the lecture a vast amount of information regarding the principles and modes which govern the different processes, and many details were given which proved of much interest to the audience. He was accorded a hearty vote of thanks at the close of the lecture.

OBITUARY.

MR. ADAM BRYDON.

On November 3 there passed away, after a short illness, one of the widest-known and most respected of Scottish amateur gardeners, Mr. Adam Brydon, Innerleithen. Mr. Brydon, who was in his 63rd year, occupied with his brother two farms, Tweedbank and Birks, and was a successful exhibitor. He cultivated everything he took in hand with characteristic thoroughness, and at the leading Scottish, and at some of the principal North of England exhibitions, he proved himself a competitor difficult to beat. He was highly successful at the Edinburgh shows, especially with hardy herbaceous flowers, and many of the leading prizes fell to him year after year. He was imbued with the true sportsman's spirit, and when he was beaten took it well, while he was never unduly elated with his successes. Mr. Brydon took a warm interest in the affairs of the Royal Caledonian Horticultural Society, of which he was an active member, and his presence at the spring and autumn exhibitions of the society will be much missed. He was also a life member of the Scottish Horticultural Association. In private and public life Mr. Brydon was much respected, as will be seen when we mention that he was appointed a J.P. for his native county, Peebles, that he was an ex-Bailie of the burgh of Innerleithen, and a member of Traquair School Board.

MR. ANTHONY HALL.

The death, from pneumonia, of Mr. Anthony Hall, at the age of seventy-eight years, terminates a long career of fifty-six and a half years' service as head gardener at Park End, Wark-on-Tyne. Mr. Hall commenced as an apprentice in Nunwick Hall gardens in 1845, where figs, etc., were grown on flued walls, and lawns were mown with scythes. From Nunwick he went to The Hermitage, near Hexham, as journeyman; and from there to Park End in 1857. He was highly esteemed by each of the four generations of the old Northumberland county family of Ridley, descendants from Bishop Ridley. To commemorate his fifty years' service, he was presented by his employer, C. N. Ridley, Esq., with a suitably-inscribed silver tea service. His wife died in September, 1907. Of the family of four sons, two are alive. The elder—Mr. William Hall—follows the same profession, having the charge of the Corporation parks in Sunderland, where he has been for over twenty-three years.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of THE GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

DATES OF EXHIBITIONS.—A. E., Notts: We are giving the matter our careful consideration. If, as sometimes happens, we fail to notify an exhibition that takes place the following week, it is because the secretary of the society in question has not furnished us with either date or schedule. We are glad at all times to receive show dates from responsible persons, and perhaps you can help us; a postcard is sufficient.

BEST DOZEN SPECIES OF PYRUS FOR SPECIMEN OR AVENUE TREES.—J. E. C., Hailsham: Please give me the names of the best dozen tall-growing species of pyrus suitable for specimen or avenue planting.—When there are so many beautiful trees in a genus, as in the case of pyrus, the selection of half a dozen is no easy task. Taking all things into consideration, we think there will be little to quarrel about in the following list: Pyrus Area, P. Aveuparia, P. baccata, P. communis, P. floribunda, P. germanica, P. Malus, P. prunifolia, P. Sorbus, P. spectabilis, P. Forminalis, and P. vestita. We may point out that, beautiful as many of the species are, the varietal forms are, in many cases, even more beautiful.

ACHYRANTHES VERSCHAFFELTI OR IRISINE HERBSTI.—A. R., Coventry: In a garden I have recently taken charge of there is a foliage plant labelled Achyranthes Verschaffelti. This name I am not familiar with, and it does not appear in any list or catalogue I possess. The plant seems to be an irisine, and so I am wondering whether the name is a synonym; perhaps you can help me.—Without a specimen to help us, we cannot say what the plant is, but if it was correctly labelled originally, then it should be Irisine Herbsti, as this is the proper title for the plant known some time as Achyranthes Verschaffelti. There are several varietal forms, but the type has crimson leaves and stems.

ABUTILON VITIFOLIUM.—N. E. C., Southampton: I have a plant of Abutilon vitifolium growing close to a wall in a sheltered place, and it has done well this year. I should like to propagate a few plants from it, and shall be glad if you will tell me how to proceed.—Cuttings of the young growth will root in a temperature of 65 to 70 degrees if treated as other abutilons, and finally hardened off, but very young plants should not be planted out, or they may succumb to the winter wet and cold; it is better to keep them in a frame for the first winter.

BLACKENED CHRYSANTHEMUM FOLIAGE.—W. F. E., Sussex: I enclose a few leaves of chrysanthemums, primulas, and begonias, and shall be glad if you will kindly say what has caused the disfigurement. I am inclined to think that the same trouble is affecting all the plants. The chrysanthemums were first attacked. Would eelworm in the soil, or an overdose of chemical manure, be likely to cause the disfigurement?—In our issue of October 18 we dealt with a similar case of blackened chrysanthemum leaves, and pointed out that an insect which punctures the foliage is the cause of the decay; you will find the reference on page 794 of that issue. The begonia leaves show a slight attack of mite, which can be checked by the use of tobacco dust, but the leaves suggest that there is some other weakening cause, and probably this can only be found in the soil, or in fumigation while the leaves were moist.

MARKET CERTIFICATES FOR CHRYSANTHEMUMS.—J. S., Exeter: In accordance with our promise on p. 854, we now give the scale of points used by the National

Kelway
of Langport, Somerset

LOVELY DELPHINIUMS

Kelway's Delphiniums grow to a height of from four to eight or more feet and bear masses of fine shapely blooms in all shades of blue and purple. They thrive with a minimum of attention in almost any soil and situation, and they provide a bold and beautiful show either massed by themselves or as a part of the Kelway Colour Border.

KELWAY COLOUR BORDER (Regd.)

To secure absolute perfection in your Herbaceous Border, stock it with Kelway Hardy Perennials. Their bold forms and lovely colours represent the outcome of years of patient experiment and hybridization, while they are raised from such strong country-grown stocks that they may be depended upon to flourish under almost all conditions of climate.

NOW IS THE TIME TO PLANT

Write for GARDENS of DELIGHT 6d. post free.

Chrysanthemum Society's Floral Committee when adjudicating upon varieties submitted for a Market Certificate. The name of the variety is given, the colour is then determined, and the classification settled. Maximum points are: Flower—colour, 20; Form, 20; Fullness, 10; Petal, 10; Stem, 10; Foliage, 10; Habit of plant, 20; total, 100. Singles are pointed on similar lines for Market Certificate. A minimum of 80 points is necessary for a First Class Certificate and 70 points for a Commendation. The voting papers are collected, and the average of points taken. Thus, if there are a dozen voting papers, and the pointing is 72, 75, 79, 80, 84, 87, 89, 86, 86, 89, 91, and 90, the total would be 1,008 points, or an average of 84, and so the variety voted on would receive a Market Certificate.

PEAR LEAF BLISTER MITE.—J. P., Coventry: My pear trees, planted two years ago, are infested with the Pear Leaf Blister Mite. Referring to your article of May 17, will you please say whether it would be advisable to lift the trees this autumn, and dress the roots with lime-sulphur wash. When the trees were planted, the soil was composed of sound turfy loam; would it be well to add some lime now? Also kindly say what proportions of lime and sulphur should be used.—Gather up all leaves that fall from the infested trees and burn them, and at the same time carry out any necessary pruning, and burn the prunings. The reason for this carefulness is that mites may remain in the leaves, and are certainly hiding in the bud scales, from whence they will come forth early in the spring, puncture the leaves, lay eggs, and so start a new generation, which, in turn, further attacks the leaves, and lays more eggs. Do not lift the trees unless they have made excessive growth and need root pruning, which is not very likely, but as soon as the leaves and prunings have been dealt with, remove the surface soil to the depth of two inches, and in its place put some sound loam mixed freely with old mortar rubbish or lime. Spraying with the lime-sulphur-soda wash may be done any time after the present month; the proportions are 1½lbs. each of lime, flowers of sulphur, and salt, a half-pound of caustic soda, and five gallons of water. Mix the sulphur in hot water, and, while stil hot, use it to slake the lime, to which first add the soda. Stir the whole vigorously, but carefully, and add the salt. The lime will generate so much heat that the whole of the mixture will boil for some time; when it ceases to boil, make up to five gallons by adding sufficient soft water; strain and use. February is probably the best time to use this spray mixture for the purpose of arresting the pear leaf blister mite (Eriophes pyri).

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

M. P. W., Bude.—Veronica cupressoides.

D. C., Chesham.—1, Genista pilosa; 2, Thymus villosus; 3, Sedum anacampseros.

S. M. W., Salisbury.—1, Crassula lycopodioides; 2, Cardiospermum Halicacabum; 3, Hibiscus abelmoschus.

P. T. V., Hadham.—1, Nerine Fothergilli; 2, Skimmia japonica; 3, Cotoneaster rotundifolia; 4, apparently the leaves of Magnolia stellata; 5, Lilium nepalense.

R. F. M., Ottery St. Mary.—The roses and chrysanthemums were beyond recognition when they reached us; but, in any case, we cannot undertake to name florists' varieties.

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, GARDENERS' MAGAZINE, as advised in the notice at the head of "Answers to Correspondents."

E. R. B., Rugby.—Oncidium incurvum.

R. H. J., Eccleshall.—Cattleya labiata; a good variety.

M. E. W., Walthamstow.—1, Court Pendu Plat; 2, Beurre Diel.

S. E. L., Chepstow.—1, Cupressus Lawsoniana argentea; 2, Thuia occidentalis.

H., High Wycombe.—1, Smart's Prince Arthur; 2, Gravenstein; 3, not recognised.

J. J., New Brighton.—Sorry your specimen was overlooked recently; it is Ulmus montana.

H. L., Rugby.—1, Hawthornden; 2, Fearn's Pippin; 3, Warner's King; 4, Alfriston; 5, Allington Pippin.

E. J. B., Sodbury.—1, not recognised; 2, probably Margil; 3, Lord Derby; 4, Fearn's Pippin; 5, a small Lord Grosvenor.

H. H. W., Andover.—1, Peasgood's Nonsuch; 2, Not recognised; 3, London Pippin; 4, Catillac; 5, Mabbott's Pearmain; 6, Lane's Prince Albert.

A. B. C., Southampton.—You have broken two of the conditions imposed upon those who send fruits or flowers for naming. There were ten specimens instead of six, and your name and address were not sent. As a matter of courtesy you should have given name and address, not for publication. 1, Baumann's Reinette; 2, King of the Pippins; 3, Waltham Abbey Seedling; 4, not recognised; 5, Adam's Pearmain; 6, Dutch Mignonne; 7, Kentish Fillbasket; 8, Ecklinville; 9, not recognised; 10, Fearn's Pippin.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

MONDAY, November 17.—National Chrysanthemum Society; Floral Committee at Essex Hall, Strand, at 3 o'clock; Executive Committee, at Carr's Restaurant, at 7 o'clock.

TUESDAY, November 18.—Royal Horticultural Hall, Westminster; Committees meet at 12 o'clock; Lecture at 3 p.m.; Scientific Committee at 4 o'clock.

November 18.—Horticultural Club, House dinner at the Hotel Windsor, Victoria Street, Westminster, followed by a lecture entitled "Not about Switzerland," by Mr. Reginald Farrer, 6.30 p.m.

Chester Paxton Society's Chrysanthemum Show; two days.

WEDNESDAY, November 19.—Newcastle Chrysanthemum Show; two days.

Bristol Chrysanthemum Show; two days.

Hull Chrysanthemum Show; two days.

Royal Meteorological Society Meets.

THURSDAY, November 20.—Norwich Chrysanthemum Show; three days.

Paisley Chrysanthemum Show.

Darlington Chrysanthemum Show.

Aylesbury Chrysanthemum Show.

Linnean Society Meets.

FRIDAY, November 21.—Bolton Chrysanthemum Show; two days.

Blackburn Chrysanthemum Show; two days.

Dunfermline Chrysanthemum Show; two days.

Dundee Chrysanthemum Show; two days.

SATURDAY, November 22.—Morley Paxton Society.

CATALOGUES RECEIVED.

A. AND J. C. ALLEN, EARLHAM, NORWICH.—A compact, pocket-sized catalogue of roses, with illustrations and special references to varieties specially suitable for certain purposes.

JAMES COCKER AND SONS, ABERDEEN.—A useful rose list with alphabetical as well as classified lists of varieties, and cultural directions. The same firm issues a catalogue of alpine, bulbous, and herbaceous plants.

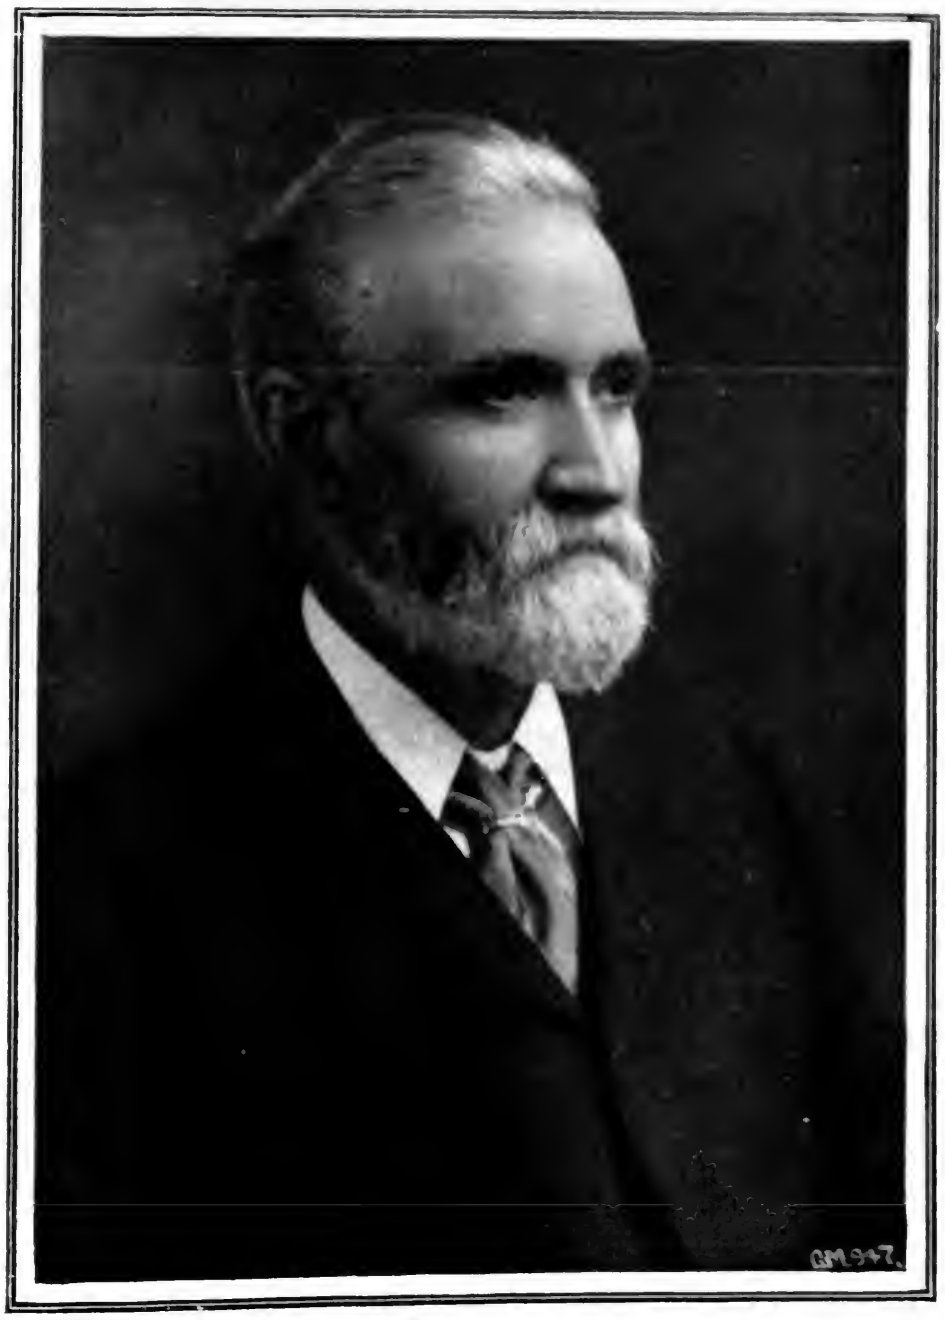
VOL. XVI.—No. 3,134. SATURDAY, NOVEMBER 22, 1913.

THE GARDENERS' MAGAZINE

Mr. GEORGE GORDON, V.M.H.

The retirement of Mr. George Gordon, V.M.H., from the Editorial Chair of THE GARDENERS' MAGAZINE provides the occasion for an appreciation of one to whom horticulture, is greatly indebted, and who, for about five-and-forty years, has used his pen and voice to advance the art and craft of gardening. His name and fame are known wherever horticulture finds a place, especially through the medium of THE GARDENERS' MAGAZINE, with which he has been associated for forty-four years, and of which he has been the Editor since the death of Mr. Shirley Hibberd in 1890. It is of special interest to notice that Mr. Gordon rose from the ranks, and had an early training in practical horticulture before he turned his attention to journalism. His working life was begun under his father, then head gardener at Frogmore Hall, Herts, and one of the most successful fruit growers of his time. From home he went as journeyman to High Leigh, Hoddesden, then famous for its valuable collections of orchids and stove and greenhouse plants. Here he soon attained the position of foreman, and after three years went to Duncombe Park, Helmsley, Yorks, to take charge of the extensive fruit and kitchen gardens. Opportunities for becoming acquainted with farm work were open to him at Helmsley, and these he took such full advantage of that for a time it seemed probable agriculture might claim him. Refusing some excellent offers, however, he remained true to horticulture, and soon afterwards was appointed to the charge of the gardens and farm at Norbiton Hall, Kingston, then an establishment of considerable importance in the London district. When Norbiton Hall and estate were sold Mr. Gordon was appointed to take charge of The Elms estate, Hampton Wick, which belonged to a friend of his former employer. Tall, broad-shouldered, and bearded, Mr. Gordon looked much older than his years, and, indeed, he was only in his twenty-third year when he took charge at The Elms. He was a skilful cultivator, and exhibited with marked success in the Kingston district, so much so that for several years he won practically every prize he entered for, and made a great reputation as a plantsman. Remembering it was not for the good of the society that one man should win all the leading prizes year by year, he gave up competing, but contributed large groups of plants to the exhibition; and in that year, being held in such great respect, he was invited to distribute the prizes. This was probably the first occasion on which Mr. Gordon occupied a prominent position at a public gathering. While at The Elms he began to contribute to THE GARDENERS' MAGAZINE, and a year later he was invited to become Assistant Editor under Mr. Shirley Hibberd. A keen observer, a careful writer, and a great reader, Mr. Gordon further equipped himself for his journalistic work by attending courses of lectures in London on botany, chemistry, geology, agriculture, and other subjects intimately associated with horticulture. It was in the spring of 1888 he suggested to some of his friends that the time was ripe for a conference on all matters pertaining to the fruit-growing industry, then in its infancy. His suggestion was well received, and a committee of sixty-five of the leading fruit growers and nurserymen was formed to carry out the idea, with the result that the first Fruit Conference was held at the Crystal Palace on September 7 and 8, 1888, and proved a great success, a success due chiefly to Mr. Gordon administrative ability. This conference gave a great impetus to fruit culture; indeed, it is not too much to say that the present importance of the fruit industry is due in large measure to Mr. Gordon's pioneer work. The British Fruit Growers' Association was formed after the conference, and Mr. Gordon was elected its vice-chairman. This body held conferences at the Crystal Palace on October 10, 1889; at Shrewsbury; at the Royal Aquarium, Westminster; at the Crystal Palace; at Taunton, and at Brighton in 1890. On August 6 of that year, Mr. Gordon, with Mr. Lewis Castle, Hon. Secretary of the Association, commenced a tour of Ireland, and spent the greater part of the month visiting the counties of Antrim and Derry, Cork, Kerry, and Waterford. Mr. Gordon made this tour at his own charge, for the purpose of investigating and reporting upon the fruit industry in the Sister Isle. His report, as the pages of THE GARDENERS' MAGAZINE show, was read at the Crystal Palace on September 5, 1890, and was of such a character that it attracted the attention of private and trade growers throughout the United Kingdom, and of Government Departments also. The views expressed in the report were widely criticised, and in some quarters were considered to be too optimistic, but as proof that they were based on excellent judgment it is enough to say they have been realised in every case. Chiefly as a result of this report the Agricultural Department of Ireland organised a staff of qualified horticultural instructors, and, under their guidance, the old derelict orchards of Ireland have given place to plantations managed on the most up-to-date lines.



MR. GEORGE GORDON, V.M.H.

In floriculture, no less than in the direction of pomology, Mr. Gordon's work has been, and is, most effective, because his prescience amounts almost to an added sense. Joining the committee of the National Chrysanthemum Society in 1886, he held office for thirteen years, and during that period took a leading part in the preparation of the society's catalogue, published in 1888, and the Centenary Edition of 1911. For his services he received a silver and also a silver-gilt medal, and two years ago was elected an Honorary Life Fellow. Elected a Vice-President of the National Rose Society in 1890, he has taken a very prominent part in the management of this body, and is now chairman of its Publications' Committee. In connection with this and other societies he is always a strong advocate of publications which will prove of value and interest to non-exhibiting members. In a leading article in The Gardeners' Magazine of March 25, 1899, Mr. Gordon pointed out the desirability of special exhibitions of sweet peas, the need of improving methods of staging the flowers, and of bringing the best varieties into greater prominence. The subject was much discussed, and on September 13 of that year a meeting was held in Edinburgh, Mr. Gordon presiding, when it was decided that the bicentenary of the introduction of the sweet pea into England should be celebrated in 1900. A committee was formed, with Mr. Gordon as chairman, to carry out the scheme, and the late Mr. Richard Dean was hon. secretary. How well the celebration was carried out is now a matter of common knowledge. Following this celebration at the Crystal Palace, the National Sweet Pea Society was founded, and came into being at the end of that year. Mr. Gordon was the first chairman of the society, and in 1903 was made President. The National Dahlia Society is now engaging his attention. He was Vice-President from 1891 to 1912, is now President, and, while not overlooking the claims of the dahlia as an exhibition flower, his advocacy of the flower as a suitable subject for garden decoration has brought about a quite new order of things, and made the events of the present year possible. Mr. Gordon's tastes are catholic, and his activities wide in the realm of horticulture. He helped to found the Royal Gardeners' Orphan Fund, and has been a member of its managing body from the beginning. He was also one of the founders of the British Gardeners' Association, and has consistently worked for the material and intellectual advancement of those who gain their livelihood in the gardening profession. In 1897 Mr. Gordon received the distinction of the Victoria Medal of Honour in Horticulture, when that distinction was founded by the Royal Horticultural Society; he has had a seat on the R.H.S. Floral Committee since 1891, and for many years has been a member also of the Scientific Committee. In connection with the Great International Horticultural Exhibition held at Chelsea in 1912, Mr. Gordon was a member of the jury, and of the Educational and Scientific Committee, and used this opportunity to bring into greater prominence the need of a better system of training and education for gardeners. Mr. Gordon has taken part in all the leading horticultural activities of nearly half a century, and on six successive occasions he has been a member of the jury at the Ghent Quinquennial Exhibitions, in addition to acting in a similar capacity at the great international functions at Hamburg, Haarlem, and Antwerp, and his latest appointment is that of vice-chairman of the Horticultural, Arboricultural and Forestry Committee of the Anglo-American Exposition to be held at the White City next year. Although a prolific writer, Mr. Gordon's energies have chiefly found expression in these pages, but he has added "Dahlias," "The Book of Shrubs," "The Wasted Orchards of England," and a long series of "The Gardening Year Book" to horticultural libraries. Altogether this, outline though it is, constitutes a splendid record for one man, and one who served with, and subsequently followed in the Editorial Chair, such a brilliant writer and publicist as Mr. Shirley Hibberd. It is a record of which The Gardeners' Magazine is proud, and one that may well serve to excite the ambition and raise the enthusiasm of the present generation. All our readers will join, with the proprietors and staff, in the wish that the excellent health Mr. Gordon has so long enjoyed may be continued to him for many years to come. It is with special pleasure that we are able to announce his attachment to The Gardeners' Magazine will not be severed, that in the capacity of Advisory Editor his ripe judgment will be at our service, and that he has promised to contribute regularly to the paper he has so long and ably edited.

NOTES OF THE WEEK.

The New Editor of "The Gardeners' Magazine."—The proprietors have much pleasure in announcing that Mr. Charles H. Curtis has taken up the duties and position of Editor of The Gardeners' Magazine. Mr. Curtis served under Mr. Gordon, as Assistant Editor of The Gardeners' Magazine, for nearly twenty-one years, and is well known to our readers.

Marriage of Miss Ellen S. Hibberd.—Those who remember the late Mr. Shirley Hibberd, a former editor of The Gardeners' Magazine, will be interested in the announcement that his only daughter, Miss Ellen S. Hibberd, was married at Kobe, Japan, on November 15, to Mr. Alexander Kennedy, eldest son of the late Dr. David L. Kennedy and Mrs. Kennedy, of Donnybrook, Dublin.

Attempt to Wreck the Palm House at Sefton Park.—Liverpool possesses a superb palm house and winter garden at Sefton Park; indeed, it is one of the finest structures of its kind in the country, and valued at about £20,000. A dastardly attempt, apparently by suffragettes, to wreck this structure, which, with its beautiful contents, add so much to the amenities of Liverpool, was made on Saturday night last, when a bomb, with two fuses attached, was found in the Palm House porch. Evidently the gale blew out the fuses, and so no damage was done. Suffragette literature was found near by, with a postcard on which was written, "Stop torturing God's human plants who are fighting for votes for women."

The Rescue of Box Hill.—For a long time the fear has been ever present that Box Hill, which stands in the midst of some of the most beautiful Surrey scenery, might be lost to the public, and be disfigured by the erection of residences. Mantled in boxwood and yew, and rising 600 feet above the lazy Mole, which skirts its western boundary, Box Hill is a popular and beautiful resort for Londoners, and from its summit glorious views extend over park land and farmsteads, villages and woodlands. Box Hill is part of the Deepdene Estate, and though it has for so long been open to all comers, the public have no rights upon it, save along the paths and roads. When the question of utilising certain portions of the hill for building sites arose, it soon became apparent that the public had no legal rights, although they had long enjoyed many privileges, and so the National Trust and the Commons and Footpaths Preservation Society opened negotiations for the acquisition of the hill for the public use for ever. An option for the purchase of the property was secured, and arrangements were being made for an appeal for funds, when, with great public spirit, Mr. Leopold Salomons, of Norbury Park, Dorking, purchased the hill, and proposes to vest the property in the National Trust, on condition "that it shall be permanently maintained as a public open space, subject to the supervision of a local committee of management, and subject also to the understanding that nothing shall ever be permitted to impair the unique natural features which have added so freely to the enjoyment of countless visitors." The property, secured at no small expense, and thus so generously given to the public, comprises about 235 acres, and includes not only Box Hill proper, but the whole ridge from Burford Bridge to Upper Box Hill Farm, and the valley up which the military road rises easily to the now derelict fort. Mr. Leopold Salomons deserves and receives the heartiest thanks of all lovers of open spaces and beautiful scenery for his splendid gift—a gift which, in the care of the National Trust, will be safely kept for all time.

A Boulevard all Round London is the ideal which Mr. Percy B. Tubbs, F.R.I.B.A., has in view, and, after a trip around the seven-mile radius, he believes that if co-operation between the authorities concerned could be arranged, a boulevard all round the outskirts of London might be provided, but he is of opinion that to secure this ideal no time should be lost in attempting its realisation.

The Scottish Horticultural Institute.—The proposal to found a Scottish Horticultural Institute is finding favour and receiving support. At a bazaar held in conjunction with the Scottish Horticultural Association's Chrysanthemum Show, in the Waverley Market, Edinburgh, on November 13, 14, and 15, the sum of £800 was realised in aid of the proposal.

Wimbledon Park as an Open Space.—The Wimbledon Town Council has decided to promote a Bill in the next Parliamentary Session authorising the Council to purchase the Wimbledon Park estate, at a cost of £65,000, for an open public space. The area under consideration is 155 acres, with a central lake of about 32 acres, the whole constituting one of the most beautiful spots around the Metropolis.

Presentations at Pershore.—Lord Coventry took advantage of the opening ceremony at the Pershore Fruit and Chrysanthemum Show to present a purse of money to Messrs. P. Hanson, T. Milward, and W. Wood, who have acted as honorary secretaries to the Pershore Horticultural Society for a period of ten years. When more prosperous than now the society gave £380 towards the local hospital. The address accompanying the purse stated: "It is with a sense of deep gratitude to you we remember that in the times of the society's financial success many of the useful institutions in the town

were materially benefited from its funds, through your instrumentality, and that, under all conditions, you have maintained the quality and importance of the Flower Show, thereby assisting what has now become the principal industry of the district."

Rosebery Park, Epsom.—It has been agreed that the land given to Epsom by Lord Rosebery, for an open space, shall be called Rosebery Park. His Lordship has also promised £500 towards the cost of laying out the land, and expressed his willingness to act with the Town Council in making the park as beautiful and useful as possible, when the lease of the land falls in.

Illness of Mr. William Collins.—Members and friends of the United Horticultural Benefit and Provident Society will regret to learn that Mr. W. Collins, until lately the veteran secretary of the society, is an in-patient at Guy's Hospital, where he has to undergo a somewhat severe operation. Everyone will join us in the hope that the operation will be successful, and that Mr. Collins will have a speedy recovery.

The Cowper Museum, Olney.—At a meeting of the Trustees of the Cowper Museum last week the secretary reported that during the past year the amount of the donations received had exceeded that of any previous year. To carry out the necessary work, and to provide a modest endowment, £2,000 is needed, and much of that amount has yet to be obtained. William Cowper, the poet, and author of "The Task," resided in the house for nineteen years. The exterior of the building has been restored, but money is needed to enable the interior to be used for the purposes of the Museum. The Museum has now been in existence for thirteen years, and contains a number of interesting paintings and relics of the poet and his friends. The secretary—Mr. Thomas Wright, of Cowper School, Olney, Bucks—will gladly acknowledge donations and provide information in regard to the Museum.

Public Displays of Chrysanthemums in the North.—Splendid displays of chrysanthemums have been, and are still being, provided for the public at Miller Park, Preston, where Mr. Tye has a grand lot of both Japanese and single varieties; at Manningham Park, Bradford, where, in the fine conservatory, where chrysanthemums vie with Begonia Gloire de Lorraine (two hundred plants) and orchids; at West Park, Hull, where November 9 was observed as Chrysanthemum Sunday; and at Dewsbury, where, in the beautiful conservatory presented to the inhabitants by Miss Tweedale, Mr. W. Daniels has excelled himself both in the cultivation and arrangement of the Queen of Autumn.

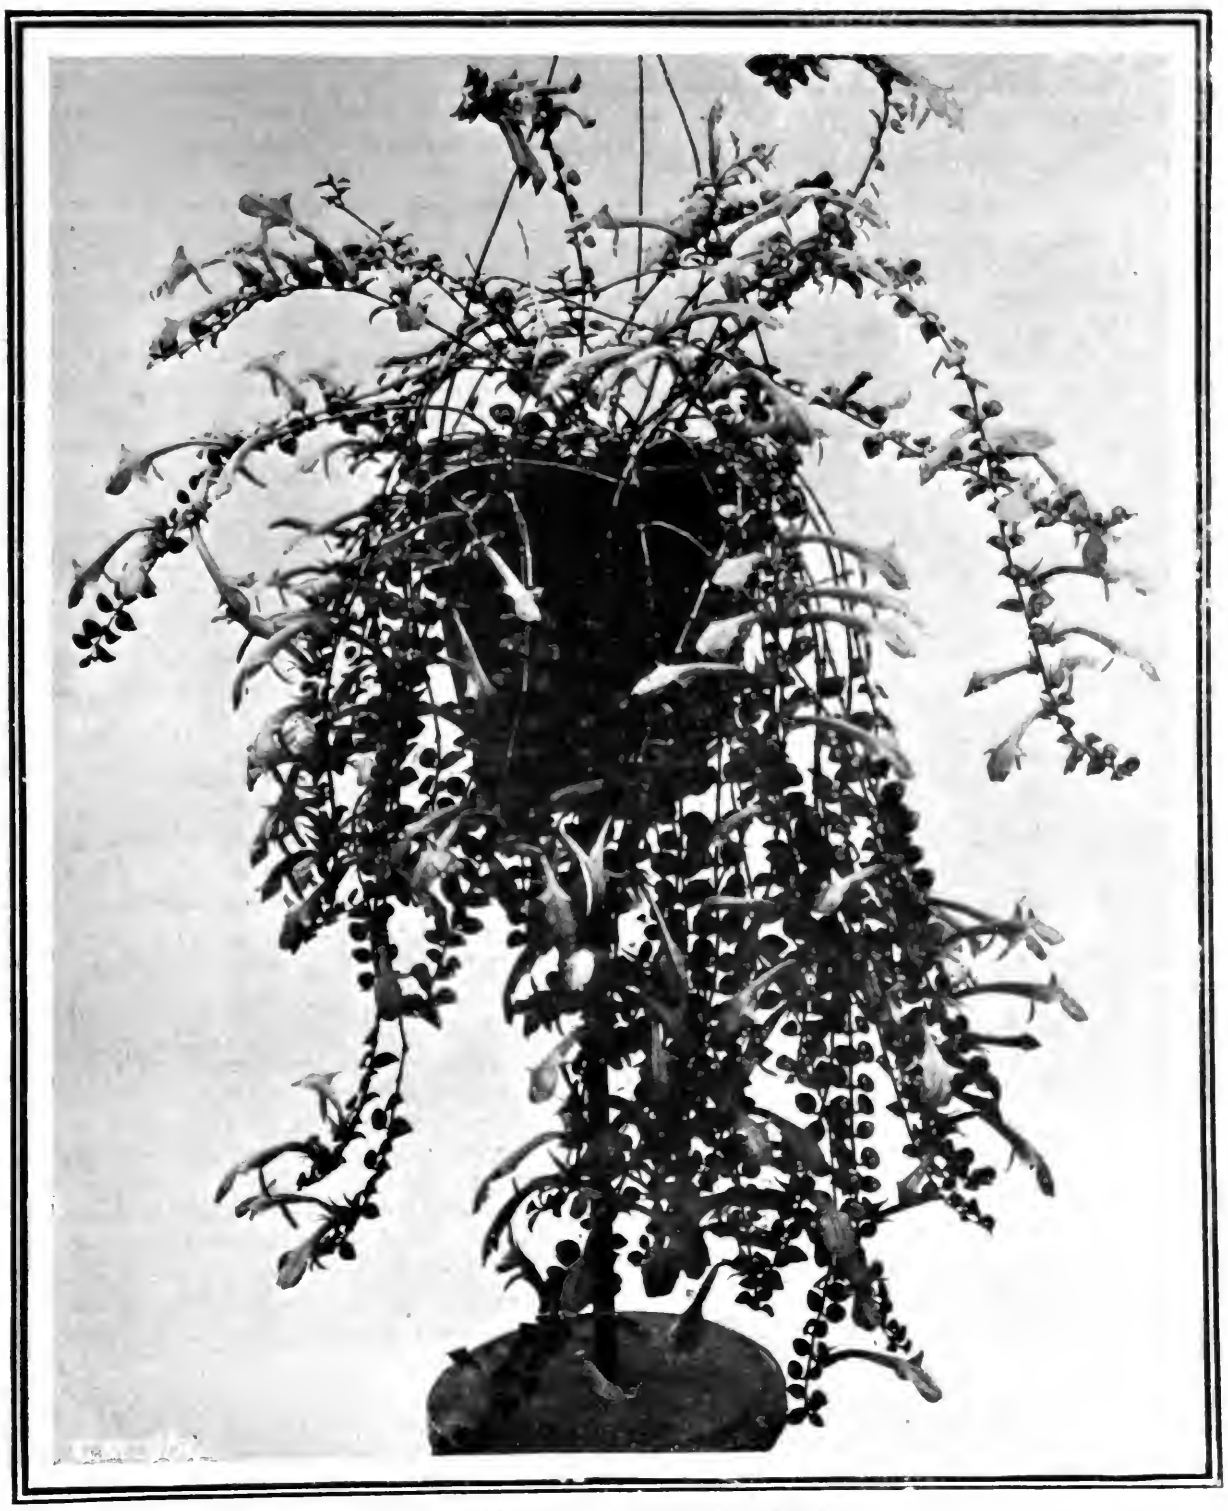
Prosecutions under the Wart Disease of Potatoes Order.—Three cases came recently before the Mansfield Petty Sessions, under the Wart Disease of Potatoes Order, 1912. It was claimed that the defendants had planted potatoes on infected premises, in contravention of an order prohibiting such planting except under a licence granted by an inspector authorised to administer the Order under the Board of Agriculture. Licenses are only granted, it appeared, to those who plant potatoes immune from the disease. The extreme penalty is £10. As these were the first cases taken in the district, two of the defendants were ordered to pay the costs, 5s., and the third case was dismissed.

ROYAL HORTICULTURAL SOCIETY.

The exhibition held at Westminster on November 18 well filled the Royal Horticultural Hall, and proved of great interest to the large numbers of visitors present. Chrysanthemums, winter-flowering begonias, and orchids were the leading features of a first-rate November show.

BEGONIAS AND CHRYSANTHEMUMS.

Messrs. Clibrans, Altrincham, filled an entire table with winter-flowering begonias, which were splendidly grown, and covered with fully-developed flowers. The most striking were Miss Clibran, rose pink, The Gem, Lady Cooper, Apricot, Scarlet Beauty, and Beauty of Hale, in splendid form, the whole making up a wonderful bank of colour-



COLUMNEA OERSTEDIANA.

A beautiful gesneraceous plant with orange-coloured flowers, borne on pendulous growths. F.C.C., R.H.S., November 18. Sir Trevor Lawrence, Bart., Dorking.

ing. Messrs. W. Cutbush and Son, Highgate, also staged a fine table of winter-flowering begonias, backed with palms, ferns, etc., and edged with Ficus repens variegata. The begonias were beautifully developed in four-inch and five-inch pots, and the chief varieties were Beauty of Hale, Winter Perfection, Lady Waterlow, Elatior, Mrs. Heal, Bowdon Beauty, and Rochfordi.

A fine group of begonias came from Sir Corbet Woodall, Walden, Chislehurst (gardener, Mr. W. Thoms). The plants were large specimens, some being at least three feet in diameter; all were magnificently flowered and tastefully arranged in a bed of ferns and Panicum variegatum. Messrs. Rasmussen and Crone, Woodbine Nurseries, Wanstead, N.E., staged a fine display of winter-flowering begonias, which were remarkably well grown, and included all the popular types.

Messrs. Jas. Veitch and Sons, Lim., Chelsea, filled an entire table with their winter-flowering begonias. These were arranged in blocks of colour, and presented a very striking appearance. The best were Fascination, a rich salmon variety; Syros, a charming orange-buff colour (A.M.); Julius, Emita, bright orange scarlet; Mrs. Heal, in splendid form; Optima, Elatior and Winter Cheer. The whole exhibit formed a most striking demonstration of the usefulness of these valuable winter-flowering plants. The Chelsea firm also exhibited a grand group of dwarf chrysanthemums in pots arranged in the central position of the hall.

Messrs. H. J. Jones, Lim., Lewisham, again staged a fine collection of chrysanthemums, arranged very much on the same lines as at the last meeting. The huge stands used to form the background were filled with Mrs. Gilbert Drabble, Miss Roope, Mrs. H. J. Jones in splendid form, Maud Louisada, a fine variety; Mrs. J. B. Riding, and Mrs. W. T. Smith. The front was filled with singles and decorative varieties, arranged in large masses, the whole forming a fine display. Mr. C. J. Simpson, Chelmsford, also contributed a display of single varieties in good condition.

Messrs. W. Wells and Co., Merstham, filled a long table with chrysanthemums displayed most artistically in a free and open arrangement. The huge show flowers came in for a lot of attention, while the single varieties proved no less attractive. The largest varieties were Mrs. Gilbert Drabble, W. Turner, James Fraser, Mrs. G. Drexel,

Frances Jolliffe, Queen Mary (a huge mass of blooms), H. E. Converse, and Daily Mail. The single varieties were equally well grown, and perhaps the most striking were Peter Barnes, Mrs. Whitehorn, Lady Mowbray, Isobel Felton, Golden Mensa, and Snow Queen. The Misses Price and Fyfe, Grove Park Nursery, Lee, S.E., staged a collection of chrysanthemums in tall stands.

A bright bank of chrysanthemums came from the Marchioness of Ripon, Coombe Court, Kingston Hill (gardener, Mr. T. Smith), but the lack of greenery was all too apparent. The chief features were the masses of Arcturus, Mrs. C. H. Totty, Doreen, Mrs. Rider Bird, very like Bronze Soleil d'Octobre, and Godfrey's King. Chrysanthemums of the single and decorative types were well represented by Messrs. J. Peed and Sons, West Norwood, and each variety was staged in quantity, so that a good general effect was produced. The most striking single forms were Stuart Smith, Doreen, Sam Allcock, C. J. Ellis, and Mrs. W. Buckingham.

GREENHOUSE PLANTS AND CARNATIONS.

A high decorative group of poinsettias and chrysanthemums was staged by Miss Baird, St. James' Gardens, West Malvern (gardener, Mr. J. W. Irvine). The poinsettias were arranged in tall stands, associated with sprays of variegated abutilon, while big columns of single chrysanthemums were utilised in conjunction with asparagus and smilax. Messrs. H. B. May and Sons, Upper Edmonton, N., filled one table with a miscellaneous exhibit consisting of ferns, hydrangeas, winter-flowering begonias, a fine variety of cyclamen in flower, and a number of Primula obconica hybrida.

Messrs. Whitelegg and Page, Chislehurst, had a large exhibit of single chrysanthemums, arranged in vases, which embraced all the popular varieties. From Mr. A. H. Cole, Swanley, came a bright exhibit of zonale pelargoniums, also some single chrysanthemums in vases. In the latter were noted Excelsior, Mabel Bath, Honeysuckle, and Sandringham. Messrs. H. Cannell and Sons, Eynsford, presented a fine display of zonale pelargoniums, in which were noted Frogmore, King Victor, Vesta, Dublin, Countess of Jersey, and Sir Thos. Hanbury.

A remarkably bright display of carnations came from Mr. C. Englemann, Saffron Walden, Essex. The chief varieties were Carola, in fine colour; Circe, a fine variety, after the Mikado type, but of fancy colouring; Pioneer, Triumph, and Fanny were also noted. Scarlet Carola was bright, while Variegated Carola could not be overlooked on account of its quaint colouring. A bright display of carnations was exhibited by Messrs. Stuart Low, and Co., Bush Hill Park, N.

Messrs. Allwood Bros., Haywards Heath, exhibited some of the newer carnations in vases and tall stands, in which were to be seen Wivelsfield White, Cinderella, heliotrope and cerise; Empire Day, in grand form; also Mary Allwood in fine colour. Messrs. W. Cutbush and Sons, Highgate, staged carnations in pots, as well as in vases. These were arranged with palms, ferns, and other desirable foliage.

A fine group of gesneras was staged by Mary Countess of Lovelace, Ockham Park, Ripley (gardener, Mr. Towell). The plants were growing in five-inch and six-inch pots, with perfect foliage and well-developed flowers, giving evidence of considerable cultural skill. Messrs. Wills and Segar, Onslow Crescent, Kensington, staged baskets of Gerbera Jamesoni, in fine colour for the season, also some well-grown cyclamen.

HARDY PLANTS.

Mr. Jas. Box, Lindfield Nurseries, Haywards Heath, presented a small display of hardy shrubs and flowering plants. Pans of Iris alata and I. Vartani were conspicuous, as were also vases of Berberis Darwini, Aster amellus Framfieldi, and the brilliant Berberis Thunbergi. From Messrs. J. Piper and Sons, Bayswater, W., came an interesting exhibit of miniature Japanese gardens, which attracted much attention. These were very quaint, and doubtless found many admirers. The Wargrave Plant Farm, Lim., The Arcade, Liverpool Street, E.C., had an exhibit of alpines arranged among stones; we noticed Mazus rugosus, and a variety of dwarf conifers suitable for rock work. The arrangement was rather unique in such a small space.

From Mr. Clarence Elliott, Six Hills Nursery, Stevenage, came a variety of conifers suitable for rockwork, also a nice collection of alpines, in which Gentiana acaulis and Achillea tomentosa were noted; while Androsace lanuginosa and Morisia hypogæa were also in evidence. An entire table was occupied with variegated foliage and berried plants filled by Mr. L. R. Russell, Richmond Nurseries, Richmond.

From Messrs. T. S. Ware, Lim., Feltham, came an interesting display of alpines, the background being filled in with dwarf-growing conifers, and Lauruetinus nicely in flower. Mr. J. J. Kettle, Corfe Mullen, Wimborne, brought a collection of remarkably well-grown violets, which attracted much attention, the varieties Princess of Wales and Mrs. J. J. Astor being most conspicuous.

A small table of nasturtiums in pots came from the John Innes' Horticultural Institute, Merton, Surrey: there were well-flowered plants of the double scarlet and double yellow varieties. These are the produce of a double yellow variety, crossed with a small dark variety having variegated foliage; the progeny from self-fertilised seeds of the hybrid, sorted themselves out as above, some with green and some with variegated leafage. Mr. G. Reuthe, Hardy Plant Nursery, Keston, contributed a pretty group of hardy plants, where the central subject was Erica mediterranea hybrida; he also had a fine variety of nerines, the best being M. Manselli.

Mr. G. Prince, Longworth Nurseries, Oxford, staged a grand exhibit of roses that would have done credit to an early autumn show. The arrangement was decidedly good, and the varieties Frau K. Druschki, Lady Hillingdon, Pharisaer, Hugh Dickson, La Tosca, Irish Elegance, Rayon d'Or, and White Maman Cochet were in capital form.

ORCHIDS.

Messrs. Stuart Low and Co., Bush Hill Park, contributed a small collection of orchids, staged in a groundwork of maidenhair ferns. A few of the most striking features were Cattleya labiata alba, Cattleya Fabia, two good varieties of Vanda cœrulea, some good oncidiums and Brasso-cattleya Fournieri Crowborough variety, and a few choice cypripediums. Messrs. Flory and Black, Slough, contributed a pretty group of odontoglossums, cattleyas, and cypripediums; the latter included some choice forms. From Messrs. W. Baylor Hartland and Sons, Cork, came a nice group, chiefly composed of cypripediums, cattleyas, and odontoglossums. The cypripediums were, however, the feature of the exhibit.

Messrs. Charlesworth and Co., Haywards Heath, had a most imposing display. The odontoglossums included O. crispum Mabel Wheatley, O. laudatum—a splendid form with rich colouring—O. eximium xanthotes, a yellow-spotted variety; and O. eximium, a fine blotched variety. The group was also rich in cattleyas, vandas, and oncidiums, and contained a fine example of the new white-flowered Angræcum recurvum (A.M.). Messrs. Jas. Veitch and Sons, Lim., Chelsea, contributed a collection of orchids, the chief attraction being the groups of calanthes, which were well flowered, especially C. Veitchi, C. V. rubro-oculata, and C. Harrissi.

Messrs. Hassall and Co., Southgate, also contributed a small group, chiefly of cypripediums and cattleyas; while Messrs. J. Cypher and Sons, Cheltenham, presented an attractive display. The cypripediums were the chief feature here, C. Venus var. Boltoni, with two flowers, being much admired.

Mr. Francis Wellesley, Woking; Mr. O. Wrigley, Bury; Sir George Holford, and others also showed a few orchids, some of which secured awards as notified below.

FRUITS.

The chief exhibit of fruit in the hall was a large table of apples from Messrs. J. Cheal and Sons, Crawley. The fruits were arranged in baskets and dishes, and were remarkable not only for their fine size, but for their very brilliant colouring. This latter point was certainly enhanced by the attractive vine and other leaves employed. Some of the most attractive varieties were Bismarck, Lord Derby, Mère de Ménage, Annie Elizabeth, Sandringham, Nelson Codlin, Winter Queening, Rymer, Crawley Beauty in great form, Bramley's Seedling of fine colour, Blenheim Orange, and Newton Wonder. It was difficult to pick and choose between the dishes where all were so good. Lady Lovelace, Ockham Hall, Ripley, sent excellent fruits of Surprise d'Automne and Everbearing Feldebrunner raspberries.

CERTIFICATE AND AWARDS.

First-Class Certificate.—To Columnea Oerstediana, from Sir Trevor Lawrence, Bart. (gardener, Mr. W. Bain), Burford Lodge, Dorking.

Award of Merit.—To Cypripedium Cyclops, from Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury; to Cattleya Feronia, Charlesworth's var.; and to Angræcum recurvum, from Messrs. Charlesworth and Co., Hayward's Heath; to Dendrobium Leeanum, Langley var., from Messrs. Flory and Black, Langley; to Miltonia Harwoodi, The Shrubbery variety; and to Cypripedium Kentore, from Messrs. Armstrong and Brown, Tunbridge Wells; to Chrysanthemum Mary Morris, from E. G. Mocatta, Esq. (gardener, Mr. Thos. Stevenson), Woburn Place, Addlestone; and to Begonia Syros, from Messrs. Jas. Veitch and Sons, Chelsea.

MEDALS.

Gold.—To Messrs. J. Cheal and Sons, Crawley, for fruit.

Silver-gilt Flora.—To Messrs. Jas. Veitch and Sons, Chelsea, for begonias and chrysanthemums; to Messrs. W. Wells and Co., Merstham, for chrysanthemums.

Silver-gilt Banksian.—To Messrs. H. J. Jones, Lim., Ryecroft, Lewisham, for chrysanthemums.

Silver Flora.—To Messrs. Clibrans, Altrincham, for winter-flowering begonias; to Mr. L. R. Russell, Richmond, for berried shrubs; to Mr. G. Prince, Longworth, for roses; to Messrs. W. Cutbush and Son, Highgate, for begonias and carnations; to Messrs. Charlesworth and Co., Hayward's Heath, for orchids; to Messrs. Jas. Veitch and Sons, Chelsea, for orchids.

Silver Banksian.—To Messrs. Allwood Brothers, Wivelsfield, Hayward's Heath, for carnations; to Messrs. H. Cannell and Sons, Eynsford, for zonale pelargoniums; to Mr. C. Engelmann, Saffron Walden, for carnations; to Miss Baird, West Malvern, for poinsettias and chrysanthemums; to Sir Corbett Woodall, Chislehurst, for Begonia Gloire de Lorraine; to Messrs. J. Cypher and Sons, Cheltenham, for orchids; to Messrs. Flory and Black, Langley, for orchids; to Messrs. W. B. Hartland and Sons, Cork, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; to Messrs. Hassell and Co., Southgate, for orchids.

Bronze Flora.—To Mr. A. H. Cole, Swanley, for zonal pelargoniums; to Mr. Kettle, Corfe Mullen, Wimborne, for violets; to Messrs. Stuart Low and Co., Enfield, for roses and carnations; to Messrs. J. Peed and Son, West Norwood, for chrysanthemums; to Messrs. Rasmussen and Crone, Wanstead, for begonias.

Bronze Banksian.—To Misses Price and Fyfe, Lee, for chrysanthemums and carnations; to Mr. C. J. Simpson, Chelmsford, for chrysanthemums; to Mary Countess of Lovelace, Ockham Park, Ripley, for gesneras.

NOTES FROM THE ARNOLD ARBORETUM.

The number of trees and shrubs at present (November 4) brightening up the late autumn days with their showy fruits is considerable, and so a note on a few of the choicer ones may be of interest to those who live in the "old country."

The Black Alder or Winterberry (Ilex verticillata) is a native of the U.S.A., and forms erect-growing bushes, 5ft. high, that are now completely covered with a blaze of scarlet berries, and are decidedly attractive. Ilex lævigata, also a native, is very similar in appearance, except that the berries, although quite as dense, are hardly as deep in colour. The Ink Berry (Ilex glabra) has a more spreading habit, with a dense head of leaves, among which are innumerable small black berries. It is about 3ft. high. Similar berries are produced on Ilex crenata microphylla, from Japan, represented by compact-growing bushes that are 4ft. high, with small, shining foliage.

Lonicera Maacki var.podocarpa should find a place in every collection. It is a splendid, late-fruiting honeysuckle from China, with a remarkable number of berries, quite a dark red, gleaming everywhere on bushes 5ft. to 6ft. high, while the long, green, pointed foliage is still retained. Lonicera Maacki is quite as freely fruited, but the berries are smaller, and not so deep in colour as those of the variety, and it loses its leaves much earlier.

Euonymus radicans vegetus, from North Japan, is a low-spreading bush about 3ft. high, and presents a bright appearance by the side of a driveway, with its clusters of showy scarlet berries. Euonymus alatus is a much-branched shrub with curiously-winged branches, and grows 8ft. high and about 10ft. through, and, although but sparsely fruited, its chief beauty lies in the bright scarlet hue of its foliage, which is the first of all to colour up with the approach of autumn. Euonymus Hamiltonianus semipersistens is different to the other species, and forms quite a small tree, 10 to 12ft. high, of erect habit and with its foliage still green; while shrubs of E. Hamiltonianus (type) are quite bare. The home of the variety is unknown.

Cornus florida was very attractive a few weeks ago, with its clusters of large red berries on bushes 12ft. and more high, but these have now all fallen off, as also have the dark fruits of Cornus Mas. During September I came across a fine shrub of Cornus Kousa in Mount Auburn Cemetery, Mass., bearing quite a number of fruits; it was a shrub about 8ft. high, with a spreading habit. The Tupelo Tree (Nyssa sylvatica) is represented in the Arboretum by trees about 25ft. high, covered with grape-blue fruits; it likes a damp situation to grow in. Benzoin destivale (Lidera Benzoin), the Spice Bush, or Benjamin Bush, which grows wild in our neighbourhood, was a blaze of scarlet fruits about a month ago, but these have now fallen.

The Washington Thorn (Cratægus cordata) is conspicuous in many places, with its brilliant, small red berries; and many other species are also making a grand show on a hill-side in the Arboretum. Berberis vulgaris and its varieties form groups in several places, and are loaded with fruits; while fine specimen bushes of Viburnum Opulus, and its American form, V. Americanus, are both very attractive with their large clusters of red fruit.

Wm. H. Judd.

Arnold Arboretum, Mass., U.S.A.

CYCLAMEN MRS. BUCKSTON.

For many years past the Rev. H. Buckston, J.P., Sutton-on-the-Hill, Etwall, Derby, has taken a keen interest in cyclamen, and his gardener, Mr. Shambrook, has proved a most accomplished cultivator of these useful winter-flowering subjects. Moreover, improvement has been carried out until a splendid strain has resulted, the plants free and sturdy, and carrying substantial blooms in plenty, well above the foliage. It is with frilled flowers, however, that the most obvious improvement has been made, and when Mr. Shambrook brought up a large group of cyclamens to a meeting of the Royal Horticultural Society last February, everyone admired the variety herewith figured, and named Mrs. Buckston. In this variety exquisite frilling has been secured without loss of vigour, and without in any way spoiling the elegance of the flowers—indeed, frilling is an added grace in this case. At the Derby Chrysanthemum Show, held a week or so ago, Mr. Shambrook staged a very fine collection of indoor-flowering plants, and conspicuous among these were the finely-grown examples of Cyclamen Mrs. Buckston. The specimen illustrated indicates the beauty of the varieties, and Mr. Shambrook's skill as a cultivator.

CYCLAMEN MRS. BUCKSTON.

A frilled pink variety, raised by the Rev. H. Buckston, Etwall, Derby.

ENTHUSIASM IN NOVEMBER.

The fair-weather amateur who remembers he has a garden in March gets tired of it by the end of July, and thinks no more of it after the holidays, wonders what there can be to do in November, while the idea of getting enjoyment out of the work is altogether beyond his imagination. There is no quicker and surer way of finding out the extent of a stranger's interest in gardening than by directing the conversation to some of the routine work suitable to November. It is the month of all months for planting and transplanting fruit trees, roses, and most hardy perennials and shrubs, and for making alterations generally. The latter especially can be done with greater freedom at this season than at any other; the soil often works better, being moist to any depth without being saturated, except perhaps near the surface after recent rains, while the neat and well-cultivated appearance of things, after the work is done, is a joy to look at through the winter. It is not only the enjoyment of doing the work at this season in the bracing weather, when most people are in as good physical condition as at any time of the year, but it is the delight and satisfaction of carrying out the plans which have been in our minds during the summer and early in the autumn and we have been longing to put in hand ever since.

It is said that in gardening we have always the pleasures either of retrospection or of looking forward; but in November we have both, and, in addition, a considerable amount of actual happiness in viewing actual present accomplishment. The early part of the month should be a busy time gathering in the fruits of the earth and storing them, while there should still be a good deal waiting the time of our need, such as celery, celeriac, leeks, turnips, and the various members of the cabbage family. The making up of the clamps of beet and carrots gives one a happy sense of possession without the accompaniment of selfishness, and the stores of apples and pears likewise; and we can feel that in our leisure we have added this much wealth to the country, and not obtained it at the expense of anyone else.

The stores of fruit indoors are, perhaps, one of the greatest sources of pleasure of the whole round of the year, for no thorough-going fruit grower will leave this at the absolute discretion of the genius of the kitchen. He knows, as no one else should know, when apples and pears are in their best condition either for cooking or dessert; and if he does not yet know this in the case of certain varieties, it is of the greatest interest to find out by experience, and make mental notes for guidance another year, from which not only himself but the whole household will derive pleasure and profit. A man may study this subject for many years without finding he is always prepared for the vagaries even of his most familiar varieties; 1912 beggared the experience of many veterans in this respect—as, for instance, in the case with me of Josephine de Malines pear, which, notwithstanding the cold summer and autumn, was ready for dessert at the end of November, whereas usually it is allowed to hang on the tree till the middle of that month, and is not expected to be in season before January or even February. Only a keen and intelligent inspection can be ready for such unexpected happenings, for it is scarcely necessary to say that the pernicious habit of squeezing pears is absolutely taboo to the fruit connoisseur. It needs some amount of experience and almost loving study before we can tell by appearance only when such green or russety varieties as Winter Nelis, Glou Morceau, and Olivier de Serres are just becoming ready for use. When they are changing to yellow it is probable they are already too far gone, or will be before we have enjoyed them many days. The head of the house need not be ashamed to make this his own peculiar province, and it will give him many an hour's happiness late in the evening when he is too tired for much else, and the results will be seen in good things for others.

Of course the townsman and the half-hearted amateur will say there is no daylight for the outdoor work of the garden at this season. But where there's a will there's a way. Even late in November, if breakfast is at any reasonable time, an hour may be obtained before it, and even more, for work that does not want too good a light. I know of no garden work at any season of the year more really delightful than an hour's honest digging before breakfast on a crisp frosty morning. The ground digs splendidly, one gets in a glow which makes one feel ten years younger, and the work can be done without that undue amount of perspiration which is apt to be attendant upon it at most times. And afterwards there is the zest of breakfast!

This is the time for two or three-spit digging, and most of the garden refuse of a decayable nature can be put underneath the third spit, and will never be seen again except as a little humus in the otherwise light-coloured soil when we dig as deeply there again in two or three years' time. This is the best time of the day and year for the work, and it is a good plan to reserve it for the first thing every morning, so as not to use the full daylight for it, and also to warm us up when we are most likely to get a chill. Alger Petts.

LATE PEARS.

Mr. Princep's article on late pears is a very practical one, but allow me to say that I would not advise planters to try Forelle pear, because, while it is the most beautiful of all, the least bruise or rot causes it to become intensely bitter, and it seldom comes quite clear of spots or blemishes. Beurre Sterckmanns is of good quality, but very liable to spot and crack. Hughes' Victoria has practically run out of cultivation. I consider Prince of Wales was Hughes' best pear, but even that is rarely grown now.

A few late pears that have recently come to the front are The Blickling, very rich at Christmas, at which period Santa Claus is also first-rate. Roosevelt is a handsome, clean-skinned pear, often highly coloured; and Beurre de Naghin is also fine. These four have received recognition from the Royal Horticultural Society's Fruit Committee. Older sorts worth growing are Duchesse de Bordeaux and Doyenne d'Alencon. George Bunyard.

Maidstone.

THE BLACK CURRANT MITE.

I was deeply interested in Mr. A. H. Pearson's article on above subject in The Gardeners' Magazine of November 1. If the simple remedy he has discovered proves so efficacious in the destruction of this pest we may soon regard him as a public benefactor. He proves conclusively that he has mastered the pest, and what he has accomplished on so large a scale ought to be an easy matter in smaller gardens.

I have long been of opinion that it is in small and neglected gardens the mite is quite at home, and from these breeding places it is spread broadcast all over the country, so that a garden which is quite immune from attack this year can only be kept clean next year by the use of preventive measures. For the past six years our bushes have been quite clean, but this year we have been disturbed by discovering a crop of big bud on three or four of them. All the other bushes were laden with fruit this summer, but there was absolutely no fruit on the infested ones, because in the previous August they burst into second growth, and buds which ought to have been maturing as fruit buds made two or three small leaves. When pruning, I was harder on these than the rest, but could find no big bud to indicate that the mite was present. I had quite made up my mind to pull these bushes out this season, as they were behaving in the same erratic fashion which forecasted no fruit next season, and during a recent examination I found quite a number of big buds.

When I came here seven years ago I had to clear out the entire lot of black currant bushes, as they were so badly infested; they were promptly burned, and the ground limed and deeply trenched, and limed again on the surface. I made a new plantation in another position altogether, buying in the stock "guaranteed clean," the varieties being Victoria and Boskoop Giant. On delivery I discovered one or two big buds on Boskoop Giant, so this variety was promptly returned and Victoria ordered. Beyond spraying with alkali wash in winter, along with the fruit trees, no other precaution was taken, and every visitor commented upon the clean, healthy condition of the bushes.

My intention now is to consign the infested bushes to the flames, and act on the information given by Mr. Pearson, but, in addition, I shall return to my first practice of spraying with caustic wash in winter. I believe if I had sprayed each winter I might have had a clean stock yet; but I thought after the first two seasons the danger was over, and so stopped spraying. A dry spray of two parts sulphur to one part lime is frequently advocated, and only the other day I visited a large garden where every black currant shoot was greased in winter, and the bushes are entirely free from mite. The enclosed photo is of a mite magnified 4,000 times, but I fear, however, that it is too indistinct for reproduction. [Quite useless for reproduction.—Ed.] James Bethel.

The Grange Gardens, Monfieth.

Cucumbers.—A night temperature of 65 to 68 degrees will now be sufficient for cucumbers, a little ventilation being given whenever circumstances permit. Do not pinch the laterals as previously recommended, but rather encourage a little more extension; be careful not to overcrop the plants, but encourage them by light, rich top-dressings. Syringe the beds and surroundings with tepid water, but overhead syringing should now be discontinued.—F. Jordan, Warter Priory Gardens.

HARDY PERENNIALS FOR GROUPING.

Few plants add so much beauty to a garden as the more handsome hardy perennials, and, in addition to their use in the herbaceous borders, well-arranged groups are a means of greatly enhancing the attractions of the pleasure grounds and wild garden. For this purpose it is desirable to choose the more vigorous species, as they create a striking effect, and readily adapt themselves to the conditions of growth. In most gardens there are positions that could be rendered more picturesque by the planting of large beds and irregular groups of hardy flowers. For example, high ground by the water's edge, and the forefront of shrubberies, could be made bright and gay with waving masses of attractive blossoms.

Suitable plants are very numerous, and among them the delphiniums, with their stately spikes of bloom, form a telling feature. One colour alone may be used in the formation of groups; but large masses, in which different varieties are artistically blended, are equally attractive.

Several of the campanulas are ideal subjects for this style of planting. C. latifolia and the variety alba look charming in the woodland; while C. persicifolia and C. lactiflora are decided acquisitions. Buphthalmum speciosum grows vigorously in moist, rich soil, and its deep yellow flowers make a rich display. Lythrum roseum superbum make a strong growth, and blooms profusely under similar conditions, and associates very well with the above subject. Artemesia lactiflora, with tall panicles of white flowers in late summer, is a delightful subject for the woodland or stream side. Stenantheum robustum is even more attractive, its tall white plumes frequently attaining a height of 6ft., and continue to make a display well into the autumn. Funkia Sieboldi luxuriates in a moist position in partial shade; as also do Ranunculus aconitifolius, with white flowers, and Trollius Orange Globe. During the early part of summer these free-growing subjects make a bright display.

Probably no plants produce a more telling effect than the tritomas; and it is a matter for regret that they do not remain longer at their best. T. caulescens flowers in July, and a large mass of it on a slight incline looks remarkably well; while at other times its yucca-like foliage is distinctly attractive. T. uvaria grandiflora is a splendid variety for autumn effect. Verbascum olympicum is an ideal plant for the wild garden, where it seems perfectly at home, and reproduces itself freely from seeds, rivalling the foxgloves in this respect. Senecio clivorum is extremely effective in large masses near the water's edge; and the newer varieties, S. Veitchianus and S. Wilsonianus, with handsome, erect flower spikes, must on no account be omitted.

The spiræas must not be overlooked, as few subjects create a more pleasing effect, especially near the stream side. Of these, S. aruncus possesses tall, wavy plumes of creamy-white flowers, and is one of the most delightful. S. palmata has spreading clusters of lovely crimson blossoms; and S. venusta has attractive rosy-pink flower-heads. Astilbe Davidi is a charming species, possessing graceful spikes of rosy-purple flowers; and A. Queen Alexandra has deep pink blossoms of a very pleasing shade. A. grandis is a Chinese species, often attaining 6ft. in height, and its pure white flower-spikes are very beautiful. Epilobium angustifolium is well worth a place, as also is Echinops Ritro, with large, globular heads of blue flowers. Lupinus polyphyllus and its varieties are exceedingly showy, and are always admired when growing in large groups. The numerous varieties of Phlox decussata form beautiful objects planted in large beds; and pæonies are equally desirable for this purpose. Helianthus multiflorus and H. rigidus Miss Mellish are valuable for the production of colour effects in the late summer; and a little later on the perennial asters, some of which, like A. Climax, A. Beauty of Colwall, and A. Novæ Angliæ and its varieties, are ideal subjects for this method of arrangement.

Several of the polygonums are extremely handsome when massed, but some of them require unlimited space, as they are more easily planted than eradicated, so rapidly do they increase. P. cuspidatum can be recommended. It produces drooping panicles of creamy-white flowers in great profusion during the autumn, when it is a beautiful object. P. virginianum is an attractive species of medium growth. Bocconia cordata is worth inclusion, but the creamy-white flowers of B. microcarpa are rather more attractive. J. Gardner.

Batsford Park Gardens.

FLOWER BORDER IN A KITCHEN GARDEN,
Composed of Sweet Williams, edged with Viscaria.

Suggestions for Border Planting. — In a recent issue Mr. T. Smith gave some suggestions for planting the margins of fruit-tree and kitchen garden borders with flowers. An illustration of cordon apples bordered with aubrietias has already appeared, and on this page is shown another of the flower-bordered fruit quarters at Coombe Court.

TWO GOOD MELONS.

I should like to bring to the notice of those interested in first-class melons two fine varieties, viz., The Manchester, a scarlet-fleshed variety of all-round excellence, and Sutton's Ringleader, a fine green-fleshed variety. Many good gardeners follow a different method to mine in training and stopping, and they do not allow their plants enough headway. The Manchester requires great freedom of growth, and my method is to stop or pinch the growth at about 15 inches high; then comes four or five shoots, which I pinch again at a foot long, and then obtain seven to ten laterals, which invariably all show fruit. These laterals are not pinched or stopped again until the fruits are about the size of walnuts. If too many laterals develop, I rub out the alternate growths, so as not to have a thicket. When the fruits are as large as a cricket ball, about five or six to a plant, which is a fair average, I rub out entirely all growths not required, but always ensure plenty of strong leaves, without which one can never secure well-finished melons, rich in flavour.

As the fruits show signs of having swelled to their limit of about 5lb. to 6lb., some of the rampant growths and leaves may be thinned, but this must be done gradually. No better compost can be used than yellow fibrous loam, some rotten manure, and a shovelful of soot and lime to each barrowload of soil. I always keep thrips and spider at bay by using plenty of moisture throughout the season of growth. I never allow water to touch the stem, but frequently dust a little dry lime round the collar of the plant to prevent canker. I do not rub out the male flowers, as many do. I advise growers to try these two varieties—The Manchester, scarlet, and Sutton's Ringleader, green. Give them freedom of growth and they will be free growers, free setters, handsome in appearance, rich of flavour, and always winners at the shows, at least I have found them so under these conditions. W. Irvine.

St. James' Gardens, West Malvern.

PLANTS FOR THE MORAINE.

More and more does the value of the moraine for the treatment of alpine flowers become apparent, and it is evident that the moraine is the key to the successful cultivation of many choice plants in our climate. In the moraine many of them will laugh at the assaults of both excessive rainfall and extreme drought, and will give results unattainable in any other way. The moraine need not be an elaborate one, and much needless elaboration is often followed in its formation. The main feature is the good layer of gravel or chips above, and ample drainage below. In the following notes only good plants which have been carefully tested are named.

Dianthus Spencer Bickham.

This choice little hybrid pink is absolutely happy in the moraine, and it is increasing more rapidly than one could persuade it to do in the ordinary treatment of the rockery. I have a charming little plant of it here in a moraine composed of whinstone chips, with a very large proportion of old mortar and lime rubbish. Indeed, one has transposed the ingredients; for the bulk is lime rubbish and old mortar. Only about one-third is whinstone chips. Here Mr. Spencer Bickham's pink is flourishing, and in summer was a perfect beauty with its little stems three or four inches high, bearing such dainty little crimson flowers.

Thymus micans.

Under this name there is a delightful small thyme, which is pretty in the rock garden, but is still prettier, and does even better in the moraine. A little bit taken off a plant in the rock garden and planted in a whinstone and lime moraine (the proportion here being about one part of whinstone chips to one of old mortar and lime rubbish) has thriven exceedingly well, and has formed a dainty mound of vivid green decorated for a long time with tiny pink or purplish flowers. I see that the great "Index Kewensis" refers T. micans to T. serpyllum, but, though it may be nearly related, the plant I have as T. micans is totally unlike our common thyme. It has very small foliage, and forms a mound almost like one of moss. The moraine seems, however, to be congenial to the thymes, for in the same moraine a little bit of T. s. lanuginosus has also made itself thoroughly at home, and is, indeed, spreading too quickly. T. micans, however, though growing rapidly, has not the rampant growth of T. serpyllum and its varieties, and is a most exquisite little alpine, and perfectly hardy.

Æthionema iberideum.

The æthionemas are evidently happier in the moraine than anywhere else, and Æ. iberideum, the iberis-like one, is one which is making itself thoroughly at home in the same moraine as the tiny Thymus micans. A small plant has soon made itself quite happy there, and is growing remarkably well. It is a white-flowered species, and gives a number of heads of flowers which are pleasing in the mass. Against the grey moraine the glaucous foliage looks quite harmonious, while the silvery flowers appear entirely in consonance with the chips and lime granules. These æthionemas delight in free drainage, so that they settle themselves well down to the conditions of a moraine.

Saxifraga paradoxa.

Everybody who loves the silvery saxifrages (and no true alpine grower is without the number) will seek to give these beautiful flowers the conditions under which they look best and are happiest. Speaking theoretically, most of these silvery saxifrages should thrive best with some lime in the compost or moraine, but I find that my finest plants are in a moraine which has no lime about it. Perhaps, after the others have been as long in the lime moraine they may give as good results, but they hardly look like it, and it is impossible to conceive prettier and more charming silver saxifrages than those which have been tried in the pure whinstone moraine. Among these is that charming one called in gardens S. paradoxa. Authorities tell us that it is a variety of S. aizoon, but I am disposed to agree with the eminent writer who says that he "cannot see by what right the plant dares to call itself an aizoon at all." Still further, I agree with him in saying that it has "the loveliest foliage of the whole race." The same writer, by the way, asserts that it has the poorest flowers. I think I know of some with poorer flowers, but, all in all, S. paradoxa is a rarely beautiful plant, and it seems greatly glorified in the moraine. It thrives better there than on the rockery, and is a gem indeed with its long, blue-grey, silver-edged leaves. Against the grey of the whinstone it is a picture of the rarest beauty.

Androsace Chumbyi.

I suppose, if we follow the Kew "Handlist," we must call this delightful plant Androsace "sarmentosa x villosa," but nobody would care to talk familiarly of a flower with such a name, although I suppose it is doubtless a correct indication of its lineage. But "Chumbyi" it is likely to remain, and as Chumbyi I shall speak of it. A little plant was committed to the lime and whinstone moraine (the first one mentioned in these notes), and there it has thriven splendidly. It has given me many of its heads of lovely rosy flowers above the silvery rosettes. Compared with its sisters in the rock garden, this plant surpasses them all, and shines pre-eminent as the prettiest of the bevy of beauty.

Just a word as to planting these in the moraine. I like to plant them with a modicum of soil about the roots, so that they will suffer little at first from being consigned to the chips without a little root-hold. They soon establish themselves, and are then independent of the soil until they reach down to the earth below.

S. ARNOTT.

Broad Beans.—Where no convenience exists for raising the plants under glass early in the new year, a sowing outdoors may be made forthwith; the position must be warm and sheltered, and the soil well drained. To preserve the seeds from rotting place in the drills a layer of finely-sifted leaf-mould, and cover the seeds with a further three inches of the same or a mixture of finely-sifted potting-bench refuse and leaf-mould. The seeds may be sown thickly, and the surplus plants transplanted in February or March. Royal Dwarf Cluster and a good type of Longpod are suitable varieties for present sowing.—W. MESSENGER.

SPIRÆA ARBOREA.

Spiræa arborea is a Chinese species, belonging to the Sorbaria group—Sorbaria being an old generic name which numerous present-day botanists are reviving. The group also includes S. Aitchisoni, S. assurgens, S. Lindleyana, and S. sorbifolia. S. arborea (Schneider) is a very variable species, and two or three forms have been given varietal names, but connecting these are numerous intermediate forms, making it difficult in some instances to say to which variety a particular plant belongs.

They are all vigorous-growing shrubs, seven feet to eight feet or more in height, with elegant pinnate leaves, consisting of, usually, seven or eight pairs of leaflets. Allied to the Hamalayan species, S. Lindleyana, they differ in having the underside of the leaves more of less tomentose (except in the variety glabrata), the magins of the leaves less deeply serrated and longer stamens; the inflorescence is also tomentose. In the variety sub-tomentosa, introduced by Mr. E. H. Wilson from China, the woolly character of the leaves and inflorescence is less marked. A second variety, glabrata, also introduced by Mr. Wilson, has glabrous foliage, and a narrower inflorescence with ascending branches.

The typical inflorescence of S. arborea is inclined to be flat-sided, and roughly triangular in shape, 12 inches to 15 inches long, and 9 inches to 12 inches wide at the base. S. arborea var. grandis, given an Award of Merit by the Royal Horticultural Society on July 29 last, and figured in THE GARDENERS' MAGAZINE the following week, has white flowers, and is another of Mr. Wilson's introductions from China. The several varieties flower throughout the month of July, and most of August.

A. O. K.

THE CHICKWEED FAMILY.

It will probably surprise a good many of my readers who are only too familiar with the common chickweed as a remarkably intrusive garden pest, that it really belongs to a family to which we are indebted, as a counterpoise, for many beautiful garden gems. Among these, as species of the same order, are the dianthus tribe, embracing all the beautiful pinks, from the little alpine gems which render our rockeries resplendent in the early summer, to the magnificent carnations which form so important a cult in themselves as to constitute a basis and raison d'être for a number of societies all over the world in temperate regions.

The extremely beautiful silenes, arenarias, and lychnis of many kinds are also relatives, and at the moment of writing we have in sight another relative in the shape of a double form of saponaria, which like its relation, the chickweed proper, has an invading character, owing to its underground stolons, but in due season pays its rent to the full by forming a huge mass of rosy-pink double flowers of great beauty, borne on lax stems rising a foot or more from the soil.

Of the natural order Caryophyllaceæ to which the chickweed belongs there are about 60 genera, and over 1,000 species. Though these are found spread all over the world, they are practically confined to high and cool elevations in the Tropics, or to regions of moderate temperature, their consequent hardiness being thus greatly in their favour as popular garden favourites.

C. T. D.

CHOOSING APPLES FOR PLANTING.

It is so difficult in gardening to lay out one's money to the best advantage that probably no one, not even the most careful man, avoids buying things sometimes which turn out to be unsatisfactory. Even if our judgment is perfect, and our nurserymen such us exactly what we ask for and nothing else, there is always the great uncertainty as to how our soil and general conditions will suit the plants, trees, etc., which we buy. Choosing varieties of apples is by no means one of the least difficult in this respect, and no amount of advice can altogether guarantee us against mistakes. Still, there are often certain well-defined causes underlying one's failures, and these may serve as warnings to intending planters. The form of tree to be planted must depend upon one's circumstances, while the choosing of trees, of whatever form, is a general subject, and does not specially relate to apples, so that neither of these subjects will be touched upon here.

The exhibition table is one of the most common pitfalls for intending planters, and for others as well, for it is there that we are led to choose varieties solely on their appearance, without knowing anything of their hardiness, fertility, and other characteristics which will determine their success or otherwise under our conditions. The apple behaves most inexplicably in various soils and situations. I will not say it is capricious, for I am doubtful if any tree or plant is really that in the way we apply the word to individuals, though we often apply the term to plants when we do not understand the cause of their failure. Not only will the same variety of apple grow and fruit well in one place and badly in another not far off, but in the one case it may be a good dessert variety and in the other a very poor one. As an instance, that apple which some of us praise so much, Egremont Russett or Petworth Nonpareil, was said by a writer in a gardening paper recently to be not worth eating with him.

Assuming that we have a definite idea for what purpose we want apples—early, mid-season, late, dessert or cooking, etc.—the great desideratum is to find out what sorts are best adapted to our conditions. Market growers have been recommended to plant two or three trees of a number of varieties with the idea of finding out which do best on their land, and then to plant their ground with trees of a few of the most promising of them, and no others. Most of us, both amateur and market growers, plant too many sorts. In some of the famous apple-growing districts of the Western States only one or two varieties are grown, and in some parts only one, that is, on a commercial scale, apart from the needs of inter-pollination.

For the private grower, who wants to plant a few trees only, it is often difficult to find out which of the varieties that meet his requirements are likely to do best with him. The best thing he can do is to consult his neighbours as to those which are the greatest success with them, and, if any of those varieties are adapted for his purposes, to plant them. There is often, however, a considerable difference in soil conditions within a couple of hundred yards. Most of us want to plant certain varieties, e.g., Cox's Orange Pippin, whether suitable or not, and in these cases we have to learn by experience. I have seen healthy young trees of this variety literally crack to pieces after a couple of years. Catalogues are not as a rule of much use to us in this respect, for they recommend all the varieties included, but rarely mention any unfavourable characteristics, of which probably every variety grown possesses at least one.

There are one or two general principles we might bear in mind. If our situation is more than ordinarily liable to late spring frosts we should try to avoid those varieties which flower early. There is fully a week between the very early-flowering varieties, and the mid-season ones, and nearly another week between the latter and those which flower very late, so that there is enough scope to make all the difference between probably losing the crop through frost and being fairly safe. The "Journal" of the Royal Horticultural Society for December, 1911, gave some valuable information on this subject.

Then, again, if the soil is a damp one, especially if it is very fertile, this is favourable to late vegetative growth, which means that fruit will keep on growing in the autumn instead of maturing, or "finishing," as fruit growers call it. This is fatal to the late varieties, dessert especially, as they will only properly ripen under such conditions in an exceptionally favourable season. After the memorable summer of 1911 it would have been thought that all varieties would mature, but on a wet soil Sturmer Pippin was not ready to gather at the end of November, and, though there was some fine fruit to all appearance at the time of picking, a considerable percentage shrivelled so much as to be worthless for dessert. Duke of Devonshire behaved similarly. On such a soil it would not be advisable to plant varieties which are specially liable to canker.

But when we have used all the care and forethought of which we are capable, and have consulted all friends and neighbours, we shall still probably plant some varieties which will not be a success, but we shall have reduced the number of failures to a minimum. There is always some mysterious factor which causes some excellent varieties to come much below our expectations. It is not always either the soil or the climate, for there is no doubt that with many varieties, there are a number of strains which have arisen from what is known as "bud variation." The most casual observer, when visiting a large fruit show, must have noticed the difference, often very considerable, in the appearance of Blenheim Pippin, for instance, and if he has had the opportunity of eating this same variety from several trees year by year he will probably not have failed to notice similar differences in the texture and flavour, even though the characteristic flavour of the variety is not altogether absent from any—the points of variation being so constant year by year that he can often tell from which tree, or from whose garden, a particular fruit was gathered. This is a subject to which more attention is likely to be given in the future, and one which fruit growers cannot afford to ignore if they are going to compete successfully in the markets of the world.

ALGER PETTS.

APPLE HITCHIN PIPPIN.

An excellent dessert variety, somewhat similar to the King of the Pippins.

APPLE HITCHIN PIPPIN.

This is a dessert apple which not a few growers speak highly of, and one which has been frequently exhibited during the last two or three years. It is a free grower and regular cropper, and bears fruits which have a very close resemblance to those of the old and well-known King of the Pippins. In flavour it is superior to the older variety and keeps well. Where a substitute is needed for King of the Pippins—and it is common knowledge this variety does not please every fruit-grower—then Hitchin Pippin may well be cultivated. Our illustration shows a fruit exhibited not long since by Messrs. George Bunyard and Co., Maidstone, in a large basket of this variety.

THE COTONEASTERS.

Until the present century the headquarters of the genus Cotoneaster were considered to be in the Himalaya, but recent explorations in Central China have revealed so many new species that it is probable the former country will have to relinquish its claims in favour of China. The genus is an important one to horticulturists, for it contains many species which bear attractive fruits, some being, at the same time, useful evergreens, and pretty flowering shrubs. In addition, the genus is an accommodating one, for it includes plants which exhibit a wide range of habit, from prostrate shrubs, rising but a few inches above the ground, to those of tree-like dimensions.

Some kinds, such as C. horizontalis, C. microphylla, and C. thymifolia, are excellent for planting on rockeries, whilst they may be planted against walls with equally satisfactory results. It is astonishing how well they adapt themselves to the latter method of culture, for, while being semi-prostrate bushes, when planted in the open ground, they grow to a height of twelve to eighteen feet against walls, and attain that size with little aid from the gardener. They thrive most satisfactorily in loamy soil, and prefer that of a medium consistency to that of a clayey nature. But they also do remarkably well in light, sandy soil. The greatest difference, perhaps, between plants growing in poor and really good soil, after allowing for the difference in vigour, is that the leaves of some deciduous kinds growing under the latter conditions are retained later in autumn than in the case of plants growing on sandy ground, greater vigour, in some cases, allowing the leaves to be carried until well on towards Christmas. Temperature, also, exerts a distinct bearing upon the fall of the leaves, and when a very mild autumn and winter is experienced, some kinds which would otherwise be deciduous retain their leaves almost until new ones appear.

Seeds of most of the kinds are ripened freely, and they form the most satisfactory means of propagation for the more vigorous kinds, but the dwarf set may be grown quite as well from cuttings of short, half-ripe shoots inserted in pots of sandy soil in a close frame during July or August, or, if large numbers are required, they may be dibbled into a bed of sandy soil in a cold frame. Formerly the practice obtained of grafting various species upon stocks of common thorn. Fortunately, this method of propagation has been discarded in the best gardens.

Little in the way of regular cultural attention is required by the cotoneasters. Except when growing under conditions which necessitate the restriction of growth, they require no regular pruning, providing attention has been paid to procuring a stocky foundation during early life. People sometimes like to have examples of the strong-growing C. frigida with a distinct trunk, and in such cases it is necessary to trim the lower branches off, or shorten them, in order that the full strength of the plant may be centred upon a single stem.

W. DALLIMORE.

(To be continued.)

COLOUR SCHEMES IN GARDENS.

As a general rule it is as desirable to provide contrasts as well as colour harmonies in the garden, and where space is limited, the use of one colour with its many shades passing gradually from the palest to the deepest hue, does not provide the greatest enjoyment. On the other hand in large gardens such schemes have much to commend them, and, if well carried out, they provide items of great interest. It must be admitted, however, that an ambitious programme in this direction is likely to prove rather costly, both in labour and material; but where there are gardens within the garden, then one may be devoted to blue, another to yellow, and another to red flowers; or grey-leaved plants may be pressed into service in yet another. At Friar Park, Henley, Sir Frank Crisp, Bart., has, as readers are aware, a large number of special attractions as well as the general one which always attaches to a well-kept garden. Quite recently we referred to the Fragrant Garden there, and now, while planting is still in full swing, the grey and blue gardens are worthy of note, and are herewith illustrated.

THE GREY AND BLUE GARDENS, FRIAR PARK, HENLEY.

Polygoniums, santolinas, cerastiums, echeverias, and many other plants are available for a grey garden, while for the blue quarters there is abundant available material, ranging from tiny campanulas up to tall anchusas and giant delphiniums. Grey-leaved plants are not so numerous, or, at least, not so well known, and it would therefore prove an interesting and pleasant task for younger readers among professional gardeners to make a note of suitable species and varieties which they would select if commissioned to plant a grey garden or a grey border. Having completed their task, we should like to receive a copy of the list.

FUNKIA TARDIFLORA.

This attractive plant is well named, for it is the latest of all the Plantain Lilies to flower. The first blooms do not expand until September, while in favourable seasons the period of flowering extends, as this year, well into November. It is of Japanese origin, a plant having been found in a collection of funkias brought back to America from Japan by Mr. Thomas Hogg about 1870. Being distinct from anything already in cultivation it was named and distributed as Funkia Thomas Hogg.

A plant under this name was obtained from America by Mr. Max Leichtlin, of Baden Baden. He did not like the American title, and appropriately substituted the name of F. tardiflora. Kew obtained a plant from M. Max Leichtlin in 1895, and inches to 18 inches in length, and freely furnished with lilac-tinted blossoms.

Division of the clumps forms a ready means of increase, the best season for the work being March and April. Such a good flowering plant as F. tardiflora is worth cultivating in pots for cool greenhouse and conservatory decoration. Under glass the prettily-tinted flowers, with the protection afforded, are very useful at a season not abundantly supplied with dwarf flowering plants for the side stages.

Kew. A. OSBORN.

PÆONY-FLOWERED DAHLIAS

At the second of the September and the first of the October exhibitions held by the R.H.S. at Vincent Square, these flowers were shown in great numbers, and it is almost a

CAMPANULA PROFUSION.

This charming alpine Bell-flower greatly resembles one called C. haylodgensis, raised by the late Mr. Anderson Henry, at Hay Lodge, Edinburgh, and also one which is now called C. Tymonsi, but which is not, I think, the C. Tymonsi originally sent out. It is, however, a plant raised distinctly by a well-known hardy plantsman, Mr. E. H. Jenkins, of Hampton Hill, one who knows hardy flowers better than most, and who has, fortunately, preserved the origin of this hybrid Campanula. It was obtained when Mr. Jenkins was trying to cross C. pyramidalis alba with C. turbinata var., and the seed-pod was actually taken from the former. The result is rather a curious one, as the little campanula under notice bears no trace of either of its parents.

FUNKIA TARDIFLORA.

A beautiful Plantain Lily, producing its lilac coloured flowers in late autumn.

a considerable number of plants having been propagated, we have a good show when they flower during the autumn. Flowering at a season when frost may be expected, it is as well to select slightly sheltered spots for this funkia, and it is well known that all the Plantain Lilies thrive in moist, partially shaded positions, and some of the best plants at Kew are in the Bamboo Garden. It is also used as a carpeting plant for beds of deciduous shrubs and in the Rock Garden.

Funkia tardiflora is allied to F. lancifolia, and has, in fact, been referred to as a variety of that species. Its more tufted growth, shorter and more crowded racemes of flowers, and late season of flowering, should be ample distinctions for its consideration as a distinct species. The dark green, lanceolate leaves are comparatively short for a funkia. The racemes are 12

mystery how they have gained so much popularity and seem to hold a higher position—in many people's estimation—than the cactus-flowered varieties. I do not for a moment suggest that the colouring in this section is poor; in fact, in this respect everyone will, I think, agree that they are a great acquisition to a garden for late summer and autumn flowering. The weak feature, in my opinion, is the badly-formed centres of so many of the pæony-flowered varieties. If these flowers could be grown with a decided "eye," or else with a quite uniform centre, the flowers would be, I think, very much more attractive.

As it is now, one sees flowers shown which strike one as being mere freaks, and were it not for their colour one would feel disposed to discard them altogether. How is it that this point is overlooked in this one class of dahlia? If a cactus bloom is shown with the least flaw it is rejected at once. Why should not the same apply to these? L.

However this may be, the plant is a delightful one, of trailing habit, and with yellowish foliage, and bearing pleasing, light-blue flowers. This is the form generally seen, but, as a matter of fact, there are two forms of C. Profusion, one with yellowish and the other with green leaves, just as there are two varieties of C. G. F. Wilson, presenting the same points of difference as are shown by these two Profusions.

I look upon C. Profusion as one of the prettiest and best of our hybrid Campanulas, and, as it is not difficult to grow on the ordinary rockery, it should be acquired by the many. It seems to prefer a little shade, but is not too particular. C. Profusion is increased by careful division in spring or summer, and also by cuttings taken in summer and autumn. It flowers from June onwards. S. A.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

WINTER-FLOWERING CATTLEYAS.—In many private gardens there is considerable demand for attractively-coloured flowers during the months of November and December, and if decorations consist of a limited class of any kind of flowers for a lengthy period complaints are apt to be made. Things are very different now to what they were a decade ago, and there is as great a demand for change in floral arrangements as in other pleasures of life. While we may obtain considerable variation in tints among florists' flowers in general, the colours are limited, but we find among the autumn and winter-flowering cattleyas those tints of colour which are particularly pleasing. There need be no extensive outlay where there is a stove house, as it will afford facilities for the cultivation of most of the winter-flowering cattleyas.

C. LABIATA is one of the most serviceable for the purpose, and as plants are annually imported in large quantities, and are procurable in an imported state for a modest outlay, there is no difficulty in obtaining good stocks. They are exceedingly free-flowering, and if procured early in the year they bloom the following autumn. Like many other imported species they grow and flower well for a few years, but their free-flowering habit will in time cause a general deterioration. It is therefone desirable to add a few imported plants to the collection each year. C. Harrisonianum and C. Loddegesi, with their long spikes of flowers, are also most useful, and where suitable conditions are provided the plants retain their normal vigour for an indefinite period. C. Bowringiana is another species that does well in cultivation. C. aurea and the natural hybrid C. Hardyana are also desirable.

AMONG THE HYBRIDS, C. Mantini, C. Wendlandi, and a whole host of others that have been derived from the use of C. Bowringiana as one parent, are of much value. We have also large-flowered kinds of great excellence as C. Fabia, one of the most variable of all cattleyas; Lælio-cattleya Bella, and the numenous hybrids from C. labiata. The greatest variation and certainly the attractive colours are found in hybrids that have been raised from C. aurea or C. granulosa. The varied tints of orange, scarlet, and yellow among the later introductions have added to the charm and usefulness of the autumn-flowering cattleyas. I have wandered from the beaten path in this issue to draw attention to the utility of a class of plants that cannot fail to be serviceable to my brother gardeners, where the autumn requirements are a great consideration.—H. J. CHAPMAN, Oakwood Gardens.

STOVE PLANTS.

THE PALM HOUSE.—The present season affords an excellent opportunity for thoroughly overhauling the house devoted to palms, which, in common with all plants growing inside, cannot give of their best unless both the plants and the house in which they are growing are kept in a clean condition. The leaves should first be loosely tied up to avoid injury when the plants are being moved to one end of the house while the vacant half receives a thorough cleaning. Glass, woodwork, and walls should be washed down with warm soapy water containing a little paraffin or other insecticide, the walls limewashed, and the granite chips or material on which the pots stand be washed or renewed. Afterwards remove the plants to the clean half whilst the other section is similarly treated. The plants should now be thoroughly cleaned, scale being the most troublesome pest, and where this is present great care will be necessary to remove it without damage to the fronds. This, however, may be accomplished by means of a sponge, or small brush, with a little insecticide. Thrips are sometimes troublesome, but an occasional fumigation will keep them in check. Red spider is also a visitor, but usually only when proper care with regard to damping and watering has been somewhat neglected. The plants should now be rearranged, and where considered necessary the soil in the pots may receive a slight topdressing of soot and bone-meal, or other approved fertiliser. Imperfect drainage may be attended to, but repotting had better be deferred until the early spring. Watering should be accomplished with care, for palms generally suffer when the moisture about their roots is in a stagnant state during the winter months.

BULBS, CORMS, AND TUBERS.—Having been stored for their resting season, these should, if time permits, be examined. Caladiums are generally kept in good condition undisturbed in their pots in a temperature not lower than 60 deg., but there is always the possibility of their being damaged, either by being in too close proximity to the hot water pipes, or by the soil becoming wet through drip. Achimenes that were stored with any growth remaining should now have this removed, as also should gloxinias, afterwards replacing them in the resting quarters. Amaryllis should be examined and cleaned. Some of the earliest will probably be found throwing up their flower spikes. These may receive a thorough soaking prior to being top-dressed, and be placed in a warm house, to form the earliest batch. Flowering in the winter these will prove most acceptable for decorative purposes. Calla Elliottana should be sufficiently ripened to store in the pots in which they have been grown until required in the spring months for restarting. —H. PRIME, Hatfield House Gardens.

THE FLOWER GARDEN.

THE WATER AND WILD GARDENS.—Now is an opportune time for giving special attention to the water garden and wild garden. In the wild garden many of the occupants are of herbaceous character, consequently their foliage is now in a state of decay, and should be cut off and cleared away, as most of that which was retained for its autumn colouring is no longer attractive. At the same time fallen leaves and rubbish can be collected. Then fork up the soil round about the shrubs and plants as deeply as possible without injuring the roots, at the same time working in some well-rotted manure or leaf-mould, the latter, preferably on stiff ground. No trouble should be spared as the work proceeds to pick out the roots and underground stems of perennial weeds. Subjects not perfectly hardy should be afforded some protection; lay dry material over the surface soil around gunneras, and cover their crowns with heather or their own foliage, and they will then be safe from the severest frost. Bamboos which have their roots protected by a covering of dry leaves or bracken are not liable to suffer to such an extent during a hard winter as if they are neglected in this respect; it is surprising the amount of frost well-matured growths of many of the bamboos will stand when provision has been made to exclude frost from their roots. Kniphofias, too, are uncertain subjects in some soils, and a covering of dry pine leaves placed round them will keep them safe during severe weather. Mulching the various plants in the wild garden with manure at this season is not to be recommended: such treatment is better deferred until the spring. The foliage of many water plants will now be decaying, and an effort should be made to clear it away.

CHRISTMAS ROSES.—Varieties of Helleborus niger are now beginning to bloom profusely and are well worth a little attention. Afford the flowers some protection from inclement weather, but in such a manner as to avoid coddling, otherwise premature growth will be excited. Cloches or handlights raised on bricks answer admirably for individual specimens, and for quantities growing closely together on a border, lights supported on a temporary framework and made secure against winds, will be found most suitable.

SPECIMEN PLANTS in ornamental tubs and vases, such as myrtles, camellias, bays, hydrangeas, chamærops, etc., used for terraces should be given some shelter from severe weather. If room can be found for them in a well-ventilated, unheated house, no place will be more suitable; failing this, a light, airy shed, or a verandah in a sheltered position, forms a useful substitute. All statuary and other garden ornaments liable to be affected by frost should either be removed to a shed or be covered up with mats or canvas; fountain basins must be emptied regularly after heavy rains, unless constructed of very durable material, otherwise they are liable to become split or distorted.—T. B. FIELD, Wych Cross Place Gardens.

FRUITS UNDER GLASS.

EARLY PEACHES.—Where very early forcing is contemplated, whether of pot or permanent trees, no time should be lost in clearing the orchard house of chrysanthemums or other plants and placing the trees in position. Select those trees well set with buds thoroughly ripened in moderately sized pots that are full of roots and well drained. Only such varieties as Cardinal and Early Rivers nectarines, with Duke of York peach, need be started yet; allow them plenty of time, and start with a low temperature and plenty of ventilation. Mild bottom-heat is a great help, and this may be secured by standing the trees on inverted pots with a good body of leaves around them. Very little pruning is necessary. Some of the strongest shoots and leaders may be cut back to a triple bud, but weak shoots are better left until the young growths are pushing freely.

PERMANENT TREES.—If ripe peaches are required in May, the houses must be closed. Carefully examine the borders and make sure they are in a moist condition down to the drainage. For some time after the house is closed it will not be necessary to apply fire-heat, but as a free circulation of air is most important, it is better to warm the pipes a little, rather than have a cold, damp atmosphere. Flowers expand stronger with free ventilation than where they do not receive this attention early. A temperature of 40 to 43 degrees is high enough to start with, and as the buds swell 45 degrees may be given, rising to 55 degrees during the day with sun-heat.

CHERRIES AND PLUMS.—If these are required early the trees may be at once placed in position; both are, however, most impatient of fire-heat, or of being kept too close. During moist and mild weather full ventilation may be left on night and day. Provided there are shelves in this house, it will be found most suitable to start strawberries in, as the temperature through the first stages need not exceed 40 to 45 degrees by night, and 50 degrees throughout the day.

FIGS.—These should be started for early supplies, and here also gently fermenting material is of great assistance. The temperature of the pit or house may range from 50 to 55 degrees, with a little ventilation on all favourable occasions. Syringe with tepid water early in the day, so that the trees may be dry by nightfall. Avoid hard firing, and if severe weather sets in, let the temperature decline a few degrees.—F. JORDAN, Warter Priory Gardens.

EXHIBITIONS AND MEETINGS.

Liverpool.

NOVEMBER 12 and 13.

The thirty-fourth autumn exhibition held by the Liverpool Horticultural Association adds another to the long list of successful shows. This most recent success certainly surpassed all previous efforts so far as chrysanthemums are concerned, whether as plants or cut flowers, while the exhibition as a whole eclipsed in magnitude all held during recent years. The difficulty was to find space for the exhibits, even when the smallest amount of space allowable was left for the visitors.

CHRYSANTHEMUMS IN POTS.

Liverpool has always come out well in this section, but this season a record was created both as regards quantity and quality. For three large flowering plants, Mr. W. Wilson, gardener to Walter Cunningham, Esq., was to the fore with well-trained examples, carrying a large number of excellent blooms; Mr. T. Hitchman, gardener to A. Earle, Esq., was a close second; and Mr. W. Scott secured the remaining award. In the class for one large-flowering plant, Messrs. Hitchman and Wilson reversed positions. For three singles, trained, Mr. Wilson was in splendid form with Annie Street, as nearly perfect as possible, with flowers of glowing colour; Mr. Hitchman was second. For one pompon, Mr. Wilson was again in the front place with an excellent trained plant of William Westlake.

The class for six singles, staked, not disbudded, found Mr. F. C. Keightly, gardener to Mrs. Duncan, first, with finely-grown plants; Mr. T. Hitchman had the best three, and Mr. E. R. Finch the best single specimen.

Mr. G. Osborne, gardener to Messrs Tisdall and Ingall, and Mr. F. Atkin, gardener to T. W. Wright, Esq., divided the honours for a group arranged on 60 square feet of space.

CUT BLOOMS.

These still claim the chief interest, and, as Mr. N. F. Barnes remarked at the luncheon, if they become much larger, both boards and hall will have to be extended.

In the class for thirty-six blooms, eighteen Japanese and eighteen incurved, Mr. C. Goves, gardener to Sir Gilbert Greenall, repeated his last year's success, so that the handsome trophy now becomes his own property; his blooms were a distinct advance upon those of former years, and included W. Turner (which secured the N.C.S. Certificate as the best Japanese bloom in the show), F. S. Vallis, W. Mease, Alice Lemon, Frances Joliffe, Bob Pulling, Mrs. A. E. Roope, Mrs. G. Drabble, and Fred Green; incurved, G. F. Evans (N.C.S. Certificate), Pantia Ralli, Doris Rayner, Godfrey's Eclipse, Mrs. P. Wiseman, and Embleme Poitivine. The remaining awards went to Mr. G. Haigh, gardener to Sir W. H. Tate, Bart.; Mr. H. Osborne, gardener to Thomas Woodsend, Esq.; and Mr. John George, gardener to Thomas Henshaw, Esq.

For twenty-four blooms, twelve Japanese and twelve incurved, Messrs. C. Goves, J. George, and G. Haigh, were placed as named. For twelve incurved, Mr. J. Young, gardener to W. E. Willink, Esq., led the way, and J. Copple held first place for six blooms. Mr. J. Copple, gardener to H. Belk, Esq., took the lead for twelve Japanese varieties, as he also did for six blooms.

In the class for six vases of singles, six blooms in each vase, Mr. P. Caunce, gardener to G. Nicholson, Esq., won with a surprisingly fine set, remarkable for size and colour; the varieties were Mrs. William Street, Edith Pagram, Ruby, Miss Annie Street, Mrs. H. Herbert, and Miss K. Wells; Mr. Leo Thomson was a close second, staging very fine flowers of Sandown Radiance; Mr. J. Williams was third.

A display on a four feet run of tabling provided a new feature, and Mr. E. Wharton, gardener to J. Findlay, Esq., led with a bright array, in which he introduced the rarely seen anemone varieties; Mr. Haigh was second, and Mr. J. Aindow third. For a basket of blooms, Mr. J. Williams, gardener to C. H. Procter, Esq., proved the winner, and Miss Newsham upheld her fame in the decorated table class, while Mr. J. Shepherd scored for buttonholes and sprays.

MISCELLANEOUS PLANTS.

For three stove or greenhouse ferns, Mr. J. McColl, gardener to J. W. Hughes, Esq., won with a set which included a fine plant of Polypodium knighti; for a single specimen the same exhibitor scored with a grand plant of Gonophlebium subauriculatum, carrying fronds 9ft. long. For three orchids, Mr. Hurd, gardener to L. G. Pilkington, Esq., took the lead; and for one plant Mr. H. Osborne won with a good Cattleya Portia carrying thirty-seven flowers.

For a pair of palms or cycads, Mr. F. Atkin, gardener to J. W. Wright, Esq., led with grand kentias, following this up with the best three palms in eight-inch pots.

Mr. E. Wharton came out first in a strong competition for four begonias with excellent plants. Mr. H. Holland, gardener to Mrs. J. D. Lever, had the leading cyclamen in two classes.

FRUIT.

This section was hardly up to Liverpool's standard, colour being below the average in grapes, apples, and pears. For six dishes, distinct, dessert fruits, Mr. T. Elsworthy, gardener to W. L. Gladstone, Esq., was to the fore. For four bunches of grapes, Mr. J. Wright, gardener to Edmund Lord, Esq., led with Muscat of Alexandria and Alicante; Mr. T. Barclay second with good Muscats. Mr. W. Wilson was to the fore for two bunches of Alicante, and for two of any other black grape, Mr. W. H. Faulkner, gardener to A. P. Eccles, Esq., scored with Gros Colmar, fine in berry and bunch. Mr. W. Wilson showed the best two bunches of Muscat of Alexandria.

For six dishes of dessert pears, Mr. J. Lee scored with weighty fruits; Mr. F. C. Keightly had the leading four dishes, and Mr. Lee the best single dish, showing good Doyenne du Comice. Mr. J. Bott won for six dishes of dessert apples with handsome fruits, and scored for one dish with Cox's Orange Pippin. Mr. Bott had also the best six dishes and single dish of culinary apples.

NON-COMPETITIVE.

The association is much indebted to the trade for their assistance, and possibly this has never been given more generously than on this occasion.

Gold Medals.—To Messrs. Stuart Low and Co., Enfield, for a fine display of carnations, a Certificate of Merit being awarded to Gorgeous, a bright scarlet variety of good size; this firm also staged orchids; to Messrs. Mansell and Hatcher, Rawdon, for a grand array of orchids; to Messrs. Fishlock Bros. for an extensive contribution of floral designs.

Silver Medals.—To Messrs. W. Wells and Co., Messrs. W. Rowlands and Co., and Messrs. Dicksons, for chrysanthemums; to Messrs. Young and Co., Hatherley, for carnations; to the Liverpool Orchid Company, for orchids; to Mr. J. W. Fletcher, gardener to R. le Doux, Esq., for orchids; to Messrs. R. P. Ker and Sons, Aigburth Nurseries, Liverpool, for cyclamen.

Awards of Merit.—To Messrs. Clibrans, Altrincham, for chrysanthemums; to Mr. H. Middlehurst, for vegetables; to Messrs. T. Davies and Co., for heaths; to Mr. C. A. Young, for carnations.

Reigate.

Reigate held a splendid autumn exhibition in the Public Hall on November 12, but, alas, the hall, with the various downstairs rooms, does not provide sufficient space, or the right kind of space, for the proper display of such numerous and high-class exhibits. The committee works most enthusiastically and pleasantly, and has worked wonders in recent years, so that now there is not only a fine exhibition annually, a large number of cups and trophies for competition, but also a balance on the right side, and a small reserve fund. Probably in the near future a more suitable hall will be secured for the show, and then the efforts of the Reigate Society will be better appreciated.

CUT FLOWERS.

The silver cup presented by Miss Wooley for the best twenty-five Japanese blooms, distinct, shown in five vases, was won by Mr. H. G. Bassett, gardener to Mrs. T. B. Haywood, Woodhatch Lodge, whose examples of Mrs. G. Drabble, F. S. Vallis, W. Mease, Reg. Vallis, Queen Mary, W. Turner, Mrs. Drexel, and T. Lunt were of capital size and finish; Mr. W. Morgan, gardener to W. Ellis, Esq., The Woodlands, came second with smaller but quite fresh flowers; and Mr. T. Beeson, gardener to Mrs. N. Mappin, Headley Park, Epsom, came third; four entries.

Mr. C. Fox, 12, Linden Gardens, Tunbridge Wells, led for ten Japanese blooms staged in two vases, and he was followed in order by Mr. H. G. Bassett, and Mr. S. W. Sherlock, gardener to G. W. Tyser, Esq., J.P., Oakfield, Morden. In another and similar class Mr. Fox was again premier prizewinner, with Mr. E. W. Walker, 30, St. Mary's Road, Reigate, second.

Mr. H. Prouting, gardener to H. Somers Somerset, Esq., The Priory, won the Reigate Tradesmen's cup offered for the best six vases of single varieties, six sprays per vase; Mr. Prouting was the holder in 1910 and 1911, but was displaced by Mr. Hunt in 1912. This year Mr. Hunt had to be content with second place. Mr. Prouting had excellent flowers of Mensa, Metta, Ivor Grant, Sandown Radiance, Sussex Yellow, and Crown Jewel Improved; Mr. W. A. Dobson third; six entries.

In a small growers' class for six vases of single varieties, a Tradesmen's Challenge Cup was also offered as premier award, and this fell to Mr. C. Washington, gardener to C. Daniel, Esq., The White House, for Countess of Egmont, J. B. Lowe, Chas. Kingsley, Ideality, Crown Jewel Improved, and Edith Mileram, all well shown; Mr. A. C. Walton, gardener to A. G. Ashby, Esq., Mead Lodge, second; and Mr. P. Sherlock, gardener to J. B. Crosfield, Esq., Undercroft, third. The latter was the winner in 1912.

Mr. Bassett led for a vase of five yellow Japanese blooms with F. S. Vallis in grand condition; Mr. Blackwood second. For a vase of white Japanese blooms, Mr. Bassett scored with lovely and large flowers of Queen Mary, in six entries; Mr. Dobson second, and Mr. Hunt, gardener to G. Jackson, Esq., Churchfield, third. In the "any other colour" class Mr. Bassett was once more first, and this time with H. E. Converse; Mr. Dilly, Batts Hill, second, with W. Mease; and Mr. Dobson third. Mr. Hunt had the finest vase of incurved blooms, and Mr. F. Phillips, gardener to Colonel Sir R. W. Inglis, Craigendowie, second.

Mr. Dobson was first for a vase of decorative varieties, ten entries; and Mr. P. Sherlock scored for a vase of singles, nine entries. For a dozen Japanese blooms, distinct, in two vases, Mr. Bassett continued his conquering way, with Mr. Phillips second

and Mr. Prouting third. For two vases each of Japanese, single, and decorative varieties, Mr. Prouting was a capital first among six entries; Mr. R. Payne, Sandhills Gardens, Betchworth, second; and Mr. J. Dilly third.

In a special class for a big vase of chrysanthemums, quality and effect to be considered, Mr. Phillips scored with a superb vase of huge blooms of F. S. Vallis, Mrs. Drabble, etc., grandly arranged; Mr. J. T. Mitchell second, and Mr. Dobson third, the latter showing singles famously.

GROUPS AND PLANTS.

Single chrysanthemums in groups are a fine feature at Reigate, and the fine exhibits along one side of the large hall proved a great attraction. An improvement in staging is needed on the part of some competitors, or, rather, we should say that in some cases a number of dwarfer plants should be grown so that the group may be well and pleasingly finished. However, we do not wish to be severely critical. Mr. F. Kemp, gardener to E. V. Nicholl, Esq., Oakwood, Redstone Hill, won first prize with fine plants carrying excellent flowers, and the whole well arranged with due regard to colour blending and elegance; Mr. J. Giles, gardener to Miss Trollope, Eastnor Cottage, second, with a fine exhibit, in which there was a trifle of formality, and an endeavour, which the single flower would not quite permit, to secure that uniformity of outline so common in the old days, when every group of big blooms sloped with the regularity of a roof. Mr. J. A. Steadman, gardener to Dr. E. C. Prince, The Shrubbery, third; and Mr. J. G. Walder, gardener to Paul von Fleischl, Esq., Shagbrook, fourth.

Mr. W. A. Dobson, gardener to A. J. Waby, Esq., Stone House, was the only exhibitor of a table group of big Japanese blooms set amid suitable foliage plants; he now secures the challenge cup. He used crotons, small pteris, and variegated drooping ficus for foliage plants, and had splendid flowers of Mrs. Drabble and other good sorts rising from them.

In the pot plant class Mr. Prouting scored for a specimen single chrysanthemum, and Mr. J. Giles for a specimen decorative variety; Mr. H. Coleman, gardener to F. Budgen, Esq., Highfield, led for six primulas, and Mr. Blackwood for six cyclamens; while Mr. Scutt was awarded first prize for six zonal pelargoniums, freely flowered.

There were five entries of six plants of Begonia Gloire de Lorraine, and here Mr. W. Scott, gardener to H. L. Shelton, Esq., Lowwood, was a good first with large, fresh, freely-flowered specimens; Mr. W. M. Blackwood, gardener to J. Auerbach, Esq., Hethersett, came second; and Mr. Dobson third. There was not nearly enough room to show these begonias off to the best advantage.

FLORAL DECORATION.

A pretty arrangement of yellow chrysanthemums, selaginella sprays, and asparagus fronds, secured for Mrs. A. C. Brown, Brokes Lodge, Reigate, the premier place for table decoration; the combination of large and small blooms was capital, the base of the centrepiece being filled in with incurved blooms and a few small singles, while pompons and thread-petalled flowers were used above and in the corner vases; Mrs. Walter Morrison, Theydon, Reigate, second, with crimson, yellow-centred single flowers, which would have looked far better had more suitable foliage than maidenhair fronds been used with them. Miss H. Brown, Brokes Lodge, Reigate, scored for a large vase of decorative chrysanthemums, with white and yellow flowers of good size, associated with prunus and spiræa sprays; Miss Shelton, Lowwood, second, with a capital arrangement, somewhat depreciated by the lack of a couple of blooms in the centre. There were five large vases of single blooms and suitable foliage, and here Mrs. A. C. Brown came first with a very elegant and pleasing vase of large, bright yellow, soft bronzy yellow, and crimson flowers, and suitable autumn-tinted foliage; the same lady secured the piece of plate for the best exhibit in this and the latter class with this vase of singles; Miss M. C. West, Firthdene, Reigate, second, with a design that was a trifle formal, and needed a few shorter-stemmed flowers to give the centre a more finished appearance. We liked the vase put up by Miss H. Brown in the class of white and rosy-pink flowers, but noticed that the side away from the spectator lacked the grace of the front—no doubt an improvement in this respect would have secured a prize.

FRUIT AND VEGETABLES.

Mr. Bassett scored for half a dozen dishes of apples in a good class, and Mr. Dobson had the best pair of dishes—Benheim Orange and Cox's Orange Pippin. Mr. Sargent had the best two bunches of grapes—Alicante; Mr. Walden second. In the vegetable classes, which were few, Mr. Sargent, Mr. Phillips, Mr. Dilly, Mr. Peters, gardener to W. D. Jupe, Esq., Wynscot, and Mr. Mottrell, gardener to R. B. Lemon, Esq., Wragmill, were the leading prizewinners.

Congress of the French Chrysanthemum Society.

The eighteenth annual congress of this society was held in Ghent, in conjunction with the Floralies de l'Automne on the 25th to 28th ult. Quite a large number of members attended, and the numerous festivities in which they took part were much appreciated. The serious part of the business began on Monday, the 27th ult., in a large hall in the Grand Palais des Fêtes. Here, under the presidency of M. Viger, who was supported on the platform by Messrs. Vernieuwe (representing the Belgian Minister of Agriculture), Firmin de Smet, Couillard, Rosain-Boucharlat Dubreuil, Rible, Toscanelli, Quentin (President of the Conseil Général de la Seine), Callier (President of the Ghent Society), Ph. Rivoire (secretary of the French N.C.S.), and Harman Payne, the proceedings began.

The first paper was on "Insect Pests and Diseases of the Chrysanthemum," by Dr. J. Chifflot, of Lyons. This was followed by another, contributed by M. Godde, chiefly on chemical subjects. M. Couillard dealt with a proposal for a revision of the classification. There was a good deal of discussion arising out of each subject. Among the speakers were the Chairman, M. Crepin, M. Clement, Mm. Decault, Couillard, Payne, etc. The Congress Medal was awarded to Dr. Chifflot, and another to M. Firmin de Smet. M. Godde also had a similar award. The Chairman announced that the French Government had decided to promote M. Couillard to the rank of Officer of the Mérite Agricole.

Before concluding, the Belgian Secretary of the International Congress distributed invitations to the members to attend the formal closing of the exhibition by the King of the Belgians, and the distribution of prizes, which took place in the presence of many thousands of visitors in the vast hall known as the Grand Palais des Fêtes.

The Royal Agricultural and Botanical Society of Ghent entertained the Congress members at a reception given in the ball room of the Casino on Sunday evening. On Tuesday there was an excursion to Bruges, where, under the guidance of the Curator of the Museum, visits were paid to all the objects of interest in the town. The afternoon was spent at Messrs. Sanders' nursery. On this occasion M. Firmin de Smet gave a lunch to the whole party at the Hôtel de Londres. He was thanked in the name of the French members by M. Couillard, and on behalf of the English ones by Mr. Harman Payne, in one of his characteristic French speeches that was most enthusiastically received.

The members were provided with free tickets for the International Exhibition, and enjoyed other advantages, which were much appreciated.

Derby.

NOVEMBER 7 AND 8.

The annual chrysanthemum show of the Derbyshire Gardeners' Association was held at the Albert Hall, Derby, and, in the unavoidable absence of the President, Mr. H. M. Gray, J.P., C.C., Broompark, the opening ceremony was presided over by Alderman C. Boam, J.P., who was supported by other patrons of the society. Sir Thomas Roe, M.P., in declaring the show open, congratulated the promoters, and endorsed the opinion that the show certainly surpassed any previous effort.

All available space was utilised, and the whole presented a mass of floral wealth. Among the non-competitive exhibits was an imposing display of miscellaneous plants from the Rev. Henry Buckston, Sutton Hall (gardener, Mr. A. Shambrook), and which was awarded a gold medal; the group filled a space of 150 square feet, and consisted chiefly of Begonia Gloire de Loraine and B. Turnford Hall, Cyclamen Mrs. Buckston, and some new hybrids, with Cattleya Bowringiana violacea Vanda cærulea, and Begonia Ideala in the centre, with ferns, etc., around. A fine specimen single yellow chrysanthemum came from Mr. A. Preston Jones, Mickleover House (gardener, Mr. J. Bacon) and bore 320 blooms; this was sufficient to merit special comment. Mr. Jones has, as an incentive, kindly offered the Derby society two silver cups for 1914—a gift much appreciated.

Miss Wilmot, Chaddesdon Hall (gardener, Mr. J. Evans) sent a number of well-grown Japanese blooms. Mr. J. H. Goodacre, V.M.H., gardener to the Earl of Harrington, Elvaston Castle, staged a superb exhibit of fruit in his usual grand style, which was another feature of the show (silver medal).

The cut bloom portion was unusually well represented, and flowers of remarkable size came from Sir W. A. H. Bass, Bart., Byrkley (gardener, Mr. R. Nisbet); Mr. Oswald Mosley, Rolleston Hall (gardener, Mr. H. Collier); and Mr. C. W. Catt, The Outwoods (gardener, Mr. J. H. Coley). Mr. Mosley's Lady Talbot was the premier bloom. Sir W. A. H. Bass secured first honours for six vases of Japanese, and the most striking variety was R. Luxford; Mr. C. W. Catt closely followed, and Mr. F. Meakin was third. For eighteen Japanese on boards, Mr. Oswald Mosley led with Lady Talbot, Valerie Greenham, H. E. Converse, Hon. Mrs. Lopes, Frances Joliffe, F. S. Vallis, R. Luxford, Mrs. G. Drabble, Mrs. G. C. Kelly, Mrs. C. H. Totley, Rose Pockett, Geo. Hemmings, Miss A. Nicol, Walter Jinks, Marquis of Northampton, Mrs. Marsham, W. A. Etherington, and Edith Smith. For twelve incurved Mr. Mosley was in front of Sir W. A. H. Bass and Mr. J. Wood, Alvaston.

For a group of chrysanthemums, 6ft. by 5ft., Mr. A. Preston Jones was clearly ahead of Mr. Buck, and of Mr. G. Potter, Derby. The winners in a second group class were Mr. A. Cripps, Mr. S. Potter, and Mr. J. White, Derby.

In the various classes for single varieties in vases there were numerous entries, and the exhibits elicited admiration. There was also a large entry in the class for an epergne or basket; the successful contestants were Sir W. A. H. Bass, Mr. C. G. Durham, Whatstandwell, and A. Cripps.

For twelve pots of cyclamens there were only two entrants. Mr. G. H. Strutt, Makeney House (gardener, Mr. G. T. Pallett), was declared first, and Mr. C. W. Catt second.

The remaining classes were fully represented, and the exhibits in the artizan classes were an advance on previous years.

There were twelve collections of vegetables, and the chief winners were Mr. O. Mosley, Mr. H. C. Smith, Alvaston, and Mr. J. White, while for fruit Captain Drury-Lowe, Locks Park, exhibited the best grapes, and fine apples were noticed from Rolleston Hall.

Edinburgh Chrysanthemum Show.

The Scottish Horticultural Association held its 28th annual Chrysanthemum Exhibition in the Waverley Market, Edinburgh, on the 13th, 14th, and 15th inst. There was a slight increase in the entries over those of 1912, and the show was one of great excellence. Favoured by good weather, the attendance of the public was very satisfactory, and the takings at the gates were about £130 above those of last year. A bazaar in aid of the Horticultural Institution Fund was held along with the show, and this realised over £800. The Hon. Mrs. Stirling, of Keir, opened the show and bazaar.

CUT FLOWERS.

A change was made this year in the premier class for cut blooms, for which the City of Edinburgh Queen Victoria Memorial prizes were offered. Formerly this consisted of fifteen vases of cut blooms, in fifteen varieties, three blooms in each vase, but it was decided this year that the prizes should be offered for a display of chrysanthemums, arranged on a table ten feet by eight feet, with ferns, foliage plants, or cut foliage, or any combination of these, and to be seen from all sides. There were five entries, and the first prize—the City of Edinburgh Cup (to be won three times) and £12—was awarded to Mr. D. Kidd, gardener to the Right Hon. Lord Elphinstone, Carberry Tower, Musselburgh. Mr. Geo. Scott, gardener to A. Sinclair Henderson, Esq., Seathwood, Dundee, won the second prize of £8; Mr. G. Little, gardener to the Hon. Mrs. Askew Robertson, Ladykirk, Norham-on-Tweed, was third; and Mr. Jas. Fraser, gardener to Mrs. Simson, Bonaly Tower, Colinton, was fourth.

The Scottish Challenge Cup class, which was formerly confined to gardeners and amateurs, was now made an open one, the number of vases being increased from eight to ten, and as many varieties, and the prize money increased, so that it became the leading class for large blooms. The first prize—the cup and £8—was won by Mr. R. Stewart, gardener to Sir James Sivewright, Tulliallan Castle, Kincardine-on-Forth; the second (£6) by Mr. James Small, gardener to J. Graeme Thomson, Esq., Norwood, Alloa; the third (£4) by Mr. R. Mackenzie, gardener to J. T. B. Baillie, Esq., Dochfour, Inverness; and the fourth (£2) by Mr. D. McLean, gardener to the Right Hon. R. C. Munro Ferguson, M.P., Raith, Kirkcaldy. Mr. Stewart's varieties and the points awarded to them were as follows:

Variety Shown.	Maximum Points.	Points Awarded.
Fred Green	12 ...	10½
D. B. Crane	12 ...	9½
Queenie Chandler ...	12 ...	9½
Eclipse	12 ...	9½
Edith Jameson	12 ...	9½
Lady Conyers	12 ...	9
Fred Chandler	12 ...	11
Wm. Turner	12 ...	11
Francis Jolliffe	12 ...	10
Reginald Vallis	12 ...	9½
	120	99

Mr. Small had 89½ points; Mr. Mackenzie, 84½ points; and Mr. McLean 78½ points, out of 120.

In the class for six vases of Japanese chrysanthemums, six varieties, three blooms in each vase, Mr. H. MacSkimming, gardener to W. T. McLellan, Esq., Auchenault, Helensburgh, was awarded first prize; Mr. J. Waldie, gardener to W. H. Dobie, Esq., Dolarranged for effect; Mr. Jas. Bruce, Davidsons Mains, was first for six varieties of singles, not more than eighteen disbudded blooms in each vase, and all flowers facing one way (for which Messrs. Wells and Co. offered a silver cup and medals); Mr. W. Aitchison, gardener to Mrs. Hunter, of Thurston, East Lothian, was first for three vases of singles, not more than twelve sprays in each vase; and Mr. Wm. Galloway was first for three vases of singles, not more than twelve sprays in each vase, for quality and decorative effect.

Mr. James Bruce was placed first for six vases of chrysanthemums as grown for market, in six varieties, and not more than eighteen sprays or eighteen disbudded blooms of singles, and not more than twelve sprays or twelve disbudded blooms of doubles in each vase; Messrs. Todd and Co., Musselburgh, were second.

The silver medal offered by the association for the best new chrysanthemum was secured by Messrs. W. Wells and Co., Merstham, Surrey, with Mrs. Tresham Gilbey; and Mr. A. S. Watt, Whiting Bay, Arran, was awarded the bronze medal for Mrs. A. S. Watt.

EDINBURGH CHRYSANTHEMUM SHOW: FIRST PRIZE DISPLAY OF BLOOMS AND FOLIAGE,
Arranged by Mr. D. Kidd, Carberry Tower, Musselburgh.

larbeg, Dollar, was second; and Mr. J. Moir, gardener to James Mann, Esq., Castlecraig, Dolphinton, was third.

For twelve blooms of Japanese chrysanthemums, in twelve varieties, shown on boards, Mr. Alex. S. Watt, Whiting Bay, Arran, was placed first, Mr. Jas. Small second, and Mr. H. MacSkimming third.

Mr. R. Stewart, Tulliallan, was placed first for two vases of Japanese chrysanthemums, one variety, three blooms in each vase; Mr. Jas. Small for four vases Japanese chrysanthemums, in twelve varieties, three blooms in each vase; and Mr. David Bowie, Kincardine-on-Forth, for four vases Japanese chrysanthemums, four varieties, three blooms in each vase, and two vases Japanese chrysanthemums, six varieties, three blooms in each vase. The silver medal for the best bloom in the show was awarded to Mr. G. Little, Ladykirk, for a very fine flower of Purity.

In the decorative classes, Mr. Wm. Galloway, gardener to the Earl of Wemyss, Gosford, Longniddry, took first place for three vases, in three varieties, not more than a dozen sprays in a vase, for quality and decorative effect; Mr. R. Whannell, gardener to Colonel More Nisbet, The Drum, Midlothian, led for a vase of disbudded flowers, Mr. Jas. Wilson, gardener to Sir John Gilmour, Bart., of Montrane, Leven, won the first prize (Messrs. Young and Co.'s challenge cup, to be won three times in succession, or four times in all, and £1), for one vase of perpetual carnations, in at least six varieties; and Mr. Wm. Hart, gardener to P. Anderson, Esq., the Manor House, Dunbar, was placed first for a vase of twelve perpetual carnations.

BOUQUETS AND FLORAL DESIGNS.

Mr. James Beats, gardener to Mrs. Boase, Binrock, Dundee, took first honours for a bride's and two bridesmaids' bouquets, for a bouquet of flowers other than chrysanthemums, for a hand bouquet of chrysanthemums, a basket of hardy foliage and berries arranged for effect, and a floral wreath. Mr. A. Knight, gardener to Sir Wilfrid Lawson, Brayton, Carlisle, was first for a bouquet of chrysanthemums; Mr. Geo. Scott, Seathwood, for a basket of chrysanthemums, and three best-arranged sprays of chrysanthemums for ladies' wear; Mr. D. Halliday, gardener to W. Mackay, Esq., Ascog, Bute, for a basket of flowers, exclusive of chrysanthemums, and for a basket of orchid blooms arranged for effect; and Mr. H. MacSkimming

PERPETUAL-FLOWERING CARNATION SOCIETY.

THE 15th EXHIBITION
will be held at
THE ROYAL HORTICULTURAL HALL,
WESTMINSTER,
on WEDNESDAY, December 3rd, 1913.
Open 12 noon to 5 p.m. Admission 1s.
Schedules and other particulars from the Hon. Secretary,
T. A. WESTON, Floradale, Orpington.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

for a hand bouquet of flowers other than chrysanthemums.

Mr. D. Kidd, Carbery Tower; Mr. Geo. Scott, and Mr. J. Beats were placed first, second, and third respectively for the floral decoration for a dinner table, 10ft. by 5ft. (orchids excluded).

In the classes for ladies, Mrs. MacLachlan, Gracemount, Liberton, was placed first for the best arranged epergne of chrysanthemums, and Mrs. J. Donaldson, Kirn, for the best arranged vase of chrysanthemums.

PLANTS.

Mr. W. Michie, gardener to Jas. Chisholm, Esq., Edinburgh, took first place in the classes for six chrysanthemums (singles and pompones excluded); four Japanese chrysanthemums, and a single chrysanthemum; and Mr. Thos. D. Hodge, gardener to George Cowan, Esq., Edinburgh, was placed first for two chrysanthemums, one large-flowered chrysanthemum, and six chrysanthemums in 7in. pots.

In the other plant classes, the chief prizewinners were Mr. J. Templeton, gardener to Mrs. Rose, Richmond House, Glasgow; Mr. A. McMillan, gardener to the Earl of Home, Douglas Castle, Lanark; Mr. A. A. Law, gardener to Wm. Baird, Esq., Elie House, Fife; Mr. Geo. Anderson, gardener to the Right Hon. A. J. Balfour, M.P., Whittingehame; Mr. D. McLean, Raith; Mr. W. Robertson, gardener to Miss Balfour-Melville, Pilrig House, Edinburgh; Mr. A. Williams, gardener to the Right Hon. Lord Strathcden and Campbell, Hartrigge, Jedburgh; Mr. R. Whannell; Mr. J. McNeill, gardener to Major Thorburn, Craigerne, Peebles; and Mr. P. McMarrie, gardener to W. H. Coats, Esq., Woodside, Paisley.

FRUIT.

For the collection of eight dishes, distinct, the entrants were Mr. Wm. Galloway, Gosford; Mr. D. Kidd, Carbery Tower; and Mr. D. Halliday, Ascog, Rothesay, and the prizes were awarded to them in the order given.

In the grape classes, Mr. G. Halliday took first place for four bunches, distinct, for two bunches, for two bunches of Alicante, and for a bunch of Appley Towers. Mr. Wm. Galloway was first for two bunches of Muscat of Alexandria; Mr. J. Waldie, Lollarbeg, for two bunches of Gros Colmar; Mr. G. Chaplin, gardener to T. A. Nelson, Esq., Edinburgh, for two bunches of Lady Downes; and Mr. W. G. Pirie, gardener to C. W. Cowan, Esq., Dalhousie Castle, Midlothian, for a bunch of Lady Hutt.

Mr. J. Duff, gardener to Colonel Gordon, Threane House, Castle Douglas, was first for eighteen dishes of apples, not less than twelve varieties, grown in Scotland; and Mr. J. Whittle, gardener to Lieut.-Colonel Borton, Cheveney, Hunton, Kent, was first for eighteen varieties of apples, in an open class. Mr. Chas. Webster, Gordon Castle; and Mr. R. Currie, gardener to the Rev. G. H. Davenport, Foxley Hall, Hereford, won prizes for pears.

Mr. R. G. Sinclair, Congalton, East Lothian, took first place for three baskets of dessert apples, as grown for market; and Mr. John Mackenzie, Lochend, Dunbar, was placed first for three baskets of culinary apples, as grown for market.

VEGETABLES.

For a collection of nine distinct kinds of vegetables, selected from the list in the prize schedule, Mr. R. Stuart, gardener to Viscount Maitland, Thirlestane Castle, Lauder, was first; Mr. W. P. Bell, gardener to the Earl of Home, Bothwell Castle, second; and Mr. Wm. Harper, gardener to A. Ackland Allan, Esq., Tulliebelton, Perthshire, third.

In the single dish classes, the chief prizewinners were: Mr. A. McMillan, Mr. A. A. Law, Mr. R. Mason, Lanark; Mr. P. McLaren, Ballencrieff; Mr. W. Galloway; Mr. S. Murray, gardener to Sir Duncan E. Hay, Bart., Kerfield, Peebles; Mr. J. W. Scarlett, Inveresk; Mr. Charles Shaw, gardener to Stephen Mitchell, Esq., Boquhan, Kippen; Mr. Jas. Borrowman, gardener to Lady Sinclair, Stevenson House, Haddington; Mr. R. Staward, Hertford; Mr. Charles Davidson, Pencaitland; Mr. J. Waldie, Dollarbeg; Mr. J. Cossar, gardener to Miss Watt, Spott, Dunbar; Mr. S. Gordon, gardener to Sir Herbert Maxwell, Bart., Monreith, Wigtownshire; and Mr. W. Craig, Duns.

In the classes for market garden produce, confined to Edinburgh market growers, Mr. G. M. Service, Gilmerton, was placed first for leeks, and for a collection of vegetables.

NON-COMPETITIVE EXHIBITS.

Gold medals were awarded to Messrs. W. Wells and Co., Merstham, Surrey, for chrysanthemums; Messrs. Dobbie and Co., Edinburgh, for potatoes; and the Government of the Province of British Columbia for apples. Mr. D. W. Thomson, Edinburgh, was awarded a silvergilt medal for conifers, and also for winter-flowering begonias; and Messrs Storrie and Storrie, Glencarse, received a similar award for fruit trees. Silver medals were awarded to Messrs. Dobbie and Co., for chrysanthemums; Messrs. W. Cutbush and Son, London, for carnations; and Mr. D. McLeod, Chorlton-cum-Hardy, for cypripediums. Messrs. Young and Co., Cheltenham, and Messrs. John Forbes (Hawick), Lim., received bronze medals for carnations, and carnations and other flowers respectively.

AWARDS.

First Class Certificate.—To Carnation Champion, from Messrs. Wells and Co.

Certificate of Merit.—To Carnation Peerless, from Messrs. Wells and Co.; and to incurved Japanese chrysanthemum, Mrs. Ker, from Messrs. J. Ker and Sons, Lim., Penrith.

Hull Chrysanthemum Show.

The annual exhibition of the Hull Chrysanthemum Society opened on Wednesday, November 19, and was a brilliant success. The City Hall was crowded with plants, flowers, fruits, and vegetables, and the quality was high throughout. The groups formed a glorious feature. Mr. T. Petch, Bridlington, and Mr. H. Walmesley were first and second respectively. Mr. A. Chandler, Rugby, and Mr. Fleming, Grimsby, were first and second in order for twenty-four Japanese blooms; for eighteen, Mr. G. Burrows, Grimsby, and Mr. J. Backhouse, Beverley, were the chief prize-takers. Mr. Wilson, Burton Hall, and Mr. G. Musk obtained the principal award for eighteen incurved blooms. We shall give a full report in our next issue.

East Anglian Horticultural Club.

There was a very large gathering of members at the November meeting, to hear a lecture by Mr. Edward Peake upon "Leaves and Flowers." Mr. Peake is thoroughly versed in matters botanical, and by means of a lantern and a fine selection of slides made his subject of great interest. The members listened with every attention, and were sorry when the lecture ended.

There was a good collection of exhibits of flowers, fruits, and vegetables, special mention being due to Mr. W. Shoesmith for his apples and his fine lælia, and to Mr. W. Marjoram, gardener to W. T. Jarrold, Esq., Thorpe, for his superb bunch of Alicante grapes.

Winchester.

NOVEMBER 12 and 13.

The annual autumn display was held in the Guildhall, and was a distinct success. In the principal classes the competition was keen, and the exhibits of superior quality. The hall itself is an admirable place, being light and of a warm tone of colour that harmonises so well with a floral display. As usual the arrangements were excellent, Mr. Saunders, secretary, having the valued and experienced aid of Mr. Oxford in arranging the exhibits.

PLANTS.

For a group of plants arranged in a space 8 feet by 7 feet there were four entries. The premier award was made in favour of Mr. W. Paice, gardener to the Lady Brandreth, Heathfield, Winchester, who had superior blooms on dwarf plants, all neatly edged with single-flowered varieties and ferns; Mr. W. Pearce, gardener to H. E. Johnson, Esq., Northgate Place, Winchester, second; and Mr. J. Edsall, gardener to Major C. P. Holroyd, Ropley House, third. The class for nine plants, in not less than six varieties (each plant to carry not fewer than five blooms), in pots not more than 9½ inches across, generally provokes keen competition here. This time there were but two entrants, and Mr. G. Cousins, gardener to J. A. Fort, Esq., The College, Winchester, led with plants carrying excellent blooms and good foliage—the varieties Frances Joliffe, F. S. Vallis, W. Mease, and Mrs. Gilbert Drabble were the best. Mr. H. Gigg, gardener to Mrs. Moorsom, Holyrood, Winchester, a good second. For nine plants, any white and yellow varieties, under similar conditions to the former class, Mr. G. Cousins was again the chief prizewinner with plants fine in every respect, and F. S. Vallis was especially noteworthy; Mr. Gigg was again second.

In a class for six plants suitable for conservatory decoration, with not less than eight blooms on each, Mr. T. W. Stone, gardener to the Rev. A. G. Bather, Sunnyside, Winchester, was first with excellent examples, among which Splendour was especially fine; Mr. J. Smith, gardener to H. Aris, Esq., 69, Kingsgate Street, Winchester, second. Single-flowered varieties were well represented, and Mr. Cousins was first for six plants, distinct, and Mrs. W. Buckingham was quite the best variety in a good collection; Mr. F. W. Stone second. Mr. Cousins had the best single specimen—W. Mease—carrying eight handsome blooms; Mr. W. Stone followed with F. S. Vallis in fair condition.

Miscellaneous plants arranged for effect were but moderately displayed, and Mr. James Hayes, gardener to Captain H. Bull, St. Phillip's, Winchester, was first prizewinner.

CUT BLOOMS.

The leading class in this section was for eighteen Japanese blooms and the same number of incurved, in not less than twenty-four varieties. Unfortunately there were but two entries. Mr. Cyrus Moore, Frensham Place, Farnham, won the premier award with full-sized Japanese blooms nicely set up, and fairly good incurved blooms. The most noteworthy varieties were Frances Joliffe, W. Turner, Frances Rowe, Alice Lemon, Mrs. G. Drabble, F. S. Vallis, Miss J. Stratton, Bob Pulling, Master James, and T. Lunt among Japanese, and G. W. Matthews, Topaze Orientale, Embleme Poitivine, Marjorie Shield, Mrs. G. Denyer, Ialine, W. Biddle, and Romance among incurved. Mr. D. Edwards, gardener to W. Garton, Esq., Sarisbury Court, Southampton, second, with smaller examples of Rose Pockett, Hon. Mrs. Lopes, Mrs. Kelly, Romance, and Clara Wells. Five entered the class for twelve Japanese, distinct, and Mr. J. Goatley, gardener to Lord Northcliffe, Sutton Place, Guildford, was easily first with huge specimens of His Majesty, H. E. Converse, F. S. Vallis, Joan Stratton, Mrs. G. Drabble, and Mrs. H. Stevens; Mr. W. H. Cole, gardener

to Mortimer Gale, Esq., Warley, Twyford, second, with a creditable set.

Only three entered for six Japanese, distinct, arranged in vases, and Mr. Goatley, with Queen Mary, Thos. Lunt, Fred Green, Mrs. G. Drabble, F. S. Vallis, and H. E. Converse, was first, with Mr. C. Moore a good second. Mr. Edwards had the best of four exhibits for twelve incurved, with well finished, medium-sized blooms of Edwin Thorpe, Romance, and W. Pascoe; Mr. Moore followed.

Two new classes were arranged, and produced a large entry; but unfortunately the space provided for them did not allow the exhibits to be shown to the best advantage. The first was for a vase of Japanese varieties, arranged for effect with any foliage, and here there were nine entries. Mr. J. Goatley, with bronze and yellow blossoms most harmoniously arranged with yellow beech foliage, secured the leading award, and Mr. R. Learmouth, gardener to John Liddell, Esq., Sherfield Manor, Basingstoke, was second, with F. S. Vallis and red autumn foliage. No fewer than twelve competed in the class for a vase of undisbudded varieties arranged for effect with any foliage. Mr. L. Carsley, gardener to the Countess of Northbrook, Stratton Park, Micheldever, was distinctly first with mixed single varieties effectively blended with autumn foliage, in which sprays of berberis were most telling; Mr. P. Learmouth was placed second with Edith Pagram and red acer sprays, which proved a crude colour scheme.

Single-flowered varieties were freely contributed, and for six bunches, distinct, not disbudded, nine entered. The best, a charming display, came from Mr. G. Ellwood, gardener to W. H. Myers, Esq., Swanmore House, Bishop's Waltham, and he was closely followed by Mr. Carsley. For six bunches, any section except singles, and not disbudded, Mr. C. Smith, gardener to A. H. Evans, Esq., Horris Hill, Newbury, was first, with Mr. W. Hunt, gardener to Lord Ashburton, The Grange, Alresford, an exceedingly close second.

FRUITS AND VEGETABLES.

Fruit was plentifully staged. Mr. Ellwood secured the leading award for two bunches of black grapes with Mrs. Pince. Mr. T. Hall, gardener to Ellen Lady Swaythling, South Stoneham House, Southampton, won for two bunches of any white grape with Muscat of Alexandria. For four varieties of dessert apples there were eight entries, and Mr. A. Basile, gardener to the Rev. McMurdie, Woburn Park, Weybridge, was easily first with good specimens of popular varieties. Mr. Basile, in an even stronger competition, won with four dishes of kitchen sorts, and also led for four dishes of pears with large, clean fruit.

Mr. Ellwood easily annexed the premier awards in the vegetable classes provided by Messrs. Toogood and Sons and Messrs. Sutton and Sons, for six varieties.

LADIES' CLASSES.

For the most tasteful table decoration of chrysanthemums, with foliage and grasses, there were five entrants. Mrs. Bealing, Bassett, Southampton, was first with an effective arrangement of bronze flowers; Mrs. A. Saunders, Western Road, Winchester, second. Miss Margaret Fort, The College, Winchester, had the most tastefully arranged stand of single chrysanthemums suitable for table decoration, and Mrs. A. Smith, 17B, Front Street, St. Cross, Winchester, secured the leading award for a stand of flowering shrubs, foliage, grasses, etc.; Mrs. A. Saunders second.

NON-COMPETITIVE.

Mr. W. H. Myers sent three dozen dishes of apples of excellent quality. Messrs. E. Hillier and Sons, Winchester, arranged apples and carnations effectively. Mr. E. J. Wootten, Fair Oak, had carnations in quantity. Messrs. Sutton and Sons, Reading, filled the front of the stage with a magnificent bank of vegetables, all of the highest quality.

EDINBURGH CHRYSANTHEMUM SHOW: LARGE BLOOMS IN THE SCOTTISH CUP CLASS.
The first prizewinner was Mr. D. Stewart, Tulliallan Castle, Kincardine.

Tunbridge Wells.

The chrysanthemum show in connection with the Tunbridge Wells Gardeners' Mutual Improvement Association was held recently in the Great Hall, when, as in the past, the exhibitors fully maintained their high standard of efficiency. The arrangements were in the capable hands of Mr. E. Charlton, chairman, Mr. H. Hollingsbee, secretary, and a strong committee.

In the class for a group of chrysanthemums in pots, arranged in a space 8ft. by 6ft., Mr. A. G. Corner, gardener to Mrs. Beer, Chancellor House, Tunbridge Wells, secured the first prize and challenge cup, presented by Mr. J. S. Swork, with dwarf plants in small pots, carrying fine flowers; Mr. J. Cradduck, gardener to the donor of the cup, was second, with similarly grown plants, but was not quite up to his usual form. Last year he won outright the cup presented by Mr. A. P. Hedges in the same class.

For a group of miscellaneous plants, arranged for effect, 8ft. by 6ft., Mr. Corner was again winner of the first prize and cup, presented by Mr. E. R. Ashton, with a neat arrangement, consisting chiefly of well-grown ferns, pink Lorraine begonias, nicely coloured crotons, etc.; Mr. H. Smith, gardener to F. T. A. Bomert, Esq., Broadwater Down, Tunbridge Wells, second.

CUT FLOWERS.

For eight vases of Japanese blooms, three in a vase, distinct varieties, the invincible amateur, Mr. C. Fox, of Linden Park, Tunbridge Wells, was well to the front, thus making the challenge cup, presented by Captain Spender Clay, M.P., his own property. The flowers in this exhibit were much the finest in the show, and the varieties were Mrs. G. C. Kelly, W. Turner, Mrs. G. Drabble, Mrs. R. H. B. Marsham, Master James, President Viger, Mrs. A. T. Miller, and Rose Pockett; the whole gained 51 points. Mr. Bristowe, gardener to Mrs. Temple, Leyswood, second, with 33 points.

For four vases of singles, distinct, Mr. J. Cradduck led, but, unfortunately, his varieties were unamed; Mr. Frost, gardener to Mrs. Trevenen Holland, Mount Ephraim, Tunbridge Wells, second. For a dozen incurved blooms, Mr. J. Cradduck led, with Mr. A. Wilson, gardener to the Marquis of Abergavenny, second. Mr. Bristowe was an easy first, with Mr. A. Wilson second, for eight vases of Japanese blooms; while for a dozen Japanese, distinct, Mr. A. Wilson scored with good flowers of Mrs. C. Penford, Mrs. G. Drabble, John Lock, etc.; and Mr. Bristowe was second.

For six blooms, Japanese, distinct, Mr. C. Fox was first with good flowers of Mrs. G. Drabble, D. B. Crane, W. Turner, W. Mease, Mrs. A. T. Miller, and Mrs. G. C. Kellis; Mr. Muntz, gardener to Miss E. D. Coates, Brenchley, second. In a special class for four vases of Japanese blooms, Mr. C. Fox was first, showing fine examples of Alice Lemon, H. E. Converse, W. Turner, etc.; Mr. J. Cradduck second.

In the class for a decorative vase of chrysanthemums, Mr. J. R. Allan, gardener to C. A. Morris Field, Esq., Ashurst Park, led with Mrs. A. T. Miller, used in conjunction with acer and prunus foliage, nephrolepis fronds, and trails of Asparagus decumbens.

The best group of orchids, arranged for effect in a space 5ft. by 2½ft., came from Mr.

Bristowe, who had a very pleasing arrangement, containing many choice and beautiful hybrids; Mr. A. Young, gardener to E. R. Ashton, Esq., Broadlands, Camden Park, second, with a choice collection attractively arranged.

For Begonia Gloire de Lorraine, three pots, not to exceed 6in. diameter, Mr. Corner scored with fine specimens 2½ft. through, splendidly flowered; Mr. S. Snashall, gardener to M. B. Snell, Esq., Broadwater Down, second. In a similar class, but for white begonias, Mr. Corner was again first, and Mr. Snashall second.

FRUIT.

For three bunches of black grapes, Mr. J. R. Allan led with Alicante, Mr. A. Wilson second with the same variety. For three bunches of white grapes Mr. Bristowe scored with Lady Hutt. Mr. Allan had the best six dishes of dessert pears, and had fine dishes of Marechal de la Cour, Beurre Diel, Pitmaston Duchess, Emile d'Heyst, Doyenne Boussoch, and President d'Osmonville. Mr, Allan was also first for three dishes of dessert pears, and for one dish of stewing pears with Bellisseme d'Hiver. Mr. F. French, gardener to F. Burnaby Atkins, Esq., Hamptons, Tonbridge, had the best six dishes of dessert apples, winning with good examples of King of the Pippins, Allington Pippin, Blenheim Orange, American Mother, Cox's Orange and Ribston Pippins; Mr. Bristowe second with finely coloured fruit. Mr. French was successful for three dishes of dessert apples, for six dishes of kitchen apples, and for three dishes of kitchen apples, Mr. J. R. Allan coming second in the last two classes.

Mr. J. Cradduck, and Mr. Gorham, gardener to Mrs. Gray, Broadwater Down, Mr. A. Manktelow, and Mr. A. Wilson were most successful with vegetables.

In the single-handed gardeners' classes, Messrs. Frost, Pinchin, Peele, and Dann were the chief prizewinners.

NON-COMPETITIVE.

The non-competitive exhibits were an attractive feature. Mr. John Charlton, The Pantiles, Tunbridge Wells, showed single chrysanthemums, perpetual carnations, etc. Mr. L. R. Russell, Tunbridge Wells and Richmond, exhibited a group of variegated ivies and flowering shrubs. Messrs. A. Charlton and Sons, Summervale Nurseries, Tunbridge Wells, had an exhibit consisting chiefly of pink and white Lorraine and Mrs. J. Heal begonias effectively arranged.

Messrs. J. Cheal and Sons, Crawley, put up about three dozen dishes of highly coloured apples, including their new Crawley Beauty. Mr. F. French, Hampton, Tonbridge, also exhibited, not for competition, about thirty dishes of well-grown apples and pears.

National Chrysanthemum Society.

The Executive Committee of this society held a meeting at Carr's Restaurant, Strand, on Monday last, Mr. T. Bevan occupying the chair.

An offer from Messrs. W. Wells and Co., Merstham, of £10 in cash for prizes at the society's show next year, for their novelty, Daily Mail, was accepted. It was resolved, on a suggestion received from an affiliated society, that the winner each year of the Challenge Trophy should receive a certificate recording the fact, the resolution being retrospective.

The report of the Publications Committee was received and adopted, as a result of which the N.C.S. "Transactions" will be continued next year. Its contents were briefly outlined, and will consist of a report of the Ghent Show, an article on soil sterilisation, a report of this year's conference, an audit of the last November show, and probably a paper on single chrysanthemums.

The conference to be held on December 10 next will be free to all, but it was stated that admission to the show will be sixpence to non-members of the N.C.S. Members of affiliated societies will therefore have to pay only in case of their visiting the show.

From the interim financial statement we learn that prize money to the value of £167 15s. 9d. was awarded at the November show at the Crystal Palace. In 1914 the society's exhibitions will, subject to the approval of the Crystal Palace authorities, be held on October 7 and 8, and November 4, 5, and 6. It is also intended in next year's programme that a conference and a late show be held as before.

Mr. Harman Payne reported on the British exhibits at the recent Ghent Show, and on the proceedings there of the French Chrysanthemum Society's Congress.

Eighteen names were added to the list, either as Fellows or as ordinary members.

Reading Gardeners' Association.

The fortnightly meeting of this society was held on Monday at the Abbey Hall, kindly lent by Messrs. Sutton and Sons, when Mr. F. B. Parfitt presided over a good attendance.

The lecturer for the evening was Mr. E. Feltham, of the Wargrave Hardy Plant Farm, and his subject was "Alpine Plants." Mr. Feltham's quiet and convincing manner interested the audience from the commencement of his remarks. First dealing with the haunts and habits of his favourites, which have also become the favourites of so many garden lovers, he afterwards imparted useful information as to the culture of these popular flowers, and in conclusion gave full details with regard to the construction of a rock garden, advising those present to carefully think out their plan of operations, remarking that it was easier to think thrice than to move a number of (or only one) heavy stones three times.

A good discussion followed, and Mr. Feltham was accorded a hearty vote of thanks.

The hall again presented a gay appearance. Chrysanthemums were exhibited by Mr. J. T. Tubb and Mr. H. G. Cox, vegetables by Mr. G. Tovey and Mr. H. Goodger, and grapes by Mr. H. Reeves, while Mr. F. Townsend, head gardener to the vice-president, was awarded a certificate for an excellent collection of vegetables.

Scottish Horticultural Association.

The monthly meeting of this association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on the 4th inst. Mr. King, the president, was in the chair, and there was an attendance of 115 members.

Dr. W. G. Smith, of the Edinburgh and East of Scotland College of Agriculture, delivered a lecture, with limelight views, on "The Influence of Drought on Plant Form." The large size and rapid annual growth of many tropical and aquatic plants presented, he said, a strong contrast to the dwarfed form of plants grown under drought conditions. The cactus house furnished extreme drought forms evolved in hot climates with low rainfall. The rock garden, a more familiar place for observation, contained numerous examples. Here plants from many varied types of natural habitats were grown together, and required a very varied treatment. The one feature in common was inability to withstand competition, and to escape this a rock life was adopted; but, as rocks occurred mainly in exposed places, the plants must be able to meet special conditions, of which drought was important. The modifications of plant form were illustrated from experiments on plants grown at high and low altitudes, those at high levels becoming dwarfed and otherwise modified like true alpines. The liability of many alpine plants to vary under lowland cultivation was mainly due to the new environment. All rocky places tended to promote the same types of plant form, and this was illustrated in the case of limestone vegetation. The influence of peat was to produce drought forms, notably the heaths. Sand was another habitat inducing adaptations for drought.

The exhibits were: New single chrysanthemum Lady Cayzer, exhibited by Mr. R. H. Cockburn, Gartmore, Perthshire; single chrysanthemums Miss H. M. Cowan, Ceddie White, Miss Callander, and Weston Gem, exhibited by Mr. W. G. Pirie, Dalhousie Castle, Bonnyrigg.

A Cultural Certificate was awarded to Mr. Pirie for his chrysanthemums, and to Mr. W. H. Sands, Hillsborough, Co. Down, for tuber of potato, Irish Gem, exhibited at the previous monthly meeting.

Dundee Horticultural Association.

Mr. William Christeson presided at the ordinary monthly meeting of the society, held in the Technical College, on November 7, when Mr. J. S. Chisholm, of the Edinburgh and East of Scotland College of Agriculture, gave an interesting and instructive lecture on "The Cultivation of Small Fruits." Confining his remarks chiefly to the cultivation of gooseberries and currants, Mr. Chisholm (whose portrait appears in this issue) dealt with the American gooseberry mildew and the black currant mite. Cutting off the tips of the shoots affected by the mildew was not sufficient, he said, without spraying with one ounce of sulphide of potassium to two gallons of water. For the black currant mite he recommended a dry spray of two parts sulphur and one part lime.

Mr. James Staward, St. Fort Gardens, Newport, exhibited a highly meritorious lot of cyclamen growing in 4in. and 5in. pots, Sutton's Giant White being particularly fine and well-grown.

United Horticultural Benefit and Provident Society.

The monthly committee meeting of this society was held at the Royal Horticultural Hall on Monday, November 10, Mr. Charles H. Curtis in the chair. Four new members were elected. The sick pay on the ordinary side amounted to £74 10s. 4d., and in the state section to £24 8s. 10d., and maternity claims were £9. The sum of £9 10s. 10d. was passed for payment to the nominee of a deceased member, and one member was allowed to withdraw double the amount of his interest on deposit account. Important items regarding the state section of the society were dealt with, and the committee desires to point out that gardeners may transfer from the Post Office to "The United" for insurance benefit, and that the Secretary (Mr. A. C. Hill, Alexandra Road, West Kensington Park), will be pleased to forward them a form for this purpose.

TRADE NOTES.

At the recent Ideal Homes Exhibition, held at the Olympia, Kensington, a fifty-guinea gold cup was offered for the best model of a garden design. The jurors have now made their decision, and have awarded the cup to Messrs. J. Cheal and Sons, Lim.

Mr. Alfred Dawkins, who for seventeen years has been manager of the seed and bulb department of Messrs. James Veitch and Sons, Lim., Chelsea, has commenced business as a seed and bulb merchant at 408, King's Road, Chelsea, where he will be assisted by members of his old staff. Mr. Dawkins has issued a list of choice liliums and gladioli, and will soon be distributing his first seed catalogue.

Among the many inventions which save a gardener from the troubles his forebears had to contend with unaided, the Frost Predictor must rank as one of the most useful. It is a double column thermometer, with a little cistern, for water, to be placed in association with the wet bulb of one column. If the wet bulb is kept moist, and the mercury in that column sinks below the mercury in the dry bulb column, then a frost may be safely predicted, and means can be taken to prevent untoward results. Five p.m. is given as the best time to take the reading. Messrs. Short and Mason, Walthamstow, N.E., the makers, issue a little pamphlet explaining just how and why this instrument predicts frost. It is worth getting.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of THE GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notifications of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming, or opinion, should be sent to the Editor of THE GARDENERS' MAGAZINE, 2, Adelaide Road, Brentford, Middlesex, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in THE GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

BOOK ON GARDENING.—B. M. E., Menston-in-Wharfedale: I should be obliged if you will recommend me a good all-round book on gardening. I want cultural details and description of species and varieties. It is for a friend who is a keen amateur gardener.—A book of the kind you suggest would run into many volumes, and these of large size. Nicholson's "Dictionary of Gardening" comes nearest to your ideal, but for your amateur friend we recommend the "Encyclopædia of Gardening" (post free 3s. 10d., W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London, E.C.). It is far and away the most useful book of its size, and, as everything is arranged alphabetically, one may easily find any given subject. The most useful species and varieties of plants are indicated, floral colour, etc., given, and brief cultural details appended.

CHIRONIA IXIFERA.—T. B., Hassocks: Having recently purchased a dozen small plants of Chironia ixifera, in small 60-sized pots, I should be very pleased if, through the medium of the GARDENERS' MAGAZINE, you could give me a few cultural hints concerning the species. I should like to know how to propagate it, and whether I should cut the plants back or allow them to grow naturally. I should like to grow them into good-sized plants by next August.—Chironia ixifera, or, more correctly, C. linoides, is an evergreen greenhouse shrub, not difficult to cultivate, provided very free drainage is afforded, and overpotting is avoided. These are matters of the greatest importance. Light loam and some peat and sand form a good potting compost. Propagation is effected by means of cuttings inserted in very sandy soil, under a handlight or bell-glass in a greenhouse in spring. A gentle bottom heat will facilitate rooting, but a high top temperature must not be given or the cuttings will damp and rot. The leading growths should be pinched back two or three times during the growing season. Excess of water is the cause of much trouble in the cultivation of chironias and other greenhouse-flowering shrubs, therefore great care is necessary in this connection during winter. Afford a warm greenhouse temperature, with ample ventilation.

MARGUERITE MRS. SANDER.—Mr. C. Craddock, gardener to Mrs. Tyrwhitt-Drake, Coltree Manor, Maidstone, sends us a small photograph of a large specimen of the double-flowering Marguerite Mrs. Sander, growing in a big upright vase or urn. He writes: "The cutting was taken in September, 1912, and the plant was put out in June. It is now flowering for the fourth time this year, and had even more flowers during its third display than when photographed. Would you consider this a good specimen?" — The photograph was small, and not suitable for reproduction, or we would have reproduced it. So far as we could make out, there were upwards of 200 flowers on the specimen. Perhaps some of our readers will be good enough to tell us the size of the largest plant they have seen, and the number of flowers it carried. We saw a very fine example in Guernsey last year, planted as a lawn specimen, but, though we had no opportunity of counting its blossoms, we should say it was not so large as the one Mr. Craddock writes about.

MANUFACTURE OF PERFUMES.—G. L. W., Hurst.—My employer proposes to purchase a still for the purpose of making lavender perfume and other scents, so I shall be glad if you will kindly tell me where I can obtain information respecting the distillation of fragrance from aromatic herbs.—You will find "The Book of the Scented Garden," and "The Still Room," both published by John Lane, The Bodley Head, London, useful to you in connection with the distillation of perfumes; the former contains a long and excellent list of plants with fragrant flowers or fragrant leaves.

NAMES OF PLANTS.

D. G. J., Hexham. — 1, Symphoricarpus racemosus; 2, Leycesteria formosa.

S. R., Ipswich.—1, Calanthe Veitchi; 2, Rivinia humilis; 3, Cypripedium Baron Schröder.

G. H. H., Watford.—1, Cattleya labiata; 2, Oncidium varicosum Rogersi; 3, Cypripedium Arthurianum.

N. D. T., Bedford.—1, Centropogon Lucyanus; 2, Nertera depressa; 3, Skimmia japonica; 4, Cupressus obtusa; 5, Plumbago rosea.

NAMES OF FRUITS.

P. P., Derry.—Newton Wonder.

J. G. S., Tunbridge Wells.—1, Warner's King; 2, Alfriston; 3, Court Pendu Plat.

F. C., Bideford.—Very fine specimens of Lane's Prince Albert.

W. C. J., Northampton.—1, Dumelow's Seedling; 2, New Hawthornden; 3, King of the Pippins; 4, Sturmer Pippin.

C. H. A., Hampton.—1, Emperor Alexander; 2, Waltham Abbey Seedling; 3, Claygate Pearmain; 4, Pitmaston Duchess; 5, London Pippin; 6, Dumelow's Seedling.

Dahlias destroyed on Sunday, November 9.

By Special Appointment **to His Majesty the King.**

MESSRS. JAMES VEITCH & SONS, LTD.

Royal Exotic Nursery, CHELSEA.

Beg to announce that they are still carrying on every branch of their NURSERY BUSINESS for the supply of plants, trees, shrubs, vines, and fruit trees, etc., at their Chelsea, Coombe Wood, Langley, and Feltham Nurseries.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

MONDAY, November 24:—National Chrysanthemum Society; Floral Committee at Essex Hall, Strand, W.C., at 3 p.m.

THURSDAY, November 27.—Manchester and North of England Orchid Society.

Barnsley Chrysanthemum Show; two days.

FRIDAY.—November 28.—Annual Dinner of the National Chrysanthemum Society, Royal Venetian Chamber, Holborn Restaurant, W.C., commencing at 6.45 p.m.; Sir Albert Rollit, D.C.L., LL.D., in the chair.

CATALOGUES RECEIVED.

MESSRS. H. J. JONES, LIM., RYECROFT, LEWISHAM.—A pocket-sized, sixty-four paged catalogue of special interest to those who make a feature of chrysanthemums, perennial phloxes, Michaelmas daisies, pyrethrums, sweet peas, etc.

R. WALLACE AND CO., COLCHESTER.—This firm has given us something new in catalogues in their issue devoted to irises. Upwards of 350 distinct species and varieties are listed and described, and numerous illustrations are given, while three pages are occupied by an admirable article on "Garden Irises" by Mr. W. R. Dykes, who has made the genus iris his special study.

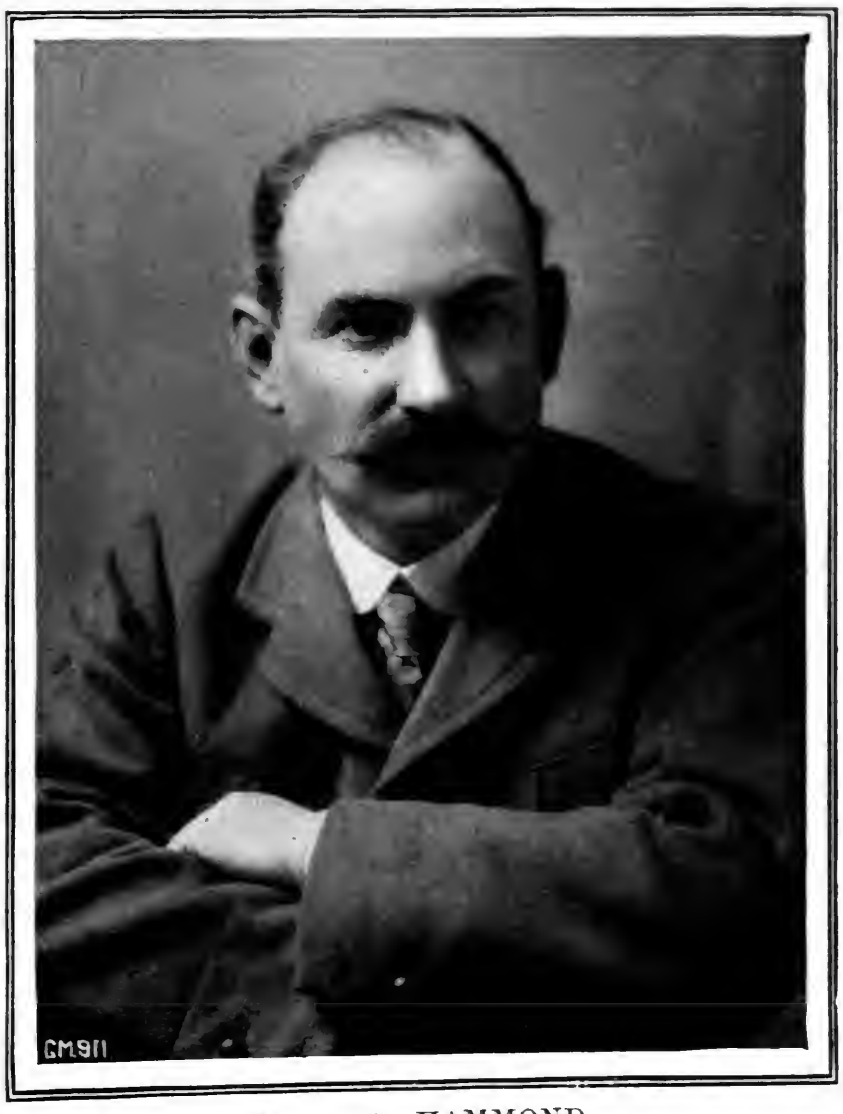
VOL. XVI.—No. 3,135. SATURDAY, NOVEMBER 29, 1913.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

New Berry-bearing Shrubs.

Although there is no good reason, as the dull days of autumn bring into prominence the brilliantly-coloured berries of the ever-popular shrub, why we should not enter heartily into the spirit of the old carol, "Heigh-ho! sing Heigh-ho! unto the green Holly," the time has come when those who are interested in the shrubbery should give careful consideration to the claims of berry-bearing shrubs of merit other than those which have had a place in British gardens for so long a time. There are not among the kinds of recent introduction any that can justify a claim for superiority to the holly, the pyracantha, and a few other of the old favourites, but many possess sufficient beauty, when laden with their brightly-coloured fruits, to entitle them to a prominent position in groups and borders. For the new, hardy, berried shrubs, as for many other hardy plants of much interest and beauty, we are indebted to the activities of Mr. E. H. Wilson, and the enterprise of those by whom his explorations in Western China were rendered possible; and among them are some of the most valuable of the newer Chinese plants. Hitherto, the estimate of the merits of these ornamental plants from Western China has been based chiefly on the habit of growth or the attractiveness of the flowers. It could not well have been otherwise, for not until they had attained some size and age was it possible to determine with necessary exactitude their berry-bearing capacity in this country. It is not enough to know that in their native homes they produce an abundance of attractively coloured fruit, and it would not be difficult to call to mind several hardy shrubs that gave great promise of usefulness in this connection, but failed to realise the promise because the climatic conditions of our land were unfavourable. Happily, many of the newer shrubs have reached the fruit-bearing stage, and the collections of Chinese plants in the Aldenham House gardens and the Coombe Wood nurseries afford ample evidence that a considerable proportion of the species and varieties bear their fruits so freely as to present a rich effect when they have attained maturity. Especially noteworthy among kinds deserving the immediate attention of planters are the berberis and cotoneasters, which include a considerable number of species that are of comparatively small growth, and therefore suitable for small gardens, for the rock garden, and for the marginal lines of broad belts of large-growing shrubs. Among the berberis of special merit are B. Coryi, a compact-growing species of upright habit, with slender growth, bearing yellow flowers on spurs and short laterals, these being followed by medium-sized fruits of the most brilliant scarlet colour. B. Wilsonæ is a dwarf-growing species of elegant habit; the flowers are bright yellow and produced so freely as to give a pleasing effect. But its chief value for decorative purposes consists in the bright coral-red fruits, which are produced in abundance; and being protected from the birds by long and sharp spines, they are retained far into the winter. B. sub-caulialatus is a stronger grower than the foregoing, is highly effective when the fruits have ripened, and, as they receive the protection of sharp-pointed spines, they contribute to the attraction of the shrubbery border for a longer period than do those to which the feathered tribe have free access. B. Geraldi is a strong-growing species of deciduous habit, and bears a profusion of deep yellow flowers, which are followed by fruits borne in dense clusters. B. Stapfiana has a dwarf habit, is elegant in growth, and bears its yellow flowers and red fruits the whole length of the slender shoots, the latter producing a rich effect during the autumn and winter. B. polyantha is a rather strong-growing species, attaining a height of five or six feet, and bearing an abundance of coral-red fruits in long racemes. B. Gagnepaini and B. verruculosa are two purple-fruited species that deserve attention for the distinct colour of their fruits, as well as for their other merits. Of the somewhat large group of new cotoneasters the following deserve special attention: Cotoneaster amœna is a charming species, dense in growth, and forms handsome specimens; the white flowers are borne in large corymbs, and present a pleasing appearance, while the brilliant scarlet fruits are so abundant as to produce a fine effect in the autumn. C. rugosa Henryi is distinct in character and elegant in growth, and the large clusters of rich crimson fruits along the slender shoots present a charming appearance. C. applanata is distinct in character, and, in point of merit, follows very closely the foregoing species. It is free in growth, profuse in flowering, and the scarlet fruits, which are produced in great abundance, remain on the plants for a long time. C. salicifolia and its varieties, glaciosa and rugosa, are free in growth and elegant in habit, the shoots being slender and pendulous, and the flowers are white, followed by brilliant red fruits. One other berry-bearing shrub must be mentioned, and that is Symphoricarpus occidentalis (mollis), an American Snowberry which is perfectly distinct from, and has much larger berries than, the common Snowberry (S. racemosus) of British gardens. It is altogether superior to that species, and should be planted wherever berry-bearing shrubs are appreciated.



Mr. G. A. HAMMOND.

Mr. G. A. Hammond, of Woodlands, Burgess Hill, Sussex, is one of the most enthusiastic amateur rosarians of the present time, and also one of the most successful. He cultivates roses extensively and skilfully in a delightful district, and he knows how to exhibit his blooms when they have been well grown. He won his first prize at a National Rose Show at the

Crystal Palace in 1897, and in 1900 he secured medals for blooms of Maman Cochet and The Bride at Reigate and Brentwood. In 1902 he won the Graham Cup, and in 1906 captured the Christy Cup. In 1908, 1911, and 1912 he won the Eltham Cup for roses, and in the latter year also won the Harkness Cup at the Royal Botanic Gardens, Regent's Park. Both in 1908 and 1909 he led at Regent's Park for nine vases of exhibition roses, and in the latter year was also successful in an extra class for two dozen blooms. Mr. Hammond is a keen competitor, and loves a close contest which brings out the skill of the grower and the exhibitor. He first served on the Council of the National Rose Society in 1904, and has rendered such considerable service to that body that in 1912 he was elected a vice-president.

"Gardeners' Magazine" Almanac for 1914.—We shall be very greatly obliged to secretaries of horticultural, floricultural, and gardeners' mutual improvement societies, if they will kindly send us dates and particulars of their meetings for 1914, so that, as far as possible, these dates may be inserted in our Almanac for the ensuing year. In most cases a postcard will hold the information we need, and it should be addressed to the Editor, THE GARDENERS' MAGAZINE, 148, 149, Aldersgate Street, E.C.

The Kew Flagstaff. — A local landmark and a conspicuous feature of the grounds at Kew is practically missing for the moment. The inspection of the great flagstaff made last summer revealed the fact that in several places it was decaying badly. For a week or more preparations have been in progress for lowering the pole to the ground, and this work was accomplished on Monday, November 24. A casual glance at the flagstaff suggests that the decay has spread so as to render repair and safe re-erection almost impossible, but this, of course, remains for experts to decide, and we understand every effort will be made to save the flagstaff, which is 159ft. high, and 20in. in diameter at the base, and a splendid example of the Douglas Fir (Pseudotsuga Douglasi), a native of British Columbia. The Kew flagstaff was presented to the Royal Gardens in 1861 by Mr. Edward Stamp, who at that time was engaged in the timber trade of British Columbia. It was taken down for repair once previously, in 1896, seventeen years ago.

New Work on Hardy Trees and Shrubs. — There is no greater authority on hardy trees and shrubs than Mr. W. J. Bean, Assistant Curator, Royal Botanic Gardens, Kew, therefore it is with great pleasure we learn that Messrs. H. Sotheran and Co. will shortly publish a two-volume book from his pen, entitled "Trees and Shrubs Hardy in the British Isles." Mr. Bean has been at work on this book for a considerable time, and we gather he has included the most recent introductions from China in his descriptive list of kinds. Cultural matters will occupy considerable space, and there will be three hundred illustrations.

Perpetual Carnations at Westminster.—The exhibition of the Perpetual-flowering Carnation Society, to be held at the Royal Horticultural Hall, Westminster, on December 3, promises to be a great success. An entirely new class for a dozen vases of blooms, twenty-five blooms in each vase, should prove an additional attraction, especially as the large growers are likely to put forth their best efforts in an endeavour to be the first to hold the splendid George Monro, jun., challenge cup, valued at 50 guineas, offered as first prize. A carnation Conference will be held during the afternoon, commencing at 3 o'clock, when Mr. G. H. Lawrence will lecture on "Carnations for Amateurs"; the Annual Meeting of the society will follow at 6 p.m.

Record of the Royal International Horticultural Exhibition of 1912.—We understand that this publication, which is rather overdue, will be issued by Messrs. J. and A. Churchill next month. Besides the descriptive and historical text contributed by well-known horticultural writers, the work will contain 117 coloured plates, and 67 half-tone illustrations, representing views or exhibits at the great gathering of 1912. Mr. Reginald Cory, of Duffryn, Cardiff, has, with commendable public spirit, made "The Horticultural Record"—as the book will be called—possible. Mr. Cory has received the gracious permission of the King to dedicate the volume to His Majesty, and we feel sure all lovers of gardens and gardening will look forward to its appearance.

Hobbies' Jubilee Dinner. — Messrs. Hobbies, Lim., Dereham, gave a dinner at the Holborn Restaurant last week, when some sixty gentlemen connected with business undertakings in Norfolk, and others interested in the welfare of the firm, were entertained on the occasion of the company's jubilee celebration. Mr. Alfred Jermyn, H.P., took the chair, the vice-chairman being Mr. Richard Jewson, of Norwich. Others present were: Dr. Hallwright, Birmingham; the Mayor of Peterborough; Mr. John Green and Mr. Herbert Jewson, of Dereham, directors; Mr. W. C. May, goods manager of the Great Eastern Railway; Mr. W. A. Vincent, of Messrs. A. W. Gamage, Lim.; Mr. F. Stephens and Mr. F. Nash, of Messrs. Horace Marshall and Son; Mr. A. H. Shaw, Editor of "The Ironmonger"; Mr. W. A. Young, Editor of the "Hardware and Ironmongers' Chronicle"; Mr. George Gordon, V.M.H.; Mr. John Collingridge, and Mr. Edward C. A. Green, secretary of the company. Mr. R. Winfrey, M.P., proposed the toast of "The Company," and the Chairman of Messrs. Hobbies, Lim., in responding, spoke enthusiastically of the position and prospects of the business. Incidentally he mentioned that their customers numbered over 100,000. Mr. Richard Jewson, the vice-chairman, also responded. Other toasts honoured were "The Guests," "The Press," and "The Staff," the last being proposed by Dr. Hallwright, and responded to by Mr. Edward C. A. Green, and Mr. Edmonds Sears, the Editor of "Hobbies." An excellent menu was provided, and a bright musical programme added to the entertainment of the guests.

Horticulture and Forestry at the Anglo-American Exposition of 1914.—As already announced in these columns, Horticulture, Arboriculture, and Forestry are to be important departments at the Anglo-American Exposition of 1914, at the White City, Shepherd's Bush. Considerable progress was made in connection with the horticultural section on Tuesday last, when the General Committee met under the presidency of Mr. George Gordon, V.M.H., and accepted a scheme, drawn up by a sub-committee, for laying out the various beds, borders, and other spaces at the exhibition to the best advantage. Arrangements were also made for four special conferences and exhibitions, dates of which will be settled later. Mr. Kiralfy sails for the United States next week, and will get into touch with the leading nurserymen and seedsmen across the water, for the purpose of securing their assistance at the Exposition. Messrs C. H. Curtis, F. W. Harvey, W. A. Manda, and R. Hooper Pearson were added to the General Committee, and executive committees were appointed for the horticultural and the forestry sections.

Official Catalogue of Roses for 1914.—We have received a copy of the National Rose Society's Official Catalogue for 1914, and find that this new edition shows several improvements upon the older ones. The table of contents has been made much clearer, and is followed by an index of all the names of roses in the catalogue, so arranged that one may readily find the class to which a given variety belongs. The lists of roses suitable for special purposes form, once more, a very excellent feature, and we understand that in drawing up these lists the Publications Committee has had the assistance and advice of over fifty well-known rosarians resident in different parts of the country. Members of the N.R.S. are entitled to a free copy of this catalogue.

"My Camel Ride from Suez to Mount Sinai," is the title of a book written by Mr. Arthur W. Sutton, F.L.S., and recently published by Messrs. J. J. Bennett, Lim., Henrietta Street, W.C. The work is of general interest because it describes a journey made by the author in the spring of 1912 through the country which was traversed by the Israelites when they left Egypt, over three thousand years ago. Nearly a hundred illustrations serve to bring before the reader the chief places of interest noted in the Biblical narrative of the Exodus. The views of scanty desert vegetation, and of luxuriant palms at the oases, at once attract those who study plant life; while the observations of one who is so well known in the world of horticulture prove that a holiday in a desert is not without its compensations. A copy of Mr. Sutton's book has been graciously accepted by her Majesty the Queen, and we understand the whole of the proceeds of the first edition will be devoted to the funds of the Young Women's Christian Association. The author has paid several visits to the Holy Land, Egypt, and Arabia, and his lectures dealing with his travels, given before the Victoria Institute, the Horticultural Club, etc., have proved particularly instructive and entertaining.

Vancouver Island, part of the Canadian Province of British Columbia, is renowned among arboriculturists as the home of Pseudotsuga Douglasi, the splendid conifer, which, before steel became so largely used, provided the material for tall masts and flagstaffs. Other trees of commercial value find a home in this island, therefore horticulturists should have a special interest in the lecture entitled "A Ramble along the West Coast of Vancouver Island," which Mrs. Julia L. Henshaw will give at the Horticultural Club on Tuesday, December 2, after the monthly house dinner. The lecture will be illustrated with coloured lantern slides reproduced from photographs taken by the lecturer.

Official Guide to Kew. — Some time ago we announced that the President of the Board of Agriculture had appointed an official guide to conduct parties of visitors round the collections contained in the Gardens, the Plant House, and Museums, at Kew, and to point out objects of particular botanical interest. Morning parties were limited to six, and afternoon parties to twenty persons. These restrictions as to numbers are now removed, and whereas

the fee for a morning tour was 2s. 6d., and for the afternoon 1s per person, the charges henceforth will be 6d. and 3d. respectively. This considerable reduction suggests that the services of the guide have seldom been requisitioned.

Silver Medal for Ghrysanthemum Daily Mail.—Messrs. Wells and Co., Merstham, write: "In your issue of November 22, on page 889, it is reported that the silver medal offered at Edinburgh for the best new chrysanthemum was awarded us for Mrs. Tresham Gilbey. It should have read, 'for Daily Mail.' The name ticket became reversed, hence the mistake."

Pathfinding at Brentwood and Upminster. — The Upminster Parish Council is making every effort to locate and define the many pathways and rights of way in the Upminster and Brentwood district, and their efforts are being admirably seconded by Mr. J. F. Lescher, a large landowner, and chairman of the Brentwood Justices. Old maps and plans are in great request at present, and no pains will be spared to secure these country pathways for the public use.

Honey Harvest in the North.—The honey harvest this season, writes our Aberdeen correspondent, has been an exceedingly lucrative one, both from clover and heather. Clover was somewhat deficient in some districts, but there were many localities where capital crops of white clover obtained, and the bees gathered record stores. Not a few beekeepers secured from 170lbs. to 190lbs. from individual hives, and in the less-favoured districts, where the ordinary yield runs from 30lbs. to 40lbs., the average this season amounts to between 50lbs. and 60lbs. It is in such a season as the past that good management and the exercise of great care tells. One well-known expert in the north obtained from 175lbs. to 190lbs. per hive from clover within the space of six weeks, while in another instance 260lbs. was taken from a bar-frame hive of the newest type. After several more or less unproductive seasons the heather this year has yielded capital results. The beautiful weather prevailing in August and early September produced a fine flow of nectar. There were some districts where, through lack of moisture, the heather ripened and dried off quickly, but where the bees were strong the yields averaged from 70 to 80 sections per hive. The quality and flavour, too, have been very superior, and some of the honey is almost as thick as candy. The largest yields from heather are over 200lbs. per hive.

Prosecutions by the Board of Agriculture.—With the concurrence of the Lord Chancellor, the Board of Agriculture proposes to make regulations providing that in cases which appear to the Board to relate to agricultural or horticultural produce, the prosecution of offences under the Merchandise Marks Acts, 1887, shall be undertaken by the Board of Agriculture. These regulations will prescribe the conditions on which such prosecutions are to be so undertaken, and copies of the draft regulations may be obtained at the Board of Agriculture, 4, Whitehall Place, London.

Artificially Coloured Butcher's Broom is more or less familiar to most people, but its use as decorative material in the garden has been left for M. Chas. Moquet to discover. Under the title of La Franonine (Fragon is the French name for Butcher's Broom), M. Moquet suggests a new style of gardening for the purpose of securing a brilliant display in the garden during winter, when floral colouring is absent. His method is to dye sprays of Butcher's Broom the desired colour, and place these sprays thickly in the otherwise vacant flower beds, and then, as he puts it, "you get the illusion complete." Just so. We prefer to be without the illusion.

PYRUS VEITCHI.

This is a new and distinct Chinese species introduced by Mr. E. H. Wilson when collecting on behalf of Messrs. James Veitch and Sons, Chelsea. Fruiting specimens grown, from seeds sent home by Mr. Wilson, in their Coombe Wood Nursery were exhibited by the Messrs. Veitch on October 8, 1912, at a meeting of the Royal Horticultural Society, when the species received an Award of Merit.

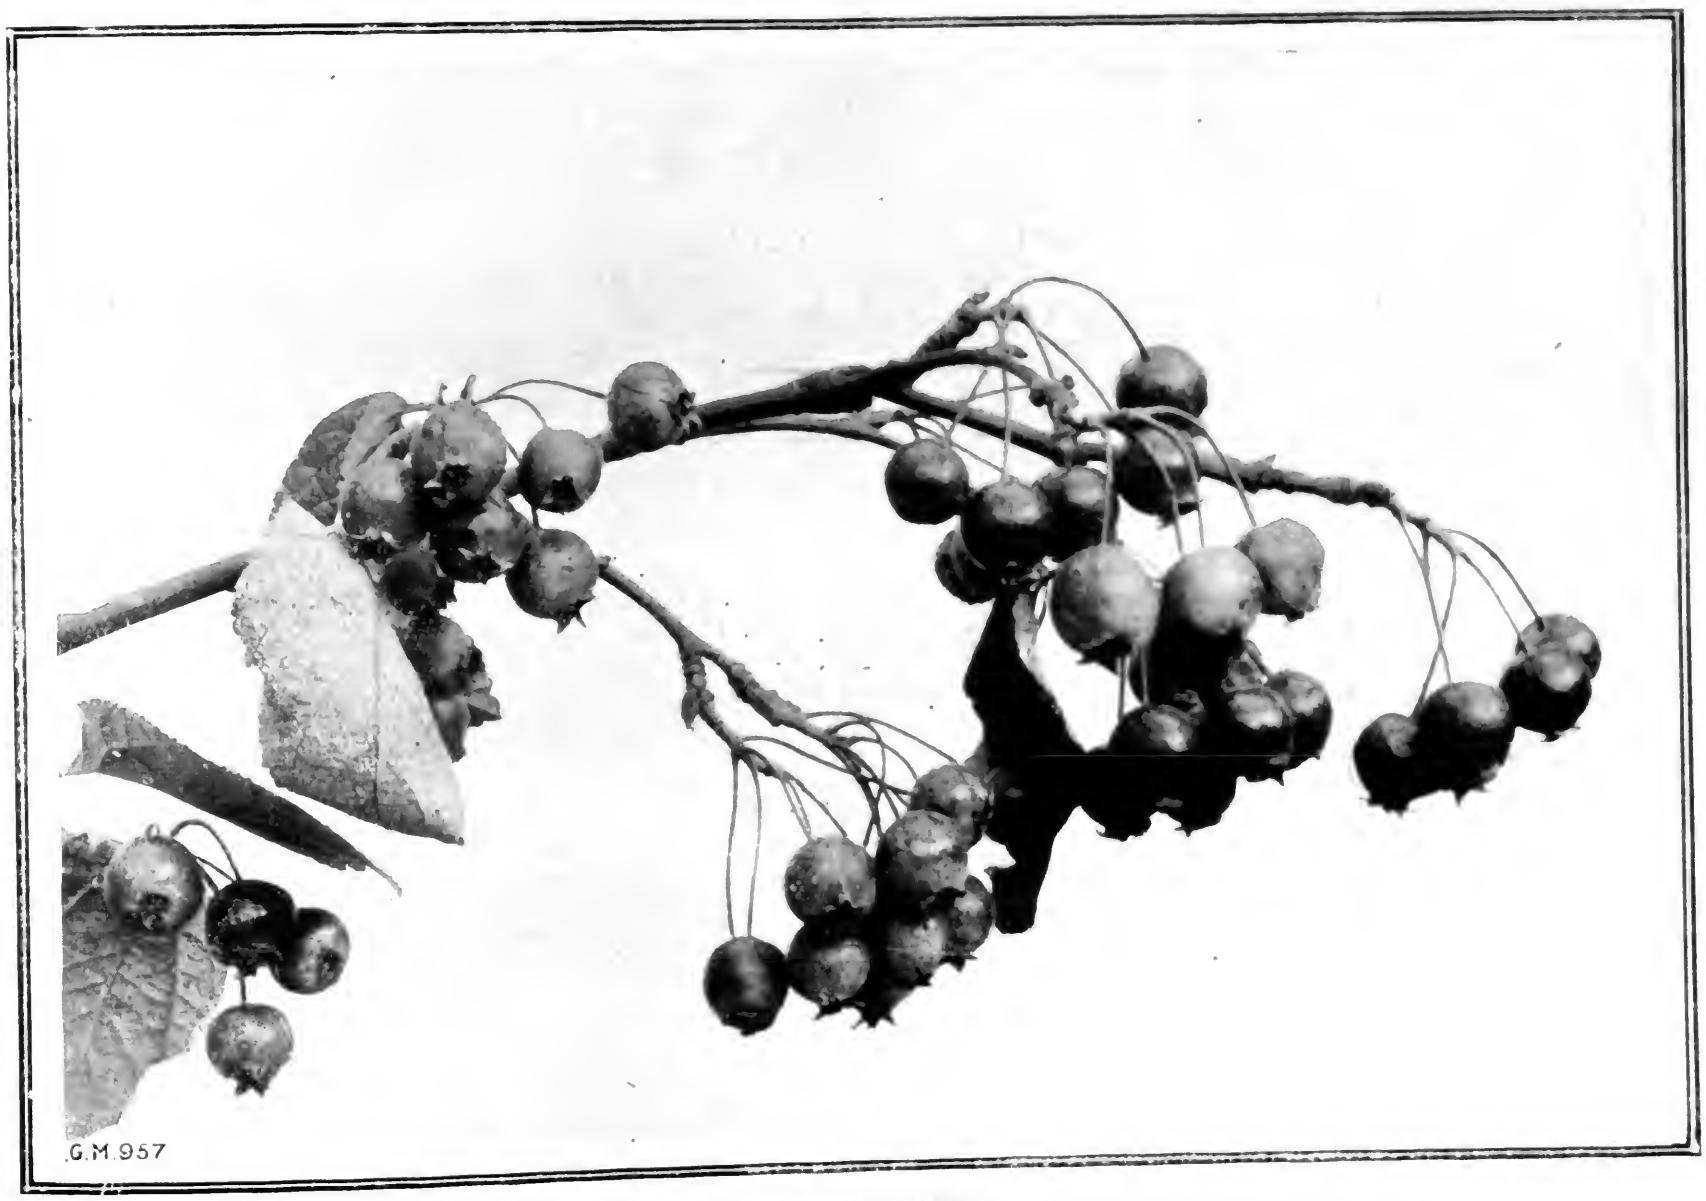
Veitch's pyrus promises to be a useful addition to our gardens as a deciduous specimen tree of moderate dimensions for the lawn and pleasure grounds. The simple leaves are ovate, and finely-toothed, dull green in summer, tinted red in autumn. The flowers are blush-pink, followed in autumn by comparatively small globular fruits, about half-an-inch in diameter. These are dark red in colour; but a close examination reveals the fact that they are speckled. The accompanying illustration successfully depicts the free-fruiting character of the sprays.

Seeds ripened in this country have been sown, and have germinated freely, so that a plentiful stock of young trees should soon be available for sale. One of the original trees is already some sixteen feet high at Coombe Wood.

When exhibited before the Royal Horticultural Society's Floral Committee the Award of Merit was given to this tree as Pyrus Veitchiana, but the name has apparently been altered to P. Veitchi, as this is the title under which it is now being sold.

A. Osborn.

Kew.



PYRUS VEITCHI.

A new species bearing an abundance of dark red fruits.

AMERICAN GOOSEBERRY MILDEW:

A REMEDY WANTED.

Some six or seven years have passed since the news was spread abroad that a new disease had been discovered among the gooseberries in Worcestershire, and not long afterwards it was found that this disease, the American Gooseberry Mildew, was present in gooseberry plantations practically all over the country. The latter discovery was, of course, made after the mildew was scheduled as a notifiable disease by the Board of Agriculture, and since then inspectors have been appointed and a large sum of money has been spent in attempts to eradicate the disease.

What is the position now? Either the measures adopted have not been drastic enough, or they are inadequate, for comparatively little progress has been made. That American mildew is not an easy thing to get rid of many of us know from experience, and I am acquainted now with several plantations which have been infected for five or six years. Every effort has been made by means of spraying and pruning to get rid of the disease, and, though these attempts may have prevented its spread, they have not been successful in eradicating it. It has peculiarities, too, that are not easily understood. For several years the summer stage of the mildew appeared first on the young shoots, but this season the fruit, in many cases, was attacked before any traces were seen on the leaves and shoots. Some people are apt to blame growers for the little progress made in stamping out the disease, but, as far as my experience goes, I have found them ready to obey the Order and adopt the methods that are recommended.

It seems, however, that better remedies are wanted than those at present known, and matters in reference to future procedure have been brought to a head by the action of the Kent County Council. At the last meeting of this authority a Special Committee reported that a year ago they decided, after anxious consideration, to recommend the Council to continue the administration of the Order, but the experience of the twelve months had been so discouraging, and growers seemed to be unanimous in their opinion that the work carried out by the Council was of little, if any, value, therefore the committee decided to recommend the Council not to appoint any more inspectors, and to terminate the appointment of the one already engaged on the work. In presenting the report attention was called to the fact that there were 3,600 acres of gooseberries in the county affected, and Alderman Quested argued that the disease would have considerably diminished if the remedies applied during the six years' administration of the Order had been effectual.

So much for the local authority. But the Board of Agriculture, on the other hand, in a letter urging the Council to continue to administer the Act, stated that so far as the Board was aware there had been no serious attempt by fruit-growers of Kent, as a whole, to free their county from infection. By way of contrast, Worcestershire was quoted in the following words: "Disease was found to be widespread and serious in Worcester before it was known in Kent, and at one time it was thought hopeless to save the gooseberry-growing industry there. Disinclination to adopt prompt measures was shown, and there was even organised resistance to the Board's Order—which the local authority conceived it their duty to enforce, however—and there was now every reason to believe that the disease in that county would be reduced to very small dimensions, and the county be freed from an expense and an embarrassment that had seriously handicapped it." Figures were given showing how the disease had decreased in Worcester and increased in Kent since 1909-10, but the arguments did not appear to have much influence on the Kentish men in arriving at their decision, and the position is interesting in regard to what will be done with American Gooseberry Mildew in the future, because the voice of such an important fruit-growing county as Kent must necessarily be listened to. It seems to be a question of either leaving growers to their own devices, continuing present methods, or, if possible, finding out something that is better.

H.

A REMARKABLE GRAFT HYBRID.

(Cratægo-mespilus Dardari).

The "Kew Bulletin" records how, in its issue of 1911, p. 267, it gave an illustrated account of this graft hybrid, and its companion of similar origin, C.-m. D'Asnieresii, was given. They both originated at Bronvaux, near Metz, from shoots borne on a tree of common medlar grafted on hawthorn. Of the two, the latter is the more beautiful as a garden tree, but C.-m. Dardari is the more interesting in having (like Laburnum Adami) the faculty of producing several kinds of growth on the same individual.

At the time the article was published the specimen of C.-m. Dardari in the Kew collection carried a branch of pure medlar and one of C.-m. D'Asnieresii; but no branch of true hawthorn, the other parent, had appeared, nor has it done so up to the present. Mr. Vicary Gibbs, however, on May 27 last, was kind enough to forward to Kew from his remarkable collection at Aldenham a flowering spray gathered from C.-m. Dardari. This spray is Crataegus monogyna—the form with hairy flower stalks, calyx-tube and deceptacle, distinguished by Beck as var. lanigera. Mr. Gibbs observed that the flowers, borne on a shoot 3 feet long, were fully open on May 27, whilst the rest of the tree had only unopened buds of the white, medlar-like blossoms characteristic of C.-m. Dardari. A shoot of true medlar has since been found on the tree.

Thus this graft hybrid shows a phenomenon, unique so far as we are aware, of one kind of tree (not as yet, however, one individual) producing four types of growth, two of which are distinct species and two of a hybrid or intermediate nature. They may be tabulated as follows:

1. Crataegus monogyna } parent species.
2. Mespilus germanica }
3. Crataego-mespilus D'Asnieresii, hybrid approaching No. 1.
4. Crataego-mespilus Dardari, hybrid approaching No. 2.

Laburnum Adami has not been known to produce more than one hybrid type of flower besides those of its two parent species (Laburnum vulgare and Cytisus purpureus) three in all.

COMPETITIONS IN THE PACKING OF SOFT FRUITS.

The schedules of the Royal Horticultural Society's fortnightly meetings on June 16, and July 14, 1914, and the Fruit Show on September 29, 1914, will contain the following class:—

Class 3.—Soft fruit, packed in an attractive manner, and so as to travel unbruised either by rail or post. The package must be sent by parcels post from the exhibitor's nearest post office, or be handed in at his nearest or most generally-used station, and delivered by the railway company, or by post, at Vincent Square, either on the Monday before the show or before 10.30 a.m. on the day itself. Under no circumstances may a competitor bring the package or send it by hand, or otherwise convey it further than his nearest or most usual post office or railway station. If sent by rail, a post card addressed to the Secretary, R.H.S. Offices, Vincent Square, Westminster, must be sent at once, saying from what station and at what time the parcel was despatched. Separate packages, or punnets, may be used inside the parcel if desired, but the whole package must not exceed 18 inches in length, 10 inches in breadth, and 5 inches in depth—all inside measurements. The packages may be of any material so long as they are sufficiently strong, but not too heavy.

The Council's desire is to obtain a really good and useful lesson in the packing of soft fruits, so as to enable them to be sent by post or by passenger train, and arrive in a condition suitable for a gentleman's table. The Council will, on June 16 and July 14, and on September 29, give special awards in accordance with the above conditions.

Market growers may compete as well as private gardeners.

By "soft fruit" is intended such as strawberries, cherries, figs, peaches, and nectarines, and not such as apples, pears, and melons, or unripe plums. Tomatoes are excluded.

FLORAL TABLE DECORATIONS.

Referring to page 866 of THE GARDENERS' MAGAZINE for November 15, I would remind Mrs. Bide that my article was directed against the style of table decorations in the exhibition tent as compared with the style in private establishments. And although at the show she mentions the awards were given to tables decorated with rustic stands, it does not necessarily mean such a style of decoration would do in a gentleman's dining-room. By "a gentleman's dining-room" I mean the dining-room in a large establishment, where, I take it, one would expect to see the highest excellence in table decoration. Money is not spared to obtain it, and I doubt whether any decorator has ever used a rustic stand in such a house as defined above. At the recent Birmingham Show, out of over two dozen exhibits, I believe three-fourths were arranged in rustic stands, and the awards had to go to displays made by their help. But a gardener has to ask himself, "Would such exhibits suit my employer?"

I have never used a rustic stand. My duties are to decorate dinner tables, etc., not to embellish a bent-metal construction. Surely your correspondent is writing entirely from an exhibitor's point of view. Private decorators have to provide a rich scheme of decoration, perfect in taste and arrangement, without the aid of tubes distributed about the receptacles used. The decoration has to be changed every day, and our hardest work is to secure fresh ideas.

Mrs. Bide says the public are the best critics. How many visitors to flower shows have seen a table laid and decorated for dinner in a large private establishment?

E. B. WISE.

Swinfen Hall Gardens, Lichfield.

NEW PLANTS AND FLOWERS.

ANGRÆCUM RECURVUM.

A lovely species, with pure white flowers borne singly on long, flexible, and drooping stems. The lip is quite flat, and each flower is three inches across. The leaves are long and leathery, in two ranks, and the stem or base of the plant sends out aerial roots from amid the fibrous ends of dead leaves, so that this basal portion looks like a little hairy trunk. The specimen shown carried thirteen beautiful flowers, and these were drawn between the leaves instead of being allowed to droop their full length. A.M., R.H.S., November 18. Messrs. Charlesworth and Co., Haywards Heath.

LÆLIO-CATTLEYA FERONIA, CHARLESWORTH'S VAR.

A splendid hybrid between C. Enid and L.-c. Haroldiana. The spike carried five very handsome blooms, each six inches wide and rather more in depth, from the tip of the dorsal sepal to the apex of the lip. Sepals and petals soft mauve-pink shaded with violet-purple; lip mauve, with a broad, frilled apex of a brilliant violet-purple shade. The throat is freely veined and shaded with deep yellow. A.M., R.H.S., November 18. Messrs. Charlesworth and Co., Haywards Heath.

DENDROBIUM LEEANUM, LANGLEY VAR.

A strong-growing hybrid with stems two and a-half feet long, bearing arching spikes of purple flowers.The sepals reflex a little, and are soft purple; the petals are of a deeper shade, and the lip is dark rich blue-purple with a darker disc of raised lines. D. Leeanum was originally raised many years ago by crossing D. Phalænopsis with D. superbiens, and it carries the chief characters of its parents, the flower being larger and broader than in D. superbiens, but not so rounded as in D. Phalænopsis. A.M., R.H.S., November 18. Messrs. Flory and Black, Langley, Slough.

BEGONIA SYROS.

One of the newest of the winter-flowering varieties, and derived from B. socotiana and a copper-coloured tuberous begonia.Of excellent habit, sturdy, and carrying about seven flowers on each semi-drooping spike, it is remarkably free flowering, and as the colour is light orange-tinted buff, the plant is most effective. A.M., R.H.S., November 18. Messrs. Jas. Veitch and Sons, Chelsea.

COLUMNEA OERSTEDIANA.

A beautiful and rare plant shown in magnificent condition. It has long, wiry stems with opposite, fleshy, ovate, small, shining green leaves, and bears its flowers singly from the leaf axils. The calyx and the flower are alike rich and brilliant orange-coloured. The individual flowers are two and a-half inches to three inches long, with a two-lipped mouth, the lower lip narrow, and the upper lip tribolate, its central lobe quite broad. In the throat there is a tinge of yellow in the orange. C. Oerstediana is a native of Costa Rica (see p. 877). F.C.C., R.H.S., November 18. Sir Trevor Lawrence, Bart. (gardener, Mr. W. Bain), Burford Lodge, Dorking.

CYPRIPEDIUM KENTORE.

A very distinct and handsome hybrid from C. Fairieanum; C. Cambridgeanum being the second parent. The dorsal sepal has a white margin and white ground, but the whole of the centre is heavily veined and shaded with dark, rich claret-purple, and this colour is also seen on the deflexed wavy-margined petals, in conjunction with green shading and white tips. Lip brilliant purple-brown. A.M., R.H.S., November 18. Messrs. Armstrong and Brown, Tunbridge Wells.

CYPRIPEDIUM CYCLOPS.

A large and bold hybrid with a rounded flower, the dorsal sepal a little over three inches wide, and the flower four and a-half inches across the petals. The dorsal sepal is light green, with purplish spots of various sizes, and a wide, white margin all round the upper portion. Petals green, shaded with brown, and with a narrow purple line and purple spots; lip green and purple-brown. C. Actæus and C. Alportensia were the parents of C. Cyclops. A.M., R.H.S., November 18. Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury.

ANGRÆCUM RECURVUM.

A beautiful white-flowered species. A.M., R.H.S., November 18. Messrs. Charlesworth and Co., Haywards Heath.

MILTONIODA HARWOODI, THE SHRUBBERY VAR.

A charming form of the pleasing hybrid between Miltonia vexillaria and Cochlioda Noezliana. The flowers are flattened, the sepals and petals bright red, the lip deep reddish-rose, and the column and disc golden-yellow. The little plant exhibited carried a spike of seven expanded flowers and two buds. A.M., R.H.S., November 18. Messrs. Armstrong and Brown, Tunbridge Wells.

CHRYSANTHEMUMS.

Mary Morris.—A splendid single-flowered variety with large-sized blooms, each having about three rows of well-arranged reddish-terra-cotta florets, surrounding a dark yellow disc, that, in turn, is surrounded by a narrow bright yellow zone. The specimen showed carried a few over fifty flowers. A.M., R.H.S., November 18. Mr. Thos. Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, Addlestone.

Maud Louisada.—A Japanese variety of full exhibition size. The flowers are broad in build, with long, medium-sized florets, which curl and intertwine in a charming manner. The colour is silvery-mauve, with a paler reverse. It should make a popular exhibition variety. H., a.; F.C.C., N.C.S., November 17. Messrs. H. J. Jones, Lim., Ryecroft, Lewisham.

Miss Willis.—A charming single variety, good either disbudded or in spray form. The colour is white, slightly shaded pink. V., 2. a; F.C.C., N.C.S., November 17. Mr. H. Reddan, West Wickham.

Mrs. H. Bean.—A large single variety, with four rows of petals, making up a finely-formed flower. Commendation, N.C.S., November 17. V., 2, a.; Mr. H. Reddan, West Wickham.

Gladys Jones.—A striking single variety, with tubular florets which open flat towards the ends; best described as rosy terra-cotta. V., 2, a.; Commendation N.C.S., November 17. Mr. P. Ladds, Swanley

Mr. L. Smith.—A single variety, of good build, with two rows of florets, a deep rich rose colour. V., 2, a.; Commendation, N.C.S., November 17. Mr. F Humphries, Shoreham.

Mrs. Lawrence.—A very fine single variety, rich rosy-pink, with a small white zone; suitable as a disbudded flower, or in spray form. V., 2, a.; Commendation, N.C.S., November 17. Mr. J. Lawrence, Shoreham, Sevenoaks.

Holyport Pride.—An anemone variety exhibited in the competition for the best seedling of 1913. The colour is rosy-mauve, and it was awarded 65 points out of a possible 100. Commendation, N.C.S., November 17. Mr. Broom, Holyport, Berks.

THREE GOOD ROSES.

Now that the planting season is again with us, I would like to draw the attention of rose-loving readers of THE GARDENERS' MAGAZINE to three roses which have been especially good with me during 1913. My soil is not the heavy yellow loam so much belauded by many rosarians, but is a deep, dark soil of a light nature.

The first of my varieties is Miss Cynthia Forde, deep pink, with the inside petals flesh-pink. This is a sturdy and free-branching variety, mildew-proof here, and (a matter of importance in a bedding rose) it opens its flowers fully, and retains its colour well. The blooms are of good size and shape, and sufficiently full to build up a bloom fit for any exhibition. Mrs. C. E. Allen is my second variety, and in this the colour is pale orange, shading to straw, with ochre tints. This is a good bedding rose, as every branch carries one or more flowers, which are beautiful in all stages of development. It is a rose that lasts well, and is delightful for personal wear. My third successful variety is Leslie Holland, a fine scarlet-crimson rose, with darker shading. This differs from the two former in its habit of growth, as each shoot is upright, and blooms at the tips. About 18 inches high, it flowers continuously, does not fade in the sun, and is therefore a fine hot-day exhibition rose; moreover, it does not flag, like so many roses do, when placed in an exhibition box. To amateurs who have a soil that is not cold I can strongly recommend these three fine varieties. They have been shown by me every time I exhibited in the past summer, and helped me to win half a dozen first prizes. To-day (November 12) I have cut flowers of each variety, and the perfume of Leslie Holland is charming even at this late date.

HAROLD NEWTON.

Winterley, Sandbach.

The Mountain Feather Fleece.—The botanical name of the plant, which has such a pleasing, popular one, is Stenanthium robustum. It is a flower which has quickly come to the front, and is likely to be better appreciated when its preference for moisture is recognised and considered when it is being planted. It is very handsome when in a moist place, growing to as much as four or five feet high in some places, and giving handsome plumes of drooping feathery, fleece-like blooms, which have been well described as "making a snowbank of bloom." One writer hardly does justice to it in a remark in which he likens it to a certain ornament connected with obsequies; but the plant is really a very beautiful one when in a moist place by the side of a stream or in a bog. It is increased by division, and is now sold at a moderate price for a plant of its character.—S. A.

AMONG THE ROSES.

This is a very busy time with rosarians as planting should be in full swing. It will be well to remember the great harm often done by excessively treading the ground when it is wet. If planting cannot be delayed use planks to walk upon, and place dry, prepared soil in contact with the rose roots. This will readily work among the fibres, and assist in early root formation. Fresh manure of any kind should never come into contact with the bare roots, but be well intermixed with the soil, so that the new roots can find it for themselves when they are active next spring.

Standard and pillar roses must be made secure against damage from wind, and there is no reason why this should not be done at planting time. If this precaution is neglected the swaying causes a smooth hole to form at the base of the stem, which not only holds water but leaves the most vital spot unprotected.

As most of our extra-vigorous roses need closer pruning than those of normal growth the first spring after planting, we might as well cut away a goodly portion of this superfluous wood at the time of planting. In many cases semi-pruning might be practised with advantage, as it reduces the strain upon the unestablished roots, and keeps the lower buds, or eyes, in better condition.

Mulching established roses is pretty general at this time of the year, but I protest against overmuch manure being placed close to the base of the plant with an idea of protection. It is far better and safer to draw some of the surrounding soil to this part, which will always secure the base and the valuable lower eyes from harm.

When the work is finished the plant should appear as though growing from a good-sized mole-heap. This soil will not only keep away frost, but keep the base of the plant dry. Quite the opposite is the case when a quantity of manure lies in contact with the stem base, as this retains the moisture, and thus renders frost more harmful.

How to mulch and what to use for the purpose depends upon the class of soil and material available. Several hints upon manures for roses have appeared from time to time, and I merely give this reminder so that they may be put to the best advantage.

While dealing with protection, I may say that it is not nearly so much practised as was once the case. Still, it is advisable to have something ready in view of severe weather. One of the readiest means is provided by pieces of fir, gorse, and laurel that may be cut from hedges and saved for the purpose. The twiggy branches of birch, beech, and hazel are also very suitable. These are quickly inserted in the ground around and against any of the more tender varieties, and afford great protection. They might also be fixed in the form of a shelter hedge upon the exposed side of beds and borders.

I have very little to say in favour of straw, hay, and loose litter that have a tendency to blow away when most wanted, or else fall to the ground and retain any moisture that may be present. In fact, this class of protection is apt to do the same harm as overmuch wet manure around the base of our plants, and it is generally admitted that frost and wet combined are more harmful than frost and dry weather.

ROSARIAN.

HABRANTHUS PRATENSIS.

The proper name of this handsome bulbous plant is Hippeastrum pratense, but it is generally known in gardens as Habranthus pratensis, although occasionally met with as Amaryllis pratense. A native of the hills and plains of Chili, it has proved amenable to cultivation in some parts of the United Kingdom in the open, and is also highly suitable for growing in pots in a cool house. It is cultivated in the open air with much success in the Eastern Counties of England, and in the gardens at Westwick it is a great success. The writer saw it in Ayrshire this summer, well established in the border, and cultivated without any protection. It is a very handsome Amaryllid, with leaves about a foot and a-half long, and bearing on stems, a foot or so high, handsome, brilliant scarlet, bell-shaped flowers in summer. It has, within recent years, been grandly shown at the London exhibitions. It succeeds well in pots in the cool house, giving it a period of rest after flowering, and potting in soil composed of loam, peat, and sand. It is, however, very desirable that H. pratensis should be grown more frequently in the open, and it may be planted in a warm, sheltered, well-drained, sunny border in loam, leaf-soil, or peat and sand, at a depth of from six to eight inches. A covering of ashes or dry litter may be placed over the place the first winter, but in after years it may be dispensed with. It is not possible to predict success in every garden, but it is safe to say that many places would be beautified by the brilliant flowers of this plant were it attempted and treated in the manner suggested. S. A.

LATE-FLOWERING SHRUBS.

Often, when walking round a garden, attention is drawn to some unusual plant, or the unusual manner in which it is growing. I have before remarked how well all kinds of flowering shrubs bloomed in the spring and summer of this year, but I do not ever remember those which bloom in the latter part of the season producing such a wealth of flowers before. Here the myrtles growing in the open were so covered with flowers that one could scarcely see the foliage, and at the present time the various osmanthuses are loaded with their small, sweet-scented flowers. The most interesting shrub, however, at the present time (November 15) is Berberis Darwini. This is now in full bloom, and has been for some days past, and though the racemes are not quite so long or of such a deep colour as in spring, they are very beautiful. Flowering at this season of the year can be accounted for, in a measure, by the dry weather during the summer months, for between May 14 and September 1 only three inches of rain fell, so that the land had become very dry. September and October were two showery months, with warm night temperature, which no doubt caused the most prominent buds to burst into bloom after the long spell of dry weather, with the result that we have now a second crop of flowers.

I noticed a lilac bush the other day with the crown buds all bursting, and the spikes of flowers just showing themselves, while those on another plant were just unfolding their young leaves. I could have understood this had the shrubs been recently transplanted, but those in question have been in their present position for several years. No doubt the late mild weather has had much to do with this abnormal blooming.

H. C. PRINSEP.

Gloucester.

A PLEA FOR NERINES.

The nerine is an autumn-blooming Cape plant, which should appeal to all lovers of bulbous flowers. Once understood, its requirements are few, therefore it should be far more grown than at present. Any amateur having even a small amount of glass to spare should secure and cultivate a little collection of nerines, and he will be more than repaid by the charm of the gilt-spangled flowers, which continue in succession right through the dull autumn months.

The ease with which nerines can be hybridised, or cross-fertilised and grown from seeds, is remarkable, and if careful records are kept the fascination of the seedlings when they begin to come into flower at about the third year from sowing is something delightful to count upon and look forward to.

The first of the species to open, and perhaps the handsomest of all, is N. Fothergilli, which bears umbels of large scarlet flowers, borne erect, and which glitter in the sun as though gold-specked. N. sarniensis (or N. corusca) comes a little later, bearing heads of orange-scarlet flowers. The only pure white natural kind with which I am acquainted is N. flexuosa alba, believed by some to be a white form of N. crispa (or N. undulata); the last-named is rather a poor flower, and scarcely worth cultivating for its own sake, though I have seen some very pretty hybrids from it. N. Planti is a good nerine, the flowers crimson-scarlet, and the spike well-formed; I imagine it to be a hybrid. Later on come N. Manselli and N. Bowdeni, with pinkish flowers, the latter being, perhaps, the largest flowered of all.

But to add to these there are now the numerous hybrids raised during the last twenty years by Mr. H. J. Elwes and others, some of which are gradually beginning to find their way into the market, though it should be borne in mind that a long time is needed to work up the stock of a nerine, increase from offsets being in most cases a very slow process. This was brought home to me the other day when I was looking at the stock of a nerine raised about twenty years ago, of which I happen to be the fortunate possessor. It consists only of seventy bulbs and small offsets, all told.

The nerine would gain in popularity, to my thinking, if it were more shown by the trade at the London shows, as well as at provincial autumn shows. Beyond an occasional display made by Mr. Elwes, and peripatetic exhibits by Messrs. Barr, Veitch, and one or two others, I think that Mr. G. Reuthe, of Keston, is about its only regular exhibitor, and on recent occasions I have not failed to notice in front of his stands a foregathering of those who are interested in these things.

I started my collection of nerines about ten years ago, and at once began to cross-breed them. About as soon as my first seedlings were beginning to flower the whole lot was visited by a severe attack of mealy-bug, which put the plants into bad health. I tried various remedies without success, until someone recommended methylated spirit. We went carefully over every plant with this, my man and I, using a camel-hair brush, and working between every leaf and scale, until now I have the collection clean — at least, I hope so, and I touch wood as I write this!

Seedlings that are coming into flower for the first time at the moment are principally from crosses made between N. flexuosa albo, N. sarniensis, and N. Planti, and there are some very charming things among them. N. flexuosa alba (seed) x N. sarniensis (pollen) is giving pretty rose-pink flowers, with a darker line down the centre of each petal; while the reverse cross has produced some very handsome scarlet-crimson flowers, shading to white in the centre; in both cases the undulating petal of N. flexuosa alba is much modified, but is just in evidence.

Next year's seedlings should be still more interesting, as the crosses were much more varied, and as time goes on the excitement as to results may be expected to increase.

In most cases we leave our nerines in the same pots for three years, and after that period divide and repot them, while in a dry state, in August. As is well known, the nerine needs to be well watered during winter to make good and strong foliage and sturdy bulbs, and an occasional dose of some liquid manure is not inadvisable. As the leaves fade away in late spring the plants should be kept perfectly dry in a frame or greenhouse, close to the glass, until they show the first signs of flowering or of growth, when they may be actively started by dipping each pot into a pail of water or otherwise thoroughly moistening the soil.

A word or two as to hybridising and seed-sowing. The pistil of the nerine is prominently visible between its six stamens, and the pollen from the anthers of another variety can be transferred to the stigma by means of a camel-hair brush. I always keep a record of the varieties or species used, and this adds immensely to the interest of seedling-raising. The seeds are ripe as soon as they are easily detachable. There are some folks who delay gathering seeds until they fall, thinking that they will wither and harden; this is a mistake, for they remain green and fleshy to the last. After gathering, seeds should be sown as soon as possible in pots or pans, using a fairly light compost, and covering the seeds with about half or a quarter of an inch of finely-sifted soil. We never dry off our young seedlings like we do the fully-grown bulbs, but keep them growing steadily all the time.

A complaint is sometimes made that the nerine is a "naked" flowering thing, coming into bloom before the leaves are properly developed; but I would like such critics to see an exhibit of finely-flowered plants, carefully interspersed with adiantums and other ferns, such as is occasionally set up by Mr. Elwes at the Royal Horticultural Hall. In all my floricultural experience I have seen no more charming sight.

F. Herbert Chapman.

Rye.

CHRYSANTHEMUM MARY MORRIS.

A handsome, free-flowering, single variety with reddish, terra-cotta blooms. A.M., R.H.S., November 18. Mr. T. Stevenson, The Gardens, Woburn Place, Addlestone. Raised by Mr. T. Page, Hampton. (See New Plants.)

THE TWEED VINEYARDS, CLOVENFORDS.

Nestling among the hills, about three miles from the ancient town of Galashiels, is Clovenfords, and close by the railway station, sheltered on all sides, are the Tweed Vineyards, established nearly half a century ago by the late Mr. William Thomson, after he had for many years been head gardener to the Duke of Buccleuch, at Dalkeith Palace. The place is aptly named Tweed Vineyards, for grape-growing has all along been the chief speciality of the firm. In the early days pineapples were also grown, but the time came when pine-growing had to be relinquished in order to meet the growing demand for the grapes that readily won a widespead reputation for superior quality.

A PORTION OF THE TWEED VINEYARDS, CLOVENFORDS.

The houses are lofty, well built structures, and the vines are full of health and vigour, clean, and free from either disease or insect pests. One vinery 200 feet long contains about fifty vines of Muscat of Alexandria, which are thirty-six years old, and they produced this season a magnificent crop of about 700 bunches, weighing from about two pounds to over six pounds per bunch. Another grape of high quality that is grown in considerable quantity is Duke of Buccleuch, which, when well finished, is of bright amber colour, and exceptionally rich in flavour. Buckland Sweetwater is grown, but it has not the quality of the last-named. As might be expected, Black Hamburgh is largely cultivated, and the crop this season was somewhat above the average in weight. Appley Towers and Lady Downe's are represented by a number of strong vines in full bearing, but the variety that is grown in greatest quantity of Gros Colmar. Its chief points are good cropping qualities, handsome appearance, and a skin texture that enables it to travel without damage. The flavour of Gros Colmar, when well grown and finished, is superior to that of other large-berried black varieties, and as the thousands of bunches grown at Clovenfords are readily disposed of, the system of cultivation adopted obviously provides the necessary quality and "finish."

It is quite apparent to anyone who carefully notes all there is to be seen in the establishment, that a wonderful amount of care and attention is bestowed upon the vines, and minute details are not overlooked. Mr. D. Calderhead, who has had the care of the vines for about thirty years, knows the peculiarities of each variety, and thus one finds that in some cases new wood is constantly being laid in to replace old, and the temperature at finishing time is regulated to suit the variety in the house. These, as every grape grower knows, are points which have a direct influence on flavour, and one is not surprised to learn the Clovenfords grapes are in such demand among the leading fruiterers of Edinburgh and Glasgow that the whole crop, running to about 15,000lbs. per season, is disposed of without having to market any in England, although in the earlier years of the firm's existence goodly quantities were sent to London. One variety that deserves mention, but one not so often met with as its merits would warrant, is Cooper's Black. Some of the bunches of this grape are very handsome, and, having put the flavour to the test, we can testify to its thoroughly good quality. It makes large-berried, high-shouldered bunches, which carry rich bloom; and, although the skin is not tough, the fruit travels well.

A system has for many years been in vogue at Tweed Vineyards of maintaining its staff of assistants by means of young journeymen gardeners, who, after a stay of a couple of years or so, have gained experience that enables them to take positions in good private establishments, where they find their acquired knowledge of grape culture a useful asset. Thus it is that throughout Scotland, and also in a good many places in England, one meets men who can look back with satisfaction to a pleasant and profitable sojourn at Clovenfords.

It must not be supposed that grapes alone are grown here, for in few nurseries are palms grown in such quantities. Several houses are devoted exclusively to them, and they are to be seen in all ages and sizes, from the tiny seedling just starting into active growth, to tall, stately specimens, ten, twelve, and more feet high, the demand for the larger sizes being constant, while plants in five-inch pots are disposed of in huge quantities. Kentia Belmoreana and K. Fosteriana are always useful, and the extremely beautiful Phœnix Roebelini has of late years become very popular, and it receives commensurate attention in these nurseries. Araucaria excelsa is another decorative plant that the Messrs. Thomson do well, and the crested nephrolpis, adiantums, Asplenium nidus, and other ferns are to be seen in large quantities. Tomatoes also are largely grown for market, and meet with a ready sale in the neighbouring towns.

At one time the late Mr. Wm. Thomson, jun., son of the founder of the firm, and father of Mr. W. H. Thomson, the present managing director of Messrs. W. Thomson and Sons, Lim., possessed an extensive collection of orchids, in which he took a very keen interest, but at present these plants are confined to batches of cœlogynes, cypripediums, odontoglossums, etc., for the supply of cut flowers.

Readers of the THE GARDENERS' MAGAZINE are familiar with the name of Thomson's Vine, Plant, and Vegetable Manure, and not a few are fully acquainted with its great value as an aid in the successful culture of both fruit crops and ornamental plants. Consequently there is full justification for a reference to it, because the health and productiveness of the grapes, melons, cucumbers, and tomatoes, and the luxuriant growth of the palms bear excellent testimony to the value of the manure, which is regularly used for all crops grown in the establishment.

VISITOR.

COLOUR IN GRAPES.

I have rarely seen better-coloured Muscat of Alexandria and Gros Colmar grapes than those staged at some of our big shows this autumn. The deep black colour of the last-named did not particularly surprise me, but the rich amber of the muscats did. Large, shapely bunches were exceedingly well finished, and not on one side of the bunch only, but all round. The finish was of a higher order than is usually seen, as very few berries showed signs of shrivelling. Madresfield Court, too, has been superior in many instances this year, the berries being large and well finished. It is often the case that large bunches of Gros Colmar are wanting in finish, but this year all I have seen have been perfect in this respect, and consequently of good flavour for that variety.

Bunches of muscat grapes, two feet or a little more from the roof glass, not too densely covered with foliage from the thinning stage, and as fully exposed as possible after the berries soften for ripening, have a richer amber colour than those kept too close to the glass and suddenly exposed after the seeds have hardened. Further, I have noticed that muscats grown in vineries in an open quarter colour better than others in a very enclosed place; also that those in high structures finish more satisfactorily than bunches in low houses, though why this should be is not an easy matter to determine.

In one district, where chalk abounds in the soil, the muscats are of very high quality every year, while the black grapes grown there are coloured with difficulty.

Gardeners often have many conditions to consider, and many obstacles to overcome before they can produce perfect grapes. Of course, we must not forget the fact that light cropping has a great deal to do with the finish of a bunch of grapes, and also that proper time must be allowed for ripening, therefore these two points must always receive full attention. G. B.

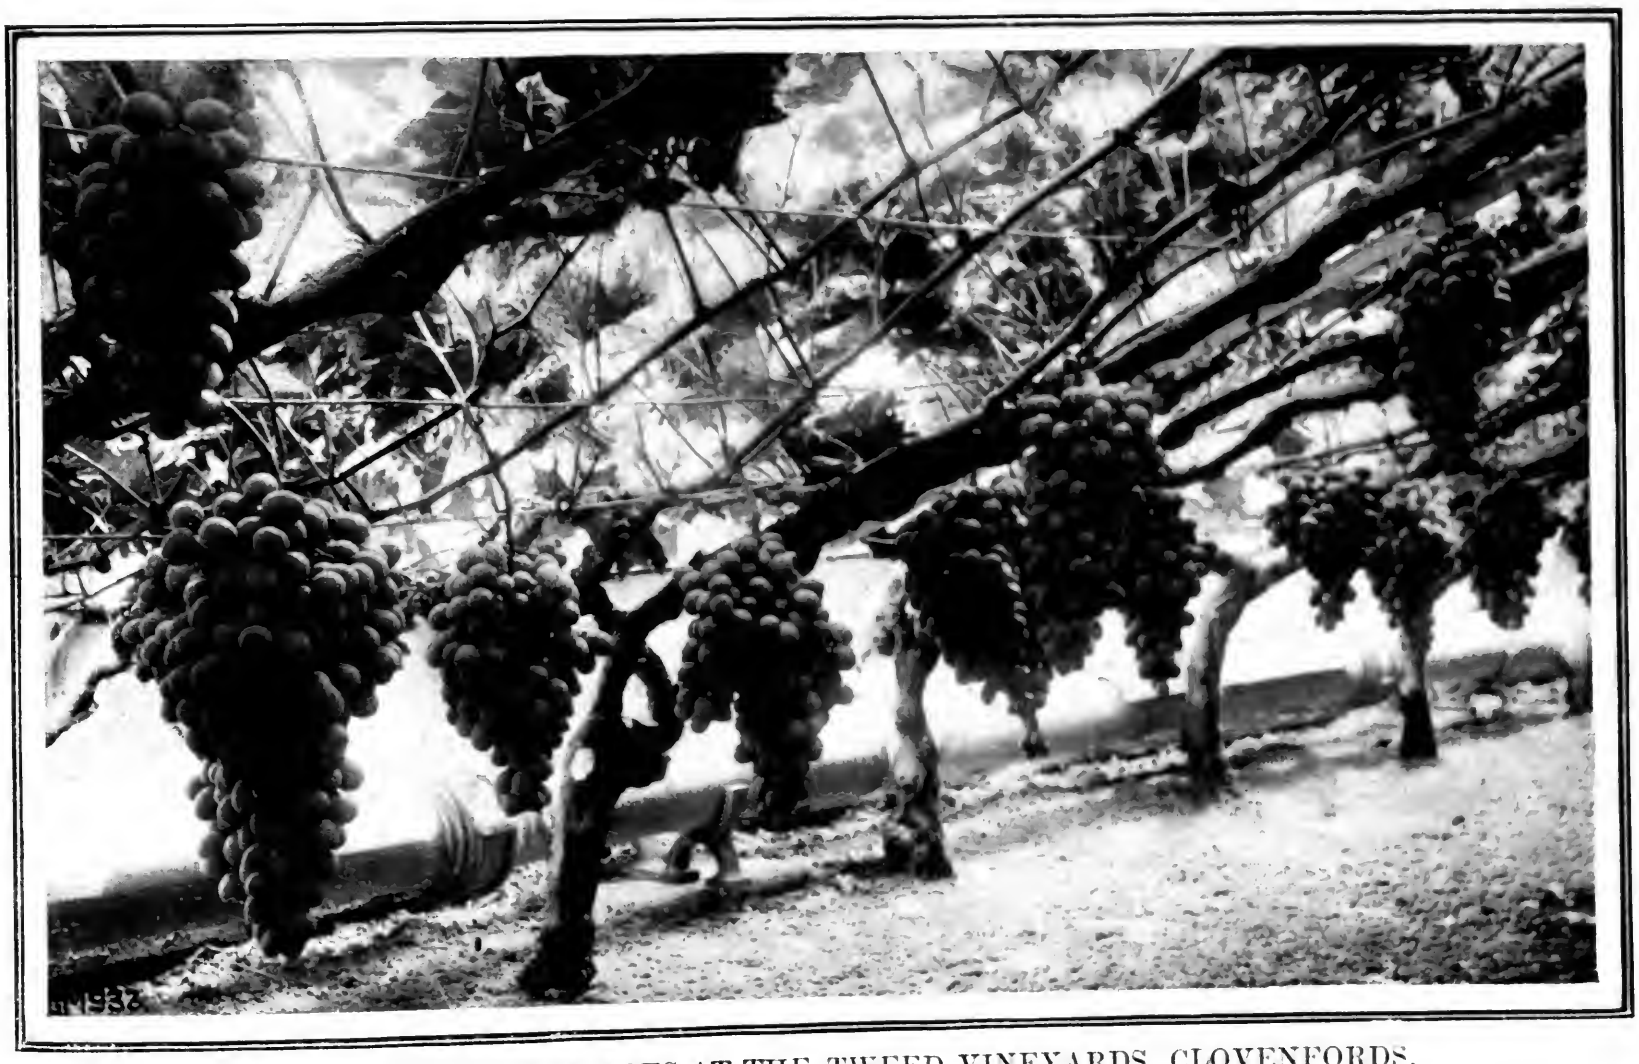
NOTES ON PEARS IN 1913.

It may be said there were no pears to make notes about in 1913, but most of us had a few fruits. The pear is one of the most capricious of fruits, and probably no other fruit reflects the peculiar conditions of a season to such an extent, and not only of the current season, but sometimes of the preceding one as well. On April 12, 1912, we had six or seven degrees of frost, when most varieties were in full flower, and yet it was an extremely good pear year. On April 13, 1913, when the blossom was not quite so far advanced, some of the later-flowering varieties not having begun to open, there were six or seven degrees of frost, with the results we all know. It seems a reasonable assumption that the remarkable summer of 1911 so ripened the fruit buds that they could withstand the effects of the frost, and that after the cool, damp summer of 1912 the blossom was not so strong, and succumbed to a frost of similar intensity. It is good to see the trees covered with fruit buds this autumn, and the resulting crop will be interesting as showing whether the fine autumn of this year has made up for the dull summer in maturing the fruit buds.

There is no doubt the later pears suffered from the general lateness in maturing. In 1912 nearly all pears were ready to gather by the third week in October, and so had time to finish; but this year they were at least a fortnight later, and as nearly all pears begin to shed their leaves at the end of October, irrespective of the earliness or lateness of the season, they did not have time to finish. I gathered some Oliver de Serres and Glou Morceau on October 30, and they were very hard to remove. Referring to the latter pear, I had an interesting illustration of the varying hardiness of the blossoms of different varieties last spring. In 1909 I put some grafts of Winter Nelis and Glou Morceau on the top of an old Marie Louise. Both varieties were in full flower at the same time last spring, the sharp frost of April 13 coming just before the blossom opened. I picked 26lb. of fruit from the Glou Morceau grafts and one specimen from the grafts of Winter Nelis. It could scarcely be a question of pre-potency of pollen, for last year both varieties fruited equally well, and there are no other varieties very near them which flower quite at the same time, as both of them are exceptionally late.

Birds have been extremely troublesome, as well as wasps, and probably most of the September and October varieties were gathered earlier as a consequence, though some of the later sorts escaped, owing to their green or russety appearance, or general lack of attractiveness to birds. A good pear is worth a good price considering the care necessary before it is put on the table in perfect condition. Large specimens are always worth the protection of muslin bags, as they are then secure against both birds and wasps; but where there is a large crop of ordinary fruit the paper-collar system is all the protection which can be given, failing the enclosure of the tree in a net, which is the most satisfactory way where wasps are not the trouble. A little care in protecting the fruit and in mulching the trees has been better repaid this year than in most years, partly owing to the value of the fruit in a poor pear year, and partly owing to the response during the long growing time, fruit swelling more in October in some cases than in either August or September. Alger Petts.

Essex.



VIEW IN ONE OF THE HOUSES AT THE TWEED VINEYARDS, CLOVENFORDS.
Showing heavy bunches of Muscat of Alexandria grapes growing quite close to the ground.

Plumbago rosea.—If treated as previously recommended the earlier batch will now be flowering, and will prove useful for the decoration of the conservatory if the structure is kept moderately warm, while for table decoration associated with light foliage it is one of the most useful subjects we have. Where pinching was continued until October the plants will be at their best about Christmas, and, with care, will last several weeks longer if required. A little plant food may be given weekly until the colour of the flower is seen, when only clear water should be applied.—H. Prime.

MIXED FLOWER BORDERS.

Mixed flower borders are of many kinds, and thereby show that there is a great diversity of taste in arrangement, and considerable difference of opinion as to the position which should be assigned them in the general scheme of garden decoration. In many instances these borders are planted with so much skill and taste as to present a most attractive appearance from the earliest stage, and retain their charm over a surprisingly long period. In some instances the effect produced is of a delightful character, but of short duration, owing to a failure to fully appreciate the importance of continuity in the plants selected.

On the other hand, there may be seen in a few gardens borders so wanting in taste and attractiveness as to suggest that they had been regarded chiefly as receptacles for the surplus plants, rather than as an essential part of a decorative scheme. Probably those who plant their mixed borders with such oddments that may remain at the close of other planting operations have a difficulty in raising stocks of the several kinds equal to their requirements; but that cannot be accepted as an excuse for unattractive mixtures where taste and beauty should attain a high degree. Difficulties associated with the flower garden, as in the case of all others, should be regarded as existing only for the purpose of being surmounted. The best means in this case of overcoming difficulties would be a more careful estimate of the number of plants of the several kinds and varieties required for carrying out the general scheme, which should be carefully considered and decided upon early enough for the plants to be raised under the best possible conditions.

If those who so far fail in their appreciation of mixed flower borders as to consider them undeserving of prominent positions, or of great care in planting are, comparatively speaking, few in number, they are more than sufficient to justify attention being called to the fact that so far from this being the case, such borders may be made one of the most delightful features of the flower garden. The mixed flower borders to which reference is now being made are not areas devoted to selections of hardy perennials or tender plants, but borders in which both hardy and tender kinds are grown in association.

The magnificent border, herewith illustrated, that flanks the northern half of the promenade at Hampton Court, may be taken as one of the finest examples that could be had of such borders. A border of this description is capable of considerable modification, for, while admirably suited to its environment in the great gardens of which, annually, it forms so delightful a feature, it may be adapted to the conditions that obtain in gardens of quite moderate dimensions without suffering any lack of interest and attraction. As so well shown in the illustration, the plants were arranged in rather large and somewhat irregular groups, and it will be seen that they chiefly represent subjects generally utilised for beautifying the flower garden during the summer months.

The value of mixed borders is not, however, limited to the summer—or, indeed, to any one season—for, by means of suitable selections of plants and careful management, they may be made to contribute liberally to the attractions of the garden from the opening days of spring until the autumn season is within a measurable distance of its close. We have ample evidence of this at Hampton Court, where the border glows with colour from the time of early tulips until the latest of the chrysanthemums are despoiled of their beauty by the unfavourable climatic conditions usually associated with drear November.

A BEAUTIFUL FLOWER BORDER AT HAMPTON COURT,
Composed of both tender and hardy plants.

The chief aim in management should be to maintain a continuous display of flowers over the longest possible period; and closely following this should be the endeavour to so arrange the subjects that they will be either in harmony with, or present a pleasing contrast to, each other. There is not, however, so much risk of unsatisfactory effects from weakness in the association of colours as is commonly assumed to be the case, because the leaves in their various shades have a remarkable effect in obliterating or toning down any defects arising from a failure to strictly observe the rules governing colour contrasts.

The arrangements for the production of a display of flowers during the spring

months should have special attention, and if this be given it will be found that bulbous plants must be largely employed in association with various fibrous-rooted subjects which flower from March until May, As it may not be possible to leave any considerable proportion of the bulbs in the ground long enough for the leaves to complete their functions, and the bulbs to attain their full development, the cheaper kinds should be taken full advantage of.

As in the case of the Hampton Court border, the several subjects should be arranged in irregular and relatively large groups, and it will greatly simplify matters if the spaces are marked out and the names written in on a plan before the planting is proceeded with.

For flowering early in the spring, eight or ten varieties of the Dutch tulips that bloom in succession to the Van Thols should be selected; and with them a similar number of daffodils, and half a dozen or so of hyacinths. For associating with the bulbs the single and double arabis, the perennial candytufts, Alyssum saxatile and its varieties, the compact-growing forms of Silene pendula, forget-me-nots, and wallflowers will be most useful. During May the chief display of flowers will be produced by the Cottage and Darwin tulips and the fibrous-rooted plants, and it is a very good practice, when it is not desired to keep the tulip bulbs for planting a second time, to arrange the Dutch and May-flowering tulips in the same spaces. Especially is this practice useful in the case of small borders in which it is desired to have as great a diversity of form and colour as possible.

It need hardly be said that when two sets of tulip bulbs are planted in the same area, the bulbs of each should be 60 or 70 per cent. farther apart than when grown separately. Should the leaves of the tulips become much crowded when the earliest of the varieties have flowered, cut these latter close to the ground; and when it is not necessary to do this, remove the flower-stems low down as soon as the blooms are over.

There is hardly any limit to the plants that may be utilised in the production of colour effects in the mixed border during summer. To mention but a few, there are the ivy-leaved and zonal pelargoniums, Calceolaria amplexicaule and C. Burbidgei, the former being unsurpassed in attractiveness when supported by neat stakes; lantanas, heliotropes, fuchsias, dwarf cannas, plumbagos, swainsonias, fibrous-rooted and tuberous begonias in variety, verbenas, antirrhinums, pentstemons, celosias, violas, and plants with grey and dark foliage. Some of the more beautiful annuals may be utilised with advantage, but as these do not continue in bloom throughout the season, it is necessary to arrange for them to precede or follow other short-lived kinds.

The preparation of plants for some parts of the border necessarily involves much thought and considerable additional labour, but this will be amply repaid by the increased charm and interest of the border. At Hampton Court some of the flowering trees and shrubs are grown in pots, and when coming into bloom are arranged in small groups with the pots plunged to the rim in the soil; and very beautiful is the effect they produce. Several of the liliums—notably, L. longiflorum—are also grown largely in pots, and arranged in bold groups. Specially-prepared early-flowering chrysanthemums are also extremely useful towards the end of the summer. Fortunately these can be grown in an open quarter in the reserve ground, and transferred to the border without receiving any considerable check, provided they are carefully handled and well watered in. G. G.

FULWELL PARK.

Lysons wrote that the neighbourhood of Twickenham had long been the favourite retreat of the scholar, the poet, and the statesman, and that nearly every house had "its tale to be told." Twickenham Park was once the home of Lord Chancellor Bacon, who considered it a fit residence for persons to study in. It is recorded that all the weeping willows in Britain originated from a tree which Mr. Vernon, a later owner, brought from the Euphrates and planted in Twickenham Park. But as other people imported trees the statement is not quite correct. Whitton Place, situate not far away, was more famous in arboriculture, for here Archibald, Duke of Argyle, made a noted collection of exotic trees. Many of these have gone the way of all trees, for only a small proportion of exotic conifers are long-lived in this country, and, like so many of the one-time famous demesnes of the neighbourhood, Whitton has passed under the auctioneer's hammer as a highly eligible building site.

FULWELL PARK, TWICKENHAM.
View from the windows of King Manoel's residence.

Considering the residence of Queen Amelie in the neighbouring royal borough of Richmond, and the associations of Twickenham, it is small wonder that King Manoel, when casting about for a home near London, fixed upon Fulwell Park, which, even though it does not possess any historic trees, is very pleasantly wooded. Here, on November 28, he brings his consort. For some time a small army of workmen have been busily engaged in the house, and due attention is to be paid to the garden for the purpose of making it beautiful. In the past, beds of roses and gorgeous summer flowers have been a feature of the Fulwell Park Gardens, and in the near future the favourite flowers of the Royal pair are to be planted extensively.

Cecil Aubrey.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

WINTER-FLOWERING CYPRIPEDIUMS are now at their best. The temperature of the house in which they are flowering should be rather lower that of late, and kept as even as possible. The moisture in the atmosphere should also be reduced, and especially is a drier atmosphere desirable towards evening when the lower temperature is reached. We have not now to consider only Cypripedium insigne and one or two others of the more robust kinds, for there are many of the newer kinds which are not so substantial in texture, and these are easily disfigured by damp when the atmosphere is heavily laden with moisture, and the cooler conditions outside cause a rapid fall of the temperature inside. It is also a good plan when cypripediums are required for house decoration, or exhibition, to see that the potting compost is reasonably dry before their removal. Plants rarely suffer from a few days' exposure in the house if treated thus, but when wet they suffer badly.

REPOTTING.—It is not desirable that plants of any description should be disturbed at the roots until the New Year, but where there are so many items calling for attention at a later period it is often necessary to pot any plants needing attention as soon as they have passed out of flower. Many will be found to be rooting now, and care must be taken that little injury is caused in turning out the plants and removing the old potting compost. I have on several occasions pointed out that the conditions under which cypripediums are grown has a considerable bearing upon the kind of compost they grow best in. In the immediate neighbourhood of London and other smoky districts, where the light is so poor during winter, it is generally found that very little, if any, loam should be used in the potting compost, for the reason that loam retains moisture over a long period, and the roots suffer considerably. In brighter and more favourable surroundings most of the green-leaved section of winter-flowering cypripediums may be grown successfully in nothing else but fibrous loam, with sufficient sand, charcoal, and broken crocks to render it porous, and with ample drainage below. The pots should be filled to about one-third their depth with drainage material, and whatever potting compost is considered most suitable; it should be made firm about the roots.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREEN-HOUSE.

CHRYSANTHEMUMS.—The main batch will now be passing out of flower, and the grower must make preparations for another season. Before propagation is commenced it will be wise to make a careful survey of the old stock with a view of discarding inferior kinds. There are so many really good varieties now in existence that it is folly to grow those which are poor from a decorative point of view. The single varieties undoubtedly find the most favour, and as these may be had both early and late, and there is such a diversity of beautiful colours among them, the bulk of the stock for conservatory decoration should consist of this section. As the plants pass out of flower they should be cut down and cleaned and placed in a cool, light structure as near the glass as possible.

PROPAGATION.—This may commence at once, provided suitable cuttings are available. The soil should be prepared, and allowed to remain on the potting shed bench for a few days before propagating commences. A suitable compost consists of loam, leaf-soil, and coarse sand. There is no better place in which to strike the cuttings than a box-frame erected on the stage in a greenhouse, as near to the light as possible. It is often the case that some of the choicest varieties are very shy in giving cuttings, and these should be placed in a warmer house—such, for instance, as a vinery or peach house, which has just been started.

CINERARIAS.—The earliest cinerarias are now throwing up their flowers, and, if necessary, they may be encouraged to flower a little earlier by placing them in a slightly warmer house. Plants in cold frames should be brought indoors now, as they are easily damaged by frost. They will need plenty of water, and stimulants may be given more frequently, and with increased strength. Lightly fumigate the house occasionally to destroy aphis, and keep a sharp look-out for the leaf-mining maggot.

FORCED SHRUBS.—A few shrubs suitable for forcing may now be potted up and placed in heat. Lilacs are among the most useful, and if a batch is grown in the open ground they may be forced successfully every second year. Lift the plants with a good ball of roots attached, and pot them, using ordinary garden soil. Ghent and mollis azaleas, prunuses, staphyleas, viburnums, etc., may all be forced now. A few plants of Azalea Deutsche Perle should also be placed in heat.

LILY OF THE VALLEY.—Until the turn of the year it will be wise to rely upon retarded crowns for a supply of lily of the valley. Afterwards clumps from outdoors may be forced. Where a large supply of flowers is required for cutting, well-established crowns may be dug from outdoors and placed over a moderately warm hotbed in a heated frame. Cover the roots with soil and water them with tepid water. Keep the frame covered with mats until the spikes are 4 or 5 inches high, then gradually expose them to light.—E. Harriss, Lockinge Gardens.

HARDY FRUITS.

PEARS.—These may be pruned in favourable weather at any time from now until March. When dealing with bush trees, keep the heads fairly thin, as nothing is more harmful that overcrowding with useless wood. All the main leaders will need to be shortened more or less; in the case of full-sized bushes they should be shortened to within a few buds of the last year's wood, and side shoots to within a couple of good buds. In the case of young trees, allow the fresh growths to remain 12 or 15 inches in length, cutting just above a bud pointing in the direction the next growth is required. When pruning, do not forget, if grafts are required, to take care of as many growths as are needed, keeping them true to name, and heeling them in on a north border until required.

ESPALIERS.—Remove a few of the old spurs each year along the main tiers, and thus encourage plenty of healthy fruit buds close to the main wood. Inferior varieties, if the trees are healthy, should be grafted in spring with more suitable kinds. In the case of good varieties, if the trees are somewhat old and the branches clothed with old and useless snags, they can be greatly improved by cutting away the branches near the main stems and training fresh shoots in their place. It is marvellous how well the new wood grows and produces large fruits for many years.

MORELLA CHERRIES.—We have finished the nailing and training of Morella cherries, as I like to get the work done before the cold weather sets in. Only young trees have been taken entirely from the walls. Older ones which were thoroughly overhauled last autumn needed very little fresh training, but have been carefully examined. The young shoots are kept straight and trained all over the trees, both for supplying good fruits and for filling up any gaps that may occur. A good dressing of lime will be applied over the roots of these trees, with the addition of loam and bone-meal. When dealing with young, newly-planted trees, allow plenty of time for the settling of the soil before finally securing them to the walls, then select suitable shoots and train them straight from the stem in the different directions to form an evenly-balanced head, shortening them more or less as required. When once the framework is properly set there should be very little further trouble in maintaining good, fruitful trees.

STRAWBERRY BEDS.—Most of our old beds have been well mulched, and the younger stock will be by this date. I know some gardeners do not recommend early mulching, but much depends on the nature of the soil and the situation in which the strawberries are planted. Should very severe weather set in, mulching may prove valuable.—H. Markham, Wrotham Park Gardens.

THE KITCHEN GARDEN.

DIGGING AND TRENCHING.—Advantage should be taken of every favourable opportunity to prepare the soil for next season's crops; if this matter is left over until late in the season, the presence of other work often causes it to be done in a hurry, to the detriment of future crops, and disappointment of the cultivator. It is advisable to carefully plan out the positions to be occupied by the various kinds of vegetables during the forthcoming season, and deal with each plot so as to meet the requirements of its prospective occupants. By following this method, confusion and much unnecessary labour and trouble will be avoided. A few instances may be noted. Carrots, parsnips, and beet do best on land that has not been freshly manured, and usually these root crops follow celery. Plots prepared for early potatoes should have very little strong manure, or the haulm will be unduly large, and the tubers proportionately small. The onion crop is an important one, and should have liberal treatment in the way of manure and deeply tilled soil. The position assigned to cauliflowers should be well manured, and either double-dug or bastard-trenched, particularly so if previously occupied by any of the Brassica family. Light and porous soils may be treated without difficulty unless there be snow or frost. On the other hand, heavy soils require careful treatment, and, if possible, should be dug or trenched when reasonably dry—at all times leaving the surface in a rough condition. It is a good plan to throw the soil into ridges, running from north to south, so as not to have a wet side and a dry one; a liberal addition of road scrapings, well-rotted garden refuse, and ashes from the rubbish fire, will materially help to make the soil more friable.

TURNIPS.—If roots of the later sowings have reached normal size, they should be lifted and laid closely together in trenches, covering them with soil; some strawy litter or bracken placed over them will facilitate lifting if severe weather sets in.

PARSNIPS AND JERUSALEM ARTICHOKES.—These are best left in the ground and lifted as required, but it is often advisable to take up and store away sufficient for two or three weeks' demand during mid-winter; this means a saving of labour should the ground be frostbound.

LETTUCE AND ENDIVE.—Vacant spaces in frames and pits should be filled up with outside-grown plants. They must be kept perfectly free from decaying leaves, and have the soil lightly stirred between them; admit air daily, the lights being removed in dry, bright weather. Seeds may be sown thickly in boxes once a fortnight to provide material for cutting in the young state.—W. Messenger, Woolverstone Park Gardens.

☛ *EVERY PRACTICAL GROWER AND GARDENER USES*

THOMSON'S VINE, PLANT AND VEGETABLE . . . MANURE—WHY?

Because our Manures are built up after many years of experience in gardening in all its branches. **We not only make and sell our Manures,** but **SHOW what can be done with them in our own establishment.** We have received Medals and Special Awards too numerous to mention for the finest produce—indeed, our **grapes are world-famous.** In greater demand than ever, after some 30 years on the market. Unrivalled at the present day for every description of Fruit Bearing, Flowering and Foliage Plants, Vegetables, Lawns, etc. Indispensable in every garden.

ALSO THOMSON'S SPECIAL TOP-DRESSING MANURE.

Prices :

Vine, Plant and Vegetable Manure.—1 cwt., **20s.**; ½ cwt., **10s.**; ¼ cwt., **6s.**; 14 lbs, **3s. 6d.**; 7 lbs., **2s. 6d.**; Tins, **2s. 6d., 1s.** and **6d.** Carriage paid on 1 cwt. anywhere.

Special Top-dressing Manure.—½ cwt., **20s.**; ¼ cwt., **11s.**; 14 lbs., **6s.**; 7 lbs., **3s. 6d.**; Tins, **1s.** Carriage paid on ½ cwt. anywhere.

Also Thomson's Book on the Vine, 11th Edition, 5s. post free. **THOMSON'S STYPTIC, 3s. and 1s. 6d. per bottle.**

Sold by Nurserymen and Seedsmen everywhere. Write for Pamphlets, Price Lists, etc., to Sole Makers.

A Reputation for supplying the very finest fruit trees is one of our chief assets, and we are living up to it.

No order is too small to receive our best attention, none is too large for our organization.

Let us quote for your next order. We can assure you that we will justify our request.

We will gladly send a copy of our catalogue upon hearing from you.

H. CANNELL & SONS,
Fruit Lands, EYNSFORD KENT.

TWO
Indispensable Good Things.

(1.) OUR PATENT SPRING CALYX BAND, which is a guarantee against split Carnation Pods. (Samples free on application.)

(2) OUR CATALOGUE DE LUXE, a splendid edition, entirely devoted to **Border and Perpetual Carnations and Roses,** containing magnificent natural colour photographs of the newest varieties and exhaustive articles on culture. Price **6d.** (refunded on first order, minimum 5s.)

EXHIBITIONS AND MEETINGS.

Newcastle.

The ninth annual exhibition was held in the Concert Hall and Corn Exchange, Town Hall, Newcastle, on November 19 and 20. The entries were more numerous than usual and the general quality of the exhibits superior to that of any previous year. It is also satisfactory to record that the attendance was large, and should assure a financial success. The Hon. Lady Parsons opend the show on the first day.

CUT FLOWERS.

For a dozen vases of Japanese blooms, not less than twelve varieties, three blooms in a vase, a silver cup, value £5 5s, and £5, was offered as first prize, and this was won by Mr. H. Smith, gardener to R. D. Marshall, Esq., Castlerigg Island, Keswick, with a grand lot of blooms, comprising Mrs. F. N. Vallis, Frank Payne, Reginald Vallis, Lady Conyers, W. Rawlings, F. T. Mew, W. Turner, Master James, Lady Talbot, Mrs. G. Drabble, Queenie Chandler, Frances Jolliffe, F. Rowe, and Sir F. Crisp; Mr. R. Addison, gardener to the Countess of Ravensworth, Cresswell Hall, Morpeth, second, with fine blooms of F. Rowe, Lady Talbot, Algernon Davis, Edith Jameson, Eclipse, Frances Joliffe, and Mrs. G. Mileham; Mr. J. Kerr, gardener to Dr. J. B. Simpson, Bradley Hall, Wylam, second; Mr. C. L. Cawkill, gardener to F. Straker, Esq., Angerton, Morpeth, third.

In the class for six vases of Japanese blooms, not fewer than six varieties, there was a good competition, and the flowers generally were of good quality. Mr. H. Smith led again with William Turner, William Rawlings, Algernon Davis, Hon. Mrs. Lopes, Mary Poulton, Kara Dow, Lady F. Ryder, Sir F. Crisp, and Mrs. Drabble; Mr. J. Askew, gardener to the Right Hon. W. Runciman, Esq., M.P., Doxford Hall, Chathill, second his blooms of Mrs. A. T. Miller and Pockett's Crimson being very fine; Mr. A. W. Appleton, gardener to C. Lacy Thompson, Esq., Brampton, third.

For four vases of Japanese blooms, four varieties, Mr. H. Smith was again first, W. Turner and Lady Talbot being particularly fine in his set; Mr. A. W. Appleton second, with larger blooms, which were past their best; Mr. T. Swan, gardener to Major Innes Hopkins, third. For three Japanese blooms (white), Mr. Smith led with White Queen; Mr. J. Thomas, gardener to the Right Hon. Viscount Allendale, Bywall Hall, Stocksfield, second, with W. Turner; and Mr. Appleton third with Purity. For three Japanese blooms (yellow), Mr. Appleton led with F. S. Vallis; Mr. T. Eldin, gardener to F. R. A. Sheel, Esq., Leazes Hall, Burnopfield, second. For three Japanese blooms, any other variety, Mr. R .Addison was first with F. Grun; and Mr. Elsdon second with George Hemming.

Mr. J. Askew led for four vases of incurved blooms with Ethel Thorp, Clara Wells, Buttercup, and Mrs. G. Denyer; Mr. J. Thomas, second. For two vases of incurved blooms, Mr. Askew was first, and Mr. Dodds, Sandeford Park, Newcastle, second. For six vases of single chrysanthemums, Mr. Thomas was first, Sylvia Slade, Florrie King, and Mrs. Pulling being very fine in his stand; Mr. J. Kerr second; and Mr. C. L. Cawkell third.

In the classes confined to Northumberland and Durham, Mr. J. Askew was first for four vases of Japanese blooms with Mrs. A. T. Miller, Frances Jolliffe, Mrs. W. Blackwood, and Lady Talbot; Mr. Thomas second, F. S. Vallis being the finest in his set; Mr. Jas. Kerr third. In the local class, confined to within three miles of Newcastle, Mr. J. Hale, gardener to Mrs. Hunter, The Grange, Wickham, led; Mr. J. E. Fairlie, gardener to W. Higginbottom, Esq., coming second. For two vases, Japanese, Mr. J. Henderson, gardener to the Right Hon. Sir E. Grey, Bart., K.G., M.P., Fallodon Hall, Lesbury, was first, his J. H. Silsbury and F. S. Vallis being very fine blooms.

GROUPS AND PLANTS.

For a group of chrysanthemums, arranged with other foliage and foliage plants on a space 10ft. by 6ft., Mr. H. Hillier, Green Park, Darlington, was first. His chrysanthemums were very fine, grouped with foliage plants, orchids, and cyclamen, and the whole was very effectively displayed. Mr. T. Bell, gardener to A. E. Bambridge, Esq., Lynwood, Jesmond, was a close second; Mr. J. Hetherington, gardener to C. T. Kendell, Esq., North Shields, third; and Messrs. Carnegie and Co., fourth.

The best table of single chrysanthemums, 5ft. by 3ft., arranged for effect, was from Mr. W. Lambert, gardener to Earl Grey, Howick Hall; Mr. Cawkell second, and Mr. T. Swan third.

The bush plants, both in the open and local classes, were a feature of the show, nearly one-half of the centre of the Corn Exchange being filled with well-grown specimens from leading prizewinners already named.

The ten-guinea challenge cup for the best floral table decoration was won by Mr. J. Kerr, who used winter-flowering begonias, croton foliage, etc.; Mr. Lovett, Lilburn Towers, second, and Mr. W. H. Lambert third.

FRUIT AND VEGETABLES.

In the fruit classes, for two bunches of white grapes, Mr. R. Elliott, Binton, was first with Muscat of Alexandria; Mr. T. Bell, Jesmond, second. For two bunches of black grapes, Mr. J. Hetherington led; Mr. Thos. Elsdon was second; and Mr. A. Paxton, Ryton, third. For the best six dishes of dessert apples, Mr. H. G. Lloyd, gardener to Dr. Stewart, Hischam, came first, his Charles Ross and James Grieve being very fine; Mr. D. Mackie, gardener to Mrs. Bambridge, Felton, second. Dr. Stewart was also first for culinary apples.

For twelve dishes of outdoor-grown apples Mr. Lloyd was first, his Newton Wonder, Bismarck, and Peasgood's Nonsuch being particularly fine; Mr. Jas. Hale, Hexham, second.

Mr. T. H. Bolton, gardener to the Earl of Devon, Powderham Castle, Devon, sent an honorary exhibit of thirty-six dishes of apples, which was awarded the North of England Horticultural Society's plaque.

The vegetable classes were well filled, and for a collection of ten kinds, Mr. R. Shield, Swalwell, was first; Mr. W. Telford, West Wylam, second; Mr. J. Forrester, Whitby Bay, third.

In the leek classes the local colliers were very keen; the three leeks shown by Mr. G. Robly, Fourstones, contain edible blanched stem, amounting to 182.2 cubic inches; Mr. Thomas, Bywell Gardens, second. For three heads of white celery, and also for three heads of red celery, Mr. W. Telford was first.

There was a keen competition in all the vegetable classes, and the new class for six dishes of potatoes brought out a large entry, Mr. J. Kerr coming first; Mr. A. Cowe, Kelso, second; and Mr. Askew third.

TRADE DISPLAYS.

Gold medals were awarded to Messrs. Finnys, Granger Street, Newcastle, for a fine display of forced lily of the valley, winter-flowering begonias, floral designs, and sundries; to Mr. W. Lawrenson, Yarm and Newcastle, for conifers, heaths, cyclamens, and other flowering and foliage plants; to Messrs. Kent and Brydon, Darlington, for a collection of hardy fruits, spiræas, liliums in variety, etc.; and to Messrs. Michie and Co., Alnwick, for a fine collection of apples.

Silver-gilt medals were awarded to Messrs. W. J. Watson, the Tyneside Seed Stores, Newcastle; Messrs. Cooper and Nephews, Berkhampstead; and to Messrs. Stuart and Mein, Kelso.

Eccles Horticultural Society.

NOVEMBER 7 and 8.

The annual show of this society was held at the Town Hall, and the number of exhibits was in excess of former years. As a result the committee were compelled not only to refuse trade exhibits, but a restriction had to be placed on the entries in the competitive classes.

For the half-circular group of chrysanthemums there were six entries, the leading ones being admirably arranged with bright, fresh blooms, generally a mixture of Japanese and singles. The leading awards were made in favour of Mr. H. Palethorpe, gardener to Miss G. Agnew; Mr. E. Pollitt, gardener to J. Smylie, Esq.; and Mr. W. D. Wilson, gardener to Miss A. M. Phillips. For three plants of Japanese, Mr. W. Balson, gardener to James Brown, Esq., led with well-flowered examples; this exhibitor also obtained premier honours for three specimens of incurved varieties. In the class for three singles, Mr. W. Holmes, gardener to W. S. Forbes, Esq., was successful in taking the first place; and for three plants not disbudded, Mr. A. E. Fox, gardener to T. C. Ansdell, Esq., proved successful, as also in the class for the six plants of decorative kinds. Mr. E. W. Dew was successful in securing the Mayor's silver challenge cup for three specimens of single varieties.

Mr. W. Foster had the leading table plants, Mr. D. Sweeney staged the best Roman hyacinths, and Mr. A. E. Fox was first for Begonia Gloire de Lorraine.

The section devoted to cut flowers showed a marked improvement throughout. The prizes for twenty-four blooms, twelve Japanese and twelve incurved blooms, brought three excellent entries, in which Mr. C. Goves, gardener to Sir Gilbert Greenall, Bart., maintained his last year's position by winning with a grand set. Especially fine were the blooms of F. S. Vallis, W. Turner, and Lady Talbot among the Japanese; and the most noteworthy incurved were Godfrey's Eclipse, Lady Isabel, Clara Wells, Mrs. G. Denyer, and Yellow Hygate. Mr. J. Stoney, gardener to Lieut.-Colonel Gaskill, was second; and Mr. J. George, gardener to Thomas Henshaw, Esq., third. In the class for twenty-four Japanese, not less than twelve varieties, the awards were made in favour of Mr. C. Goves, who was again in strong force; Mr. J. Copper, gardener to H. Belk, Esq.; and Mr. J. Stoney. For twelve incurved, twelve Japanese, and for twelve consisting of equal numbers of incurved and Japanese, Mr. Goves was first; and in each class Mr. J. Stoney was second.

Bouquets were excellent, and for three Mr. A. Porter scored, utilising with much taste choice orchids. This exhibitor was also first for a bouquet of chrysanthemums and for a table epergne. In the class for baskets of chrysanthemums, Mr. J. Roberts, gardener to Miss A. M. Lightbourne, was successful with a pleasing arrangement; Mr. J. Copper had the best sprays; and Mr. J. M. Hodson the first prize button-holes.

In the section open to exhibitors resident within eight miles of the Town Hall, Mr. W. Balson was first for the best dozen Japanese; Mr. J. Roberts obtained premier honours for the same number of incurved. Mr. W. Holmes was successful in the three classes for twelve blooms comprising six Japanese and six incurved. Mr. J. Ridgway occupied the first place for six vases of Japanese varieties, distinct, three blooms in each. Mr. G. W.

Byrom, gardener to Lord Brackley, was successful in securing the handsome challenge vase presented by T. C. Ansdell, Esq., staging finely developed blooms. Mr. A. E. Fox proved the winner for six vases single chrysanthemums.

Mr. W. Elkin contributed some fine specimen palms not for competition. The arrangements were ably carried out by Mr. W. Elkin, chairman, Mr. F. Blower, secretary, and the committee.

Norwich.

On November 20, 21, and 22 the Norfolk and Norwich Horticultural Society held its annual show of chrysanthemums, fruit, and vegetables in St. Andrew's Hall, and it was a remarkably fine show in every respect. Norwich had a great show week, and, simultaneously, the fat stock show, a poultry show, and a bull dog show were being held. But despite these counter attractions in the city there was a capital attendance at the chrysanthemum show, and everybody seemed well pleased with what they saw. There are still a good many growers of large chrysanthemums in Norfolk, and they support the society well, and the fruit and vegetable exhibits were probably the largest and best the society has yet had. Entries were nearly a hundred in advance of last year, and the whole show bore witness to the fact that horticulture in Norfolk is progressing.

PLANTS.

A circular group of chrysanthemums and foliage plants formed the opening class in the schedule, with three entries. A challenge cup, accompanied by 60s. cash, went to the winner, Mr. T. Notley, gardener to E. G. Buxton, Esq., Catton Park, Norwich. The group was attractively arranged, and, in spite of the orthodox circular form, there was a touch of originality that we admired. There were no big specimens, but all were of useful size, the well-grown plants carrying a number of moderately sized flowers. A few good singles were used, and the colours ranged from pure white through yellows and bronzes to deep crimson. Variegated abutilons were freely used, but a novel idea was the introduction of young grape vines showing all the rich tints of their autumn foliage. Second prize was secured by Mr. A. Bentley, gardener to the executors of Sir R. Beauchamp, Bart., Langley Park. In this group there were a number of specimen blooms of Japanese varieties, together with small-flowered singles; aspidistras and Dracæna australis were the principal foliage plants, and there was evidence of taste in the blending of colours as well as the design of the group. Mr. D. Cockerill, gardener to G. E. White, Esq., Eaton House, Norwich, was placed third.

BIG BLOOMS ON BOARDS.

The Norwich Society has not altogether discarded the show boards for big Japanese and incurved flowers, and there is still a good deal of enthusiasm among the exhibitors, and the classes for forty-eight, thirty-six, and twelve blooms make a great show. Mr. H. E. Strudwick, gardener to Sir S. Neumann, Bart., Raynham Hall, Norfolk, was the winner of the Lord Mayor's prize for forty-eight blooms. His stand was remarkable for uniformity and even quality. It was not a question of pointing to a bloom or two as the best, but rather of saying all were good; Mrs. G. Drabble and Wm. Turner were the chief whites, and an unnamed seedling yellow was rich in colour and of good form. Mr. E. Leach, gardener to W. H. Palmer, Esq., Ormesby, secured second prize, and in this case there were some particularly fine blooms, but others were somewhat weak. Mrs. G. C. Kelly was splendidly shown, H. E. Converse and Mrs. W. Iggulden also being good. The lead for thirty-six blooms was taken by Mr. A. Bentley, Langley Park. He was strongest in the darker reds and crimsons, such varieties as His Majesty, T. Chandler, and Reg. Vallis being among the best; Mr. Chas. Nichols, gardener to T. A. Rising, Esq., Manor House, Ormesby, took second prize, his leading varieties being Mrs. G. Drabble, F. S. Vallis, D. B. Crane, and W. Rawlings. Mr. Joshua King, gardener to Geo. J. Hacker, Esq., Great Ormesby, was placed third, there being four entries in the class.

J. F. Gaymer, Esq., Millfield Cottage, North Walsham, was first for twelve blooms, Japanese, and some of his flowers were very fine; Splendour, D. B. Crane, Marie Loomes, and F. S. Vallis deserve special mention. Second prize in this class went to Mr. R. Nicholls, gardener to Sir G. Lacon, Bart., Ormesby Hall; Mr. A. Gipson, gardener to Sir Edward Mann, Bart., Thelveton Hall, being awarded third prize. In a strongly contested class for six blooms of any one yellow variety, Mr. H. E. Strudwick's half-dozen of F. S. Vallis stood right away from the rest, and they were magnificent blooms; second prize went to Mr. A. Bentley, Langley Park, his variety being Willie Rawlings. The best six whites were Mr. J. F. Gaymer's set of W. Turner, beautiful, compact, and rich-looking blooms.

Mr. T. J. Broom, gardener to Miss Langworthy, Gays House, Holyport, Berks, secured the leading award for incurved varieties with a dozen shapely, reasonably large flowers that showed expert culture; Mr. W. Chettleburgh, gardener to Colonel Rous, Worstead House, Norwich, received second prize, but his Ethel Thorpe were large and coarse. Mr. Bentley, Langley Park, had the best half-dozen incurved varieties; and Mr. Broom scored with six of one variety, showing Chas. Pacque.

VASE CLASSES.

A fine effect was produced by a class for a display of cut chrysanthemum blooms on four feet run of tabling. Mr. Chas. Nichols, Manor House, Ormesby, was the successful exhibitor, showing some beautiful blooms, and just sufficient foliage to show them off well. Mr. R. Nicholls, Ormesby Hall, was the winner of second prize, and while we liked his blooms we did not admire their arrangement; Mr. A. Bentley was placed third. Five entries were staged. Twelve vases of naturally-grown chrysanthemums brought forward three entries, but it seemed a pity they should be so crowded on a small table as to practically destroy their decorative value. It should have been a pretty class, but was simply a jumble. Mr. M. Evans, gardener to Mrs. W. R. Mills, Brooke House, near Norwich, took the lead, showing some good serviceable flowers; second prize went to the credit of Mr. E. F. Greene, gardener to Edmund Reeve, Esq., The Grange, Old Catton. Mr. M. Evans was again successful with six bunches of single chrysanthemums in a well-filled class.

MISCELLANEOUS CUT FLOWERS.

There was a class for a group of cut carnations, and here the first prize winner was Mr. Wm. Allen, Gunton Park, Norwich; Enchantress, Carola, Lady Alington, and Mary Allwood figured among the varieties used. Mr. J. D. Cockerill, Eaton House, secured second award.

A touch of variety was supplied by a class for twelve bunches of miscellaneous stove and greenhouse flowers; Mr. H. Rogers, gardener to Lord Rendlesham, Rendlesham Hall, was awarded first prize, and he had poinsettias in grand form, and some good zonal pelargoniums, cypripediums, and other orchids. Second prize was awarded to Mr. J. Hilsoe, gardener to Sir Fredk. Adair, Bart., Flixton Hall, Norfolk, who had some very choice and somewhat uncommon flowers; Isoloma hirsuta, Plumbago rosea, Browallia speciosa major, and Calanthe vestita rubra were a few of the best subjects in a set that must have run the winner closely.

Chief among the miscellaneous plants were some beautiful examples of Begonia Gloire de Lorraine, and Mr. T. Notley was awarded first prize for three fine specimens; Mr. E. F. Greene's second prize lot were a little larger, but not so evenly flowered; Mr. R. Woodhouse, Old Catton, was third. Mr. E. F. Greene was foremost with three plants of Begonia Turnford Hall, Mr. R. Woodhouse securing second prize. Cyclamen, primulas, salvias, and other pot plants were not particularly strong features.

FRUIT.

A separate hall of great size was set apart for the large quantities of fine fruit. A challenge bowl was offered for a collection of twelve dishes of dessert fruits, and Mr. Wm. Allen was the recipient of this coveted award. His Muscat of Alexandria grapes were of good colour, but just beginning to show signs of shrivelling; Gros Colmar were superb, and Mr. Allen also had splendid Ribston and Cox's Orange Pippins, and Beurre Alexandre Lucas and Marie Louise Pears. Second prize was secured by Mr. J. Hilson, Flixton Hall, who was strong with Peasgood's Nonsuch apples and Charles Ernest pears, but lost points on grapes. Mr. Wm. Chettleburgh, Worsted House, won third prize. Mr. Allen took the lead for three bunches of black grapes, showing Alicante, very well finished and of good size; and he repeated his success in another class for three distinct varieties of black grapes, showing Gros Colmar, Melton Constable, and Alicante. Mr. Allen's three bunches of Muscat of Alexandria took the leading award, and the same exhibitor won in the single bunch class.

Ten varieties of dessert apples, outdoor growth, made a good class, and Mr. Wm. Allen scored with Allington Pippin (of good size and bright colour), Charles Ross, Cox's Orange Pippin, Gascoyne's Scarlet, Rival, Mabbot's Pearmain, Ribston Pippin, Blenheim Orange, and King of the Pippins, King of Tomkin's County completing the set. Mr. J. Hilson received second prize for fruits of good quality and colour; the third prize winner was Mr. Wm. Chettlenburgh. For the smaller collection of dessert fruits there were six entries, six dishes being the number staged by each competitor; Mr. H. S. Strudwick, gardener to Sir S. Neumann, Bart., Raynham Hall, was the winner of the first prize, a dish of American Mother included in his set being very fine in colour; second prize was secured by Mr. F. J. Endersby, gardener to J. H. Gurney, Esq., Keswick Hall; and third prize by Mr. T. Jones, gardener to E. G. Cubitt, Esq., Honing Hall, Norfolk.

Mr. Jones claimed the highest place for nine dishes of culinary apples with some grand examples of Peasgood's Nonsuch, The Queen, Lord Derby, Bramley's Seedling, Warner's King, Lane's Prince Albert, and other excellent varieties; Mr. G. D. Davison, gardener to Colonel B. J. Petre, Westwick, Norwich, was second in this class, and it was very difficult to detect any point wherein the apples in his exhibit were inferior to those of the first prize lot.

First prize for six dishes of culinary apples was won by Mr. J. Hilson, who was followed by Mr. H. Wolterton and Mr. E. H. Starling. For a collection of six varieties of dessert pears, Mr. Davison won first prize, and the R.H.S. Affiliated Societies' Silver-gilt Medal; Durondeau, Marie Louise, Doyenne du Comice, Emile d'Heyst, Beurre d'Avalon, and Pitmaston Duchess were the varieties staged; Mr. W. Allen, Gunton Park, was awarded second prize.

VEGETABLES.

These were a very strong section, and, although accommodated in the vaults beneath the hall, they were of sufficient interest to attract most of the visitors, not excepting the ladies.

A class for a collection of twelve dishes brought eight entries, and some of the produce shown was splendid. Premier award and silver medal was won by Mr. E. A. Starling, gardener to the Right Hon. Sir A. E. Fellowes, K.C.V.O., Honingham Hall. His Ailsa Craig onions were weighty and shapely, while leeks were of capital size and quality, as also were Intermediate carrots, Tender and True turnips, Blood Red beet, and Duchess of Cornwall potatoes; Mr. T. J. Broom, Holyport, Berks, ran the winner very close, and secured second prize; Kohl Rabi, mushrooms, French beans, and

BIRMINGHAM CHRYSANTHEMUM SHOW FOR 1914
Will be held at BINGLEY HALL,
10th, 11th, and 12th, November.
ALFRED NOAKES, Secretary.
148, Bristol Street, Birmingham.

PERPETUAL-FLOWERING CARNATION SOCIETY.

THE 15th EXHIBITION
will be held at
THE ROYAL HORTICULTURAL HALL,
WESTMINSTER,
on WEDNESDAY, December 3rd, 1913.
Open 12 noon to 5 p.m. Admission, 1s.
Schedules and other particulars from the Hon. Secretary,
T. A. WESTON, Floradale, Orpington.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

artichokes were included in this exhibit. Mr. Edgar Chambers, gardener to Captain H. H. Francis, Long Stratton, received third prize.

Potatoes were very largely shown, there being a long list of classes, several of which were for six dishes of six tubers each. The names of Mr. Edgar Chambers, Mr. A. Woodhouse, Mr. F. Wilby, and Mr. E. Dix figured prominently among the winners of first prizes. Onions, parsnips, celery, and all other seasonable vegetables had classes to themselves, which were well filled.

NON-COMPETITIVE.

Messrs. Sutton and Sons, Reading, put up an extensive and pleasing exhibit of choice vegetables decorated with single chrysanthemums. Gourds of various forms and colours were used, and the whole exhibit bore the stamp of high quality. Messrs. Daniels Bros., Lim., Norwich, filled a large space with exhibits of single chrysanthemums, poinsettias, liliums, and other flowers, and a table of fruit; the firm also showed bouquets and other examples of floral art.

An extensive and fine exhibit was made by Messrs. Hobbies, Lim., Norfolk Nurseries, Dereham; single-flowered chrysanthemums, disbudded, and of considerable size, were shown in mounds. Merstham Jewel, bronze; J. B. Lowe, brilliant crimson; Silvia Slade, maroon; and Sandown Radiance, scarlet, were among the most noticeable. There were a few collarette dahlias, and some good blooms of Lilium nepalense on this stand, which occupied half one side of the hall. A group of carnations from Messrs. Stuart Low and Co., Bush Hill Park, Middlesex, included Sunstar, Gorgeous, Carola, and other popular varieties arranged with good taste.

In front of the band-stand Mr. G. W. Miller, Clarkson's Nurseries, Wisbech, exhibited a collection of orchids, prettily arranged, the tricolor form of Saxifraga sarmentosa making a nice edging to the group. Messrs. Pipers, Bayswater, London, had a stand of decorative chrysanthemums, among which Golden King, A. J. Balfour, Hortus, and other cheerful varieties were prominent. A small group of fine big blooms from Messrs. W. Wells and Co., Lim., Merstham, included superb flowers of Mrs. Gilbert Drabble, Queen Mary, H. E. Converse, and, of course, Daily Mail.

Messrs. W. Seabrook and Sons, Chelmsford, staged a very good collection of apples arranged in flat baskets; many varieties carried bright colour, and some were of immense size, while all were of high quality. Mr. Thomas Ward, The Graperies, Bishop Stortford, exhibited cut chrysanthemums of good market value. Messrs. Clibrans, Altrincham, made a feature of single-flowered chrysanthemums, among which one named Mrs. J. S. Crawford appealed strongly to us by the distinct formation of its petals, which flattened out at the ends and made a very attractive flower. Their bank of bright, freely-flowered begonias was a very attractive feature of the show.

MEDAL AWARDS.

Gold.—Messrs. Sutton and Sons, Reading; Messrs. Daniels Bros., Lim., Norwich.

Silver. — Messrs. Seabrook and Sons, Chelmsford; Mr. G. W. Miller, Wisbech; Messrs. Clibran, Altrincham; Messrs. Hobbies, Lim., Dereham; Messrs. W. Wells and Co., Lim., Merstham; Messrs. Stuart Low and Co., Bush Hill Park; and Mr. Thos. Ward, Bishop Stortford.

Hull Chrysanthemum Society.

NOVEMBER 19 and 20.

Thirty years have elapsed since this society held its first exhibition, and it is therefore a matter of much interest that we are able to record the fact that the show which was held in the City Hall on the 19th and 20th inst. was the finest of the long series of magnificent displays that have brought fame to the town as a centre of chrysanthemum culture. Not only was the exhibition of great magnitude and surpassing beauty, but the interest evinced in it by the townspeople was so great that the large hall was well filled within a quarter of an hour or so of the doors being opened at noon. By half-past twelve o'clock, when the Mayor of Hull, with the members of the Corporation, ascended the platform to take part in the opening proceedings, the building was packed, and abundant evidence was forthcoming that the visitors were in full sympathy with the society and its work. It was interesting also to find that a large proportion of those who assisted in establishing the society are still actively engaged in its management, these including Mr. Dixon, one of the co-honorary secretaries. Unfortunately Mr. Dixon was unwell, and the whole of the secretarial duties fell upon Mr. E. Harland, who may be heartily congratulated on the success he achieved. The City Hall buildings comprise a magnificent hall, and several minor halls of various dimensions, and of these the first-named was devoted to cut blooms and groups arranged for effect, and the others were set apart for examples of the decorative art, fruits, vegetables, and non-competitive exhibits. The groups formed a distinct and highly effective feature, and cut blooms were staged in immense numbers and in splendid style, while fruits and vegetables were admirably represented.

CUT BLOOMS—OPEN CLASSES.

No finer blooms of any one of the sections have been shown this season than those which were staged at Hull, and the competition was so keen that to obtain a high position on the prize list was no light honour. The leading class in this section was that for twenty-four blooms of Japanese in eighteen varieties, and there were four entries—all more or less good. Mr. A. Chandler, gardener to Arthur James, Esq., Coton House, Rugby, was successful in obtaining premier honours, staging splendidly developed blooms of Lady Talbot, W. Mease, Queen Mary, T. Lunt, Purity, Valerie Greenham, Bob Pulling, Francis Rowe, Miss M. Fox, W. Turner, December Gold (a bold flower remarkable for its rich colouring), Fred Green, F. S. Vallis, Bessie Godfrey, His Majesty, and Mrs. G. Drabble; Mr. F. J. Fleming, gardener to S. M. Hewitt Weekley, Esq., Old Hall, Grimsby, came second.

Next in importance in the classes open to all was that for eighteen incurved, in not less than twelve varieties. The entries were numerous, and blooms highly meritorious. In this Mr. G. Wilson, gardener to Mrs. Eyre, Bishop's Burton Hall, Beverley, occupied the first place with flowers comparatively large in size, even in outline, and finely finished. Of exceptional merit were the varieties of F. Palmer, G. F. Evans, W. Pascoe, Godfrey's Eclipse, Lady Isobel, Calypso, Buttercup, Duchess of Fife, L. Peyron, and Eva Smith. Mr. G. W. Musk, gardener to Captain J. F. Laycock, Wiseton Bawtry, followed closely for second place; and Mr. A. Chandler was third with an excellent stand.

The classes for blooms shown in vases were remarkably well filled, and the flowers were superbly developed. For two vases of white Japanese, seven blooms in each, Mr. G. W. Musk was first, and Mr. A. Chandler second, with magnificent examples of Mrs. G. Drabble and W. Turner; Mr. F. J. Fleming, who was third, also had finely developed specimens. In the corresponding class for yellow Japaneses there were fifteen competitors, and not an indifferent vase among the thirty staged. Mr. A. Chandler obtained premier honours with F. S. Vallis and Lady Talbot in grand form, and was closely followed by Mr. G. W. Musk and Mr. G. Wilson for second and third places. The awards for six blooms of any one Japanese variety were made in favour of Mr. A. Chandler, Mr. F. J. Fleming, and Mr. G. W. Musk, the first prize six being Lady Talbot; and W. Mease was shown by the second and third prize winners.

Decorative and single varieties in vases were so largely shown as to constitute a distinct and attractive feature. With so large and interesting a display of these varieties it was unfortunate that so many exhibitors should have considered it unnecessary to name their flowers. Fifteen entered into competition for the prizes for twelve vases of single chrysanthemums in not less than nine varieties, three stems of one variety in each vase. The flowers were closely matched in point of merit, and the premier award was made in favour of Mr. G. Bennett, gardener to Mrs. Nightingale, Cliffdene, Bridlington; Mr. M. Stather, Arlington Nursery, Cottingham; and Mr. W. R. Tranmer, Alma Nursery, Cottingham, following. There were nine competitors in the class for six vases of single varieties, disbudded to one bloom on a stem, and five blooms of one variety to be shown in each vase. The successful competitors were Mr. M. Stather, Mr. W. R. Tranmer, and Mr. A. Drewery, gardener to H. Hildyard, Esq., Cherrygarth, Cottingham. The class for six vases of decorative varieties, disbudded to one flower on a stem, contained six entries, all possessing much merit, and the prizes were awarded to Mr. W. R. Tranmer, Mr. A. Drewery, and Mr. H. Taylor, Preston, Hull.

CUT BLOOMS.—LOCAL CLASSES.

The competition was not less keen in the classes limited to cultivators resident within twenty miles of Hull than in those open to all, and the blooms were, on the whole, of much merit. The prizes for eighteen Japanese brought a keen contest, and at the head of the several exhibitors was Mr. G. B. Burrows, gardener to Miss Bennett, Westlands, Grimsby, who had grand blooms of well-known varieties. Mr. J. W. Backhouse was a capital second, and Mr. C. Storry, gardener to the Right Hon. T. R. Ferens, M.P., Holderness House, Hull, was a close third. In the class for twelve incurved, Mr. T. Hardcastle, gardener to A. S. Ayre, Esq., Tower Hill, Hessle, occupied the post of honour with remarkably well-finished blooms; and Mr. G. B. Burrows and Mr. J. W. Backhouse, who were second and third, had flowers of high quality. The prizetakers for six incurved were the exhibitor last named, Mr. T. Hardcastle, and Mr. J. Beet, 12, Church Lane, Hedon. There were thirteen exhibitors in the class for six vases of naturally-grown single chrysanthemums, and those successful were Mr. W. R. Tranmer, Mr. H. Taylor, and Mr. W. S. Drewery, 64, Hallgate, Cottingham. For the prizes for six vases of decorative chrysanthemums, disbudded, there was also a keen contest, and especially fine were the flowers shown by Mr. W. R. Tranmer, Mr. A. Drewery, and Mr. J. E. Gibbins, Halcyon Avenue, Hessle.

The amateurs exhibited with much success in the classes provided in this section, there being from ten to twelve entries in each class. Mr. T. Lazenby, 21, Beverley Road, Hessle; Mr. D. Wyllie, 3, The Limes, Hull; and Mr. J. A. Tholander, Anlaby Park, Hull, were the most successful exhibitors of Japanese. Mr. H. H. Barlow, Devonport Avenue, Hessle; Mr. W. Grasby, Studley House, Plane Street, Hull; and Mr. J. Bilton, Paisley Street, Hull, had the best incurved. The chief prize-takers for decorative and single varieties were Mr. J. A. Tholander, Mr. T.

Lazenby, Mr. J. Cummings, Holderness Road, Hull; Mr. W. Smith, Arnold Lane, Hull; and Mr. C. J. Mudd, South Street, Cottingham.

GROUPS ARRANGED FOR EFFECT.

Groups, which from the first have been a strong feature at the Hull shows, were of quite exceptional merit, and the eight or nine arrangements converted the floor of the great hall into a delightful flower garden. The chrysanthemums had to be arranged in a square, ten feet by ten feet, and to be interspersed with fine foliage plants. Artistic arrangement had to be the primary consideration in making the awards, but the exhibitors did not lose sight of the fact that high quality is also an important factor. The conditions of competition did not allow of any great variation in design, but there was a considerable difference in detail, and a remarkable freedom from sameness. In all cases the chrysanthemums were arranged to form a pyramid of flowers and foliage, rising to a height of nine feet, surmounted by a feathery palm, with a fringe of fine foliage plants at the base, and small groups of flowers and foliage at the corners. Japanese varieties predominated throughout, but singles were used, and their lightness added much to the general effect.

Councillor T. M. Petch, St. John Street, Bridlington, was successful in obtaining the premier award, which included a handsome silver cup, presented by the President of the society, with an arrangement that was singularly beautiful. Mr. H. Walmesley, gardener to Mrs. R. Molescroft, Beverley, was a very close second with an effective arrangement, and Mr. G. Jarvis, gardener to Mrs. Whitaker, Cliff House, Hessle, and Mr. W. Smith, who were third and fourth, also had arrangements in which both taste and cultural skill of a high order were well represented.

The competition for the prizes for mirror groups was even more keen than last year, and the ten or eleven arrangements placed in front of the pillars supporting the galleries produced a delightful effect. Mr. G. C. Coates, gardener to E. H. Holmes, Esq., Shalem House, Hull, was a capital first; the sides of the mirror were lightly decorated with single chrysanthemums, the top surmounted by medium-sized plants of choice nephrolepis, and at the foot was a group of various flowering plants. Mr. G. Wilson was a close second, the chief decoration being finely-grown poinsettias; and Mr. C. Storry, who was third, employed calanthes and cattleyas with good effect.

FLORAL DECORATIONS.

These, as usual, constituted an important feature, and received a full share of attention from the visitors. Seven ladies competed in the class for a table completely laid out for dessert, and much taste was evinced in the several arrangements. Mrs. Edwin Robson, Tower Grange, Hull, was successful in winning the first prize, which consisted of an epergne and a sum of money, Mrs. C. M. Bilton, Eastwood, Hull, following closely for second place. Mrs. R. Leech, Victoria Avenue, Hull, and Miss E. F. Harland, The Sycamores, were the most successful of the competitors in the class for an epergne, and for a tasteful arrangement of cut flowers in a table space of nine square feet the exhibitor last-named obtained the premier award. In competition for the prizes for a demonstration of the decorative value of chrysanthemums, Mr. M. Slather was successful in winning the five-guinea silver cup. Mr. H. Taylor contributed the best of the thirteen baskets of single chrysanthemums, and also the best hand bouquet.

FRUIT AND VEGETABLES.

Fruit was plentiful and good, the grapes being highly meritorious. Mr. McPherson, gardener to the Earl of Londesborough, Market Weighton, was first for white grapes with well-finished Muscat of Alexandria; and second and third prizes were awarded Mr. A. Mayfield, Beverley Road, Hull, and Mr. W. Boyes, Middleton-on-the-Wolds. Mr. Blakley, gardener to G. H. Shaw, Esq., Howden, York, scored for black grapes with finely-finished Alicante. Mr. McPherson staged splendidly-finished fruit of Peasgood's Nonsuch, Charles Ross, Gascoyne's Scarlet, Ribston Pippin, Cox's Orange Pippin, and Caville Blanc for first place in the class for six dishes of apples, three each of cooking and dessert. Mr. G. W. Musk was a good second. These two exhibitors were first and second also for three dishes of pears; and Mr. McPherson was first for a single dish of pears, staging Beurre Diel at its best.

Vegetables were represented by fine collections of eight kinds, and the best were those staged by Mr. A. Blakley, Councillor Petch, and Mr. J. Beet.

Bolton.

NOVEMBER 21 and 22.

This twenty-seventh exhibition was held in the Town Hall, and the system of arrangement underwent some slight alteration, which did not add to the attractiveness of the show. The groups of chrysanthemums gave way to a table, 8ft. long, 6ft. wide, and 2ft. high, and, with the exception of the winning exhibit, but little taste was shown, and the drapery required considerable modification.

Groups are usually excellent, and in fair numbers, but this year a considerable falling off was noticeable, especially in the 12ft. group, described in the schedule as "an artistic arrangement." The prizes are £10, £6, and £4, with a silver challenge cup added to the first prize. Only one exhibit was staged, and between four to six o'clock on the first day no prize card was on the group; but we gathered that the display was staged by Mr. H. Shone, gardener to J. W. Makant, Esq., and that there had been some difference of opinion as to what the award should be, and it was generally supposed that only second prize was awarded, the first prize being withheld. There were four judges, but how many adjudicated upon this entry we do not know. The group in question could not be compared to Bolton's best efforts, but it was an open question whether such drastic action was not too severe; at any rate, the popular opinion appeared to side with the exhibitor, and with it we agree. The group was a flat one, relieved by numerous dot plants, and with an arch having a twelve-foot span. Crotons were good in colour, and fairly numerous; palms, ferns, and dracænas were fresh and bright; oncidiums and Roman hyacinths were the most prominent flowers.

For a semi-circular group of chrysanthemums, Mr. B. Hardy, gardener to Gerard S. Peck, Esq., led with a bright, telling arrangement; Mr. E. Wilson, gardener to Miss Anne F. Phillips, second. Mr. H. Shone was well ahead, both in quality of flowers and lightness of arrangement, for a table of cut chrysanthemums. Mr. J. McCartney led for orchids, and Mr. J. Entwistle for carnations.

Mr. W. Foster had the leading primulas, Roman hyacinths, and dinner-table plants. Mr. W. Austin, gardener to Lever Tillotson, Esq., led for begonias, and Mr. D. Wilson had the best palms.

Mr. H. Wainwright was successful for two large-flowering chrysanthemums, three singles, one Japanese, and one single specimen, showing moderate plants throughout.

When it was generally known that Messrs. C. Chandler, C. Goves, G. Haigh, and C. Jones were likely exhibitors of cut blooms, a keen competition was anticipated, and this anticipation was fully realised, although the flowers were not equal to those staged at earlier shows. For twenty-four blooms, twelve incurved and twelve Japanese, Mr. C. Goves, gardener to Sir Gilbert Greenall, Bart., maintained his high position with a good, even stand, the best varieties being Lady Talbot, F. S. Vallis, and W. Turner; Mr. G. Haigh, gardener to Sir W. H. Tate, Bart., second, with good blooms; and the remaining award fell to Mr. A. Chandler, gardener to A. James, Esq. For thirty-six Japanese blooms, the prizemen were Messrs. C. Jones, A. Chandler, and G. Haigh; there were three good stands, and only a moderate margin divided them; the best flowers were F. S. Vallis, W. Mease, Mrs. G. Drabble, and W. Turner.

For six vases of singles, undisbudded, the prize-takers were Messrs. R. Tyrer, J. Nixon, and J. Parkinson, all of whom staged large bunches. Messrs. R. Tyrer, J. Parkinson, and H. Shone scored for six vases of decorative varieties.

Other first prizemen were Mr. S. Grundy, stove and greenhouse cut flowers; Mr. S. Lowe, table of orchids; Mr. W. Astley, two orchids; and Mr. W. Byrom, gardener to Viscount Brakley, three vases of single blooms.

Mr. H. Shone led with a finely-finished pair of Alicante, followed by Mr. W. Burgess, gardener to W. J. Harewood, Esq., in the class for black grapes, while for white grapes Mr. J. Wright, gardener to Edmund Lord, Esq., led with Muscat of Alexandria, with Mr. Thomas Barclay second.

Blackburn.

NOVEMBER 21 and 22.

The Town Hall looked especially bright and attractive on the occasion of the seventeenth exhibition of this society, and the Staging Committee deserve much credit for the able way in which they arranged the exhibits. In front of the platform three large groups of chrysanthemums were staged, the centre one of single varieties, and the two others of Japanese blooms. With a width of 30 feet, and ten feet in height, these gave an imposing effect. The other end of the hall contained a charming bank of orchids eight feet in width, supported on either side by mirror groups.

Cut blooms are overshadowed at this show by the orchids, yet good stands were staged. For twenty-four Japanese, distinct, Mr. H. Boyd, gardener to Captain Feilden, was the leader, with a box of good blooms, his best being Lady Talbot (which secured the certificate for the best bloom in this section), and Mrs. G. Drabble. Mr. J. Pimlott, gardener to T. Mitchel Eccles, Esq., was a close second. For two doxen incurved varieties, Mr. R. H. Jones, gardener to A. E. Troop, Esq., was to the fore with good blooms, and his Mrs. J. Hygate took the certificate for the best incurved bloom in the show; Buttercup and Golden King were also noteworthy. Mr. J. Pimlott was again second.

For twelve Japanese, Mr. H. Boyd still held his own, and for six blooms Mr. C. Samways, gardener to J. Thompson, Esq., took the lead; while for a dozen incurved, Mr. R. H. Jones led the way; and in the smaller class Mr. R. C. Bullock, gardener to Mrs. Astley, was the chief winner.

For one vase of Japanese blooms, Mr. H. Boyd scored; and for three vases of singles Mr. R. McCullock led. In two distinct classes for one vase of carnations, Mr. H. Boyd, and Mr. W. Wilkinson, gardener to J. Duckworth, Esq., won firsts.

Orchids are undoubtedly the feature of the show. In the class for a table of plants, already referred to, Mr. J. Lupton, gardener to Colonel J. Rutherford, M.P., well known as a grower of repute, won with a delightful blending of oncidiums, odontoglossums, lælias, etc., in many choice kinds. This exhibitor had clean wins for a table of cypripediums, three cypripediums, three hybrid orchids, four orchids, three oncidiums, and one orchid (Vanda cœrulea with two spikes of large flowers), the only exception in the case being Mr. W. Hough, gardener to Miss Armistead, who beat Mr. Lupton for one cypripedium.

For a table of begonias, Mr. C. Samways won, whilst Mr. Bradburn had the leading six Primula obconica, a splendid strain; and Mr. J. Bartlett, gardener to H. Shutt, Esq., won for Roman hyacinths.

In the class for an oval-shaped group of miscellaneous plants (nurserymen only), Mr.

Thomas Berry proved the victor, and utilised good heaths and orchids; Messrs. Edward Ledge and Son second. The best group of large-flowering chrysanthemums came from Mr. H. Bradburn; and Mr. J. Pimlott was second with good, but smaller flowers. For a group of singles, Mr. C. Samways was the only exhibitor, but staged a fine exhibit that merited the first prize.

Mr. H. Bradburn continued his successes for chrysanthemums in pots, winning for six pots (singles), four pots (large-flowering), two Japanese, one Japanese, one incurved, and one single, and the N.C.S. Silver Medal for the best plant in the show for the variety Miss Alice Finch. This exhibitor proved the leader for four salvias and three bouvardias, but Mr. R. McCullock led for cyclamen, Mr. H. Boyd for begonias, and Mr. C. Samways for amaryllis.

Some tasteful arrangements were made with cut flowers, and Mrs. Pimlott held the position of honour with a charming basket of chrysanthemums; Miss Hilda Howard leading for autumn foliage and berries, and Mrs. H. Arthur for a table centrepiece.

Mr. W. Eastwood, gardener to H. H. Bolton, Esq., proved the winner for two bunches of black grapes, and Mr. J. Wright, gardener to Edmund Lord, Esq., scored for white grapes.

Mr. H. Wells, gardener to A. T. Walker, Esq., had the winning set of eight dishes of vegetables and the finest onions.

Newport (Mon.) Chrysanthemum Society.

This society's annual show on November 1, held in the Gymnasium, Newport, was most successful. The cut blooms were not quite so good as they have been sometimes at Newport, but they were, nevertheless, excellent. There was an increase in the number of exhibitors, the classes generally were well filled, and the attendance satisfactory.

GROUPS.

Only one entry was made in the class for a group of chrysanthemums and foliage plants, arranged on 50 square feet, and it was from Mr. W. Pearce, gardener to H. Oakley, Esq., who arranged an effective collection of well-grown plants, including Japanese and single chrysanthemums, crotons, dracænas, palms, etc., a background of papyrus, and an edging of ferns and panicum, the whole crowned with a fine specimen of Phœnix rupicola. In the class for a group of chrysanthemums, to fill 40 square feet, only one exhibitor put in an appearance, viz., Mr. R. Long, gardener to W. F. Dawson, Esq., who had a fine exhibit, well arranged, with colours nicely blended, and splendidly furnished with foliage.

There were four groups of single chrysanthemums, and Mr. W. Pearce had the best, though the plants were somewhat large, and were crowded; Mr. S. Rumney, gardener to G. H. Ingham, Esq., was a close second with a group containing similar defects; Mr. Harris, gardener to E. Phillips, Esq., third, with well-grown plants, too thinly arranged. In the class for a group of chrysanthemums, arranged on 20 square feet, Mr. J. H. Broom led with a pleasing arrangement of large, finely-coloured blooms; Mr. F. J. Richards was a good second, and Mr. W. Shipton, jun., third.

PLANTS.

Three bush plants, single varieties, made a good class, as three sets were staged, Mr. R. Long taking the lead with large, freely-flowered plants of excellent varieties; Mr. F. S. Daniels, gardener to F. Phillips, Esq., with still larger plants, but the varieties not being so good, was placed second. In another class of the same description, Mr. Daniels was an easy first with capital plants carrying good blooms and well clothed with foliage; Mr. R. H. Smith followed with smaller plants. For two plants Mr. F. J. Richards was placed first, and Mr. R. H. Smith second; and for a single plant of any variety, Mr. J. H. Broom was first, and he also scored for a single variety.

CUT BLOOMS.

Three splendid sets were staged in the class for eight vases of Japanese varieties, three blooms in each vase. Mr. E. J. Spencer, gardener to H. A. Tipping, Esq., led with large, deep, and finely-coloured blooms of F. S. Vallis, Mrs. H. Stevens, Lady Talbot, Mrs. G. C. Kelly, H. E. Converse (fine), Mrs. Gilbert Drabble (extra good), and Splendour; Mr. R. Long was a very close second, being only one point behind Mr. Spencer with Maud Jefferies, F. S. Vallis, Mrs. Gilbert Drabble, Fred Chandler, F. T. Mew, etc.; Mr. Daniels third.

Of four vases of Japanese blooms there were four exhibits, and Mr. S. J. T. Grinter scored with fresh, solid blooms of W. Turner, Lady Talbot, W. Mease, and F. S. Vallis; Mr. W. H. Hollingdale was a close second, and Mr. S. Rumney third. Mr. Luffman was the only exhibitor of two vases, Japanese, and staged Mrs. G. Drabble and W. Turner in fine condition. One vase, Japanese, brought four entries, among which Mr. E. W. Kirby took the lead, Mr. A. H. Jones being second.

The classes for single varieties were very popular. The one for four vases found Mr. J. Matthews taking the lead with Mensa, Mrs. Buckingham, Metta, and Kitty Bourne; Mr. R. Fry was second, and Mr. Smith third. Mr. Sharratt, gardener to J. E. Webb, Esq., was placed first in a class for six vases of single varieties, and staged Metta, Coronation, Altrincham Yellow, Mrs. Hartley Bills, Mrs. H. S. Berens, and Snowflake in fine condition; Mr. Long second, and Mr. Wiggins third. Mr. Long secured the lead for three vases of singles, staging Crown Jewel Improved, Kitty Bourne, and Metta.

Apart from the vases the chief class was for twenty-four Japanese blooms, and here there were three exhibitors, the leader being the Manor House Nurseries, Lim., Cardiff. Fine, weighty blooms were staged, chief of which were Lady Talbot, Master James, Mrs. Drabble, W. Turner, John Howe, A. Robertson, Mrs. R. Luxford, Mrs. G. C. Kelly, Fred Green, Rose Pockett, and Miss Annie Nicoll. Mr. F. S. Daniels was a good second; and Mr. J. B. Greening, gardener to the Rev. W. M. Willett, third. There were seven competitors in the class for a dozen Japanese, distinct, and here Mr. Long led with a good set, including Mrs. F. S. Vallis, Fred Chandler, W. Turner, Lady Talbot. Mr. F. S. Vallis, and Bessie Godfrey; Manor House Nurseries, Lim., second, and Mr. King, gardener to Dr. J. Cropper, third. Twelve Japanese, not less than four varieties, found Mr. S. T. Collings taking the lead. For six blooms, Japanese, Mr. E. W. Kirby led, and he also secured the National Chrysanthemum Society's Certificate for the best bloom in the show, with a perfect example of W. Turner; and Mr. J. H. Broom secured a similar award for the best plant. Both these exhibitors are cottagers.

ORCHIDS.

Two fine groups of orchids were arranged, the best coming from Dr. Brooke Gratte, who had oncidiums, odontoglossums, cattleyas, cypripediums, and cymbidiums as principal subjects; Mrs. C. D. Phillips (gardener, Mr. J. Massie) second. For three plants, Mr. Massie scored with well-bloomed examples of Oncidium varicosum Rogersi, O. Forbesi, and Cypripedium Leonie; Mr. E. Fowler, Pontypool, second, with Cattleya Portia and Oncidium Forbesi.

In the floral decoration section Mrs. Preece, Miss Greening, Mrs. R. Long, Miss A. M. Harding, and Mr. G. H. Holbrook were the chief prizewinners.

FRUIT.

Mr. George, gardener to H. F. S. Freeman, Esq., was first for black grapes with Alicante, Mr. Daniels second with Gros Colmar. Mr. Daniels led for white grapes with Muscat of Alexandria, and Mr. George came second. Mr. G. Griffiths was first, and Mr. T. Hutchins, gardener to Colonel Wallis, second, for a collection of fruit. Mr. Griffiths scored for pears, and Mr. Hobbs for apples.

Chester Paxton Society.

NOVEMBER 18 and 19.

This society's annual chrysanthemum show was held in the Town Hall. Fruit, as usual, occupied a large amount of space, and the quality generally was well up to the average.

FRUITS.

Mr. R. Jones, gardener to J. Amplett, Esq., secured the leading award for two bunches of black grapes with large, well-finished bunches of Alicante; Mr. H. W. Bromley was second with the same variety; and Mr. W. Pilgrim, gardener to Sir George Merrick, third, with Appley Towers. For two bunches of white grapes Mr. W. Pilgrim and Mr. R. Jones were first and second, both staging Muscat of Alexandria, the winning set being of fine colour.

For six dishes of dessert apples, Mr. J. Shaw, gardener to G. Fitzhugh, Esq., led with a highly-coloured set, Rival and Cox's Orange Pippin being excellent; Mr. G. Bridgewater, gardener to E. Porritt, Esq., was second; and Mr. J. Thompson, gardener to H. E. Welbraham, Esq., third. The best twelve dishes of kitchen apples came from Mr. R. R. Saleman, with Mr. J. Fleet second. For six dishes of kitchen varieties the prizetakers were Messrs. J. Weaver, T. Day, and R. Jones.

In the class for a collection of twelve dishes of kitchen apples, six of dessert apples, and six of dessert pears, there was a fine display, and Mr. W. Pilgrim proved the victor by staging excellent Peasgood's Nonsuch, Warner's King, Mère de Ménage, Charles Ross, and King of the Pippins apples, and Beurre Diel, Charles Ernest, and Doyenne du Comice pears. The remaining awards went to Messrs. G. Bridgewater and R. Jones. Messrs. J. Fleet, G. Bridgewater, and T. Gilbert were placed as named for six dishes of dessert pears.

In the single dish classes the most noteworthy were Cox's Orange Pippin, from Mr. J. Shaw; King of the Pippins, from Mr. J. Thompson; Peasgood's Nonsuch, from Mr. W. Pilgrim; Chas. Ross, from Mr. G. Bridgewater; James Grieve, from Mr. A. Billington; Loddington, from Mr. C. C. Dennis; and Warner's King, from Mr. B. Kerr; Beurre Diel pears, from Mr. W. Dodd; and Catillac pears, from Mr. W. Pilgrim.

Mr. H. Bayfield was first for boxes of fruit, as packed for market, with King of the Pippins.

GROUPS AND PLANTS.

For a group of single-flowering chrysanthemums, Mr. F. Berry, gardener to J. R. Samuel, Esq., was first with masses of colour; Mr. J. Martin second. For a group of naturally grown chrysanthemums, Mr. T. Gilbert, gardener to T. Gibbons Frost, Esq., was the winner with finely-coloured blooms artistically arranged.

Mr. J. Fleet took the lead for six pots of single chrysanthemums with excellent plants carrying an abundance of bloom. For six table plants the prizemen were Messrs. W. May, A. Billington, and F. Berry.

CUT FLOWERS.

The best eighteen blooms, Japanese, three blooms in a vase, were set up by Mr. T. Winkworth, gardener to R. Brocklebank, Esq., and he was well ahead with good examples of F. S. Vallis, W. Turner, and Lady Talbot; Mr. E. Bennett, gardener to J. E. Gordon, Esq., and Mr. W. Dodd, gardener to E. Peter Jones, Esq., followed in order. For a dozen Japanese blooms, set up in five vases, Mr. T. Winkworth maintained his position; and for five blooms Mr. J. Fleet led the way. For five incurved, distinct, Mr. T. Winkworth was again to the fore, staging good Clara Wells and C. H. Curtis.

For twelve Japanese blooms, staged on boards, Mr. W. May, gardener to W. Dronsfield, Esq., had the best set; and for six vases of naturally-grown flowers, other than singles, Mr. T. Sanders, gardener to Captain W. G. Townsend, won with a grand lot; while for the six vases of single varieties, A.

D. Pitcairn Campbell, Esq., took the lead with a charming exhibit.

For the best table of naturally-grown chrysanthemums, Mrs. Willett led with a pleasing arrangement; and for a table of flowers, chrysanthemums excluded, Miss N. Denson was to the fore with carnations and lily of the valley.

NON-COMPETITIVE.

Mr. G. Porter, gardener to A. Hanmer, Esq., was awarded a gold medal for a table of choice orchids in great variety. The British Columbia Government also secured a gold medal for a large collection of highly-coloured apples. Mr. W. E. Sharp, gardener to W. Richardson Moss, Esq., was awarded a silver medal for a table of plants. Messrs. Dicksons, Chester, had a fine bank of chrysanthemums, liliums, and begonias; and Messrs. McHattie set up a collection of chrysanthemums, carnations, etc.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE.—November 4.

Present: Mr. E. A. Bowles, M.A., in the chair; Sir Everard im Thurn, Messrs. C. E. Shea, J. T. Bennett-Poë, R. H. Pearson, A. Worsley, E. M. Holmes, J. Fraser, G. Wilson, G. Gordon, and F. J. Chittenden (hon. sec.).

DECAISNEA FARGESI FRUITING.—Mr. R. W. Wallace exhibited fruits of Decaisnea Fargesi from a garden in the East of England. The curious bean-like, but fleshy fruits of this berberidaceous plant are produced frequently in the West of England, but this is the first instance known to any member of the committee of their ripening in the open in the East.

SCENTED-LEAVED PELARGONIUMS.—Mr. J. Fraser continued his observations on the history of these plants in gardens, illustrating his remarks as usual by means of beautifully dried specimens from the Wisley collection.

QUILLED CHRYSANTHEMUMS. — Mr. Worsley showed flowers of quilled chrysanthemums from his garden, where he had none hitherto, these having been raised from seeds ripened there, and apparently from plants not crossed with any quilled form. Mr. Shea remarked that chrysanthemums rarely set seed without cross-pollination, and suggested that the pollen may have been brought by insects from a neighbouring garden. The earliest drawing of a chrysanthemum was exhibited, and apparently showed traces of quilled flowers, so that the early-introduced plants no doubt brought this character with them.

CARNATION - CHRYSANTHEMUM GRAFT.—A correspondent from Greenock sent chrysanthemum flowers from plants which he had grafted on carnation stocks, and said that the flowers varied from those of the plants from which the scions were taken. The committee were unable to see whether the grafting had actually occurred, or whether the scions had produced roots, and sought further information.

MULTIPLE PEAR.—Mr. Druery showed a multiple fruit of a pear formed from a summer flower in a garden at Acton. It appeared to consist of parts of four pears in close contact, but was no doubt derived, partly at least, from the cortical tissues of the lower parts of the flower-stalk.

PELORIC CATTLEYA.—Mr. G. Wilson showed a peloric form of Cattleya labiata alba, remarking that peloric forms of albinos were decidedly rare.

IRESINE SPORTING.—Mr. Longmine, of Clapham Common, showed a shoot of Iresine acuminata, in which the normal red foliage had been replaced on one side of the shoot by green leaves, yellowish along the veins. The leaves and shoots were arranged so that alternate leaves on the one side of the stem were green, while the intervening leaves were half green and half red. The shoots in the axils of these leaves were green, or half green and half red respectively. Shoots propagated came true to these variations.

Edinburgh Royal Botanic Garden Guild.

This newly-formed guild of past and present employees of the Edinburgh Royal Botanic Gardens, celebrated the end of its first year of existence by a dinner in the Royal British Hotel on the evening of Friday, the 14th inst. Mr. W. W. Smith, Assistant Keeper of the Gardens, occupied the chair, in the unavoidable absence of Prof. Bayley Balfour, the hon. president of the Guild. After an excellent repast, and honouring the loyal and patriotic toasts, Dr. Borthwick proposed the toast of "Our Honorary President, Professor Balfour," so widely known for his great botanical and horticultural attainments, and who was worthily keeping up the long-known fame of the gardens. He had done much for the practical and theoretical education of the young men under his charge, and was warmly in favour of the formation of a guild to bind together in the bonds of brotherhood the large number of past and present employees. The toast was honoured with great enthusiasm. Afterwards the guest of the evening, Mr. J. Mc.Hattie, the popular City gardener of Edinburgh, proposed "The Guild," in a neatly-expressed and apropos speech, wherein he urged the young men to secure every educational advantage the garden afforded, and to equip themselves for life by study in the many educational institutions of Edinburgh. They were the future horticulturists, and should see they were thoroughly able to maintain the fame of the Edinburgh gardens. Mr. R. L. Harrow, the Curator, replied to the toast. Other toasts, including that of "Our Guest," were honoured, and with songs and speeches a very pleasant evening was spent.

The Horticultural Club.

On Tuesday, the 18th instant, this club held its usual monthly dinner at the Hotel Windsor under the presidency of Sir Frank Crisp, Bart., and there was a good attendance of members and guests.

Subsequently to the dinner, Mr. Reginald Farrer gave a lecture entitled "Not about Switzerland," explaining that the vagueness and widely-extended implication of the title was due to the fact that he was always being asked about Switzerland, to the exclusion of other Alpine regions, and desired to give some indication that the other mountain ranges had floras of their own with which he had ventured to make some acquaintance.

In eloquent language he gave many details of his travels and researches in connection with alpine plants in the extensions of the Alpine ranges beyond the Swiss limits, and the peculiarities which he had noted in his travels with regard to the plants he discovered, and the failures and successes which eventually attended the transference of these plants to the lowland conditions of his home collection. Amongst other things he combated the general opinion that the whole of the primula family required moist and protected environment, as most of them, he found, did well in positions well exposed to the sun, and not always in a soaked soil. The general essential condition of a long and uninterrupted resting period was treated of. He also dealt with botanical differentiation, challenging in several cases the correctness of the specific names often given to simple varieties of one and the same species or the confusion of one species with a really distinct one. In order to have a fair opportunity of widening his experience of alpine plants, he was on the point of going to Thibet to familiarise himself as far as possible with the Asiatic alpine flora in its native habitats, and promised on his return to give the club an account of the results, a promise received by the audience with great gratification.

In the subsequent discussion Sir Frank Crisp, and Messrs. Bilney, Hoog, C. Pearson, and Clarence Elliot participated, giving their own particular experiences in connection with the fascinating study of the alpine flora under cultivation and in its native homes, all those who had seen it under the latter conditions agreeing in their high appreciation of its wondrous beauty, variety, and frequent abundance. The counsel was given, and approved by all, that it is not advisable to collect long-established plants for transference, but that young ones should be chosen, the roots of the former often penetrating so deeply in course of time as to render extraction impossible, the result being failure.

Sir Frank Crisp proposed a very cordial vote of thanks to the lecturer, and expressed the hope that his journey to Thibet might prove a very successful and enjoyable one, and that his promise of an eventual lecture might be fulfilled.

Bournemouth Gardeners' Association.

A very interesting and instructive lecture on zonal pelargoniums for summer and winter flowering was given by Mr. G. H. Heath, Glenfallock Gardens, Bournemouth, on Tuesday, November 18, before a good attendance of members.

Twenty-four dishes of splendid apples were sent by Messrs. George Bunyard and Co., Lim., Maidstone.

At the close of the lecture the members bought the fruits, the money resulting being sent to the Gardeners' Orphan Fund. A hearty vote of thanks was passed to Messrs. Bunyard for so kindly sending the apples.

In the "points" competition class, cypripediums were shown by Mr. Smith, gardener to the Dowager Lady de Tabley; zonal pelargoniums by Mr. Heath; and crotons, ferns, and a pandanus, by Mr. C. Pearce, gardener to Mrs. Ormond, Astney Firs; Mr. Heath also staged nine vases of distinct varieties of pelargoniums, with their own leaves, and the effect was very good.

The lecturer is a very successful cultivator of zonal pelargoniums, and he advised lovers of this flower to strike cuttings in July for summer-flowering, and in August for autumn and winter-flowering. For a general compost he recommended turfy loam three parts, leaf-soil one part, with a sprinkling of old lime and a small quantity of bone-meal. Firm potting was essential. The plants should be topped when small, and again when potted into their flowering pots. A small quantity of sulphate of ammonia intensified the colour of the blooms, but the lecturer said he mainly used potash, and phosphatic manures. Nitrogen produced large leaves. A free discussion ensued, and very hearty votes of thanks were accorded the lecturer, and Mr. G. Garner, who presided.

Morley Paxton Society.

This society held its ninth annual chrysanthemum show in the Alexander Hall at the Town Hall on Saturday last, and broke all previous records in the number of exhibitors and the number of exhibits, also in the quality of the blooms.

In the cut blooms Sir Wm. Bass, Bart., took first place both for Japanese and incurved, and obtained the National Chrysanthemum Society's certificate for the premier bloom with Mrs. G. Drabble; Miss Bennett, of Grimsby, was second for Japanese, and Mr. John Thornton, of Drighlington, second for incurved. In the classes for singles, Mr. John Hartley, of The Knowle, Morley, followed up his successes at Leeds and Bradford by taking firsts in almost every class.

A feature of the show was the number (10) of groups put up in the local classes, four being from cottagers, W. Lassey winning outright the Ward Brook silver challenge cup, having won it three times in all; he was followed closely by Mr. E. Ambler, who had won this cup on two previous occasions.

The Borough Gardener added to the attractiveness of the show by a magnificent display of chrysanthemums and foliage plants arranged in a mass in front of the wide platform, and plants and liliums on the platform.

The attendance of the public was phenomenal, the great crush being the only drawback to a most successful show.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of THE GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notifications of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming, or opinion, should be sent to the Editor of THE GARDENERS' MAGAZINE, 2, Adelaide Road, Brentford, Middlesex, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in THE GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

BLOTCHED CAMELLIA LEAVES.—E. G. C., Dover: Kindly tell me what causes the unsightly blotches on the camellia leaves enclosed. For some years we have annually seen leaves similarly blotched, and though no great harm appears to be done, even a few damaged leaves make a plant ugly.—The blotches are due to the presence of a fungus named Pestalozzia Guepini, a disease which, fortunately, does not do much damage to camellias, though we believe it has been the cause of considerable loss in some tea plantations in India. The best means of checking it is to remove and burn all diseased leaves, and keep the plants scrupulously clean at all times of the year.

CLIMBING ROSES FOR A NORTH ASPECT.—J. K., Northampton: Please let me know, through your columns, whether any climbing roses are really suitable for cultivation against a wall facing north; and, if so, the best varieties.—The best roses for cultivation in a north aspect are Ards Rover, Bennett's Seedling, Climbing Aimée Vibert, Felicite et Perpetue, and Gloire de Dijon, respectively H.P., Ayrshire, noisette, sempervirens, and tea-scented varieties. You may try these with every prospect of success provided suitable preparations are made for them, and a first-rate rooting medium is provided.

BEETLES IN HOTHOUSES.—H. C., Leicester: I am sending, in a tin, some beetles which infest our hothouses. We were not troubled with them until about seven years ago, and I think they must have been introduced with some cocoanut fibre refuse, as the first specimens found were in the fibre on some lily of the valley we were forcing, and the bulk of which the pests ate away. They are most destructive things, and nothing in the form of vegetation comes amiss to them. They are far worse than woodlice, even attacking hard-wooded plants, and barking the crotons. We have tried the usual remedies, such as pouring boiling water in their haunts, and trapping with hollowed potatoes, and thought we had got rid of them, but find, like the poor, they are always with us. I shall be very grateful for any suggestions you can give me for clearing out these unpleasant creatures. You will notice, perhaps, that the beetles bury themselves instantly in loose material if frightened, and, I may add, that they mostly frequent a hot, dry place, where there is loose plunging material.—The pests seem to be allied to the cockroaches, and we noticed how speedily they bury themselves in loose soil. Any and every method should be adopted to eradicate them, and must be carried out regularly until there is no further fear of damage from them. Baits composed of arsenic or phosphorus paste may be used, provided household pets are not likely to eat them, and they will speedily answer for many of the beetles. Some of the proprietary articles should be tried, as well as the traps offered by the horticultural sundriesmen who advertise in our columns. We remember how, some years ago, we trapped hundreds of somewhat similar pests by filling shallow, stout tin boxes with the decayed fibre-refuse in which they seemed to delight; having filled the tins, they were buried in infested places, or placed wherever the beetles mostly gathered. About every third day the tins were removed, and their contents thrown into the furnace fire; this means, and the use of phosphorus paste, eventually relieved us of unwelcome guests.

THE NARCISSUS FLY.—E. G., Potters Bar: Will you kindly tell me whether there is any Governmental publication, either from Kew or the Board of Agriculture, dealing with the Narcissus Fly, as I am anxious to get together all the information possible concerning this pest?—In the October issue of the "Journal" of the Board of Agriculture there is an illustrated account of the Narcissus Fly (Merodon equestris), by Dr. R. S. MacDougall.

REMEDY FOR CARROT FLY.—J. M., Weybridge: In our district it is a very difficult matter to obtain good crops of carrots; the seeds seem to germinate all right, but before very long the young plants sicken, and even if a few roots do come to any size they are grub-infested, and practically useless. Can you suggest any means whereby the carrot crop may be safeguarded next year?—In the case of carrot crops suffering from attacks of the Carrot-Fly (Psila rosæ) little can be done to remedy the trouble, but a great deal of good will result if proper preventive measures are adopted. Where carrot crops have been infested with the carrot-fly the ground should be heavily gas-limed at once, and then deeply trenched, the surface soil being placed in the bottom of the trench, so the hibernating pupæ which escape the gas-lime are buried out of the way. The carrot-fly has a strong dislike to paraffin, and so it is an excellent plan to mix about a quart of paraffin with a small barrow load of finely-sifted dry wood ashes, and apply a dressing of the mixture over the plot as soon as the carrots have been sown. A similar dressing should be given when the carrots are two inches high. When thinning the carrots, promptly fill up the holes from whence carrots are drawn with fine soil; thinning finished, draw a little soil towards the rows, and follow with a good watering. By these means the efforts of the carrot-fly to deposit her eggs are frustrated. In badly infested districts we should give a third dressing of the paraffin and ashes directly after the thinning and watering.

COLOURED SYMPHORICARPUS BERRIES.—Mr. W. Judd, Arnold Arboretum, Mass., U.S.A., writes: "Referring to one of your October issues, may I point out to a correspondent that the fruits of Symphoricarpus vulgaris are not white, but red. Here, around Boston, the plant is very common, and is locally known as the Indian Currant. It looks particularly beautiful in early November, with its long, arching sprays of red fruits."

HOW TO DEAL WITH A HOLLOW IN THE TRUNK OF AN EVERGREEN OAK.—E. P., Margate.—I have a large evergreen oak, and about 3ft. from the ground it branches into three main stems, and in the fork there is a hollow, capable of holding about a gallon of water, and this fills up during wet weather. The tree is beginning to present an unhealthy appearance, which I attribute to the water standing in the hollow. Will you kindly tell me how I can best fill up the space, and what material to use?—Remove the water from the hole with a sponge, and scrape the wood quite clean, clearing away decayed matter and filth with a chisel, or old pruning knife. The hollow must then be left for a few days to dry, with a waterproof sheet, or other suitable material over it, to prevent water entering the hole. When quite dry, tar the inside of the hole thoroughly. Use gas tar, and take care to apply it to the wood only, and not to the bark. Allow this to dry, covering as before to keep out the wet. After a few days fill up the hole with a mixture of Portland cement and sand, bringing it up high enough to prevent water remaining in the hollow formed by the forked trunk. To make the surface more closely resemble the bark of the tree, mix a little lamp black, or soot, with the outer coating of cement.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

L. G. E., Hexham.—1, Browallia speciosa major; 2, Amaryllis aulica; 3, Euphorbia splendens; 4, Calanthe vestita rubro-oculata.

S. K., Norwich.—1, Oncidium varicosum Rogersi; 2, Cypripedium insigne Cobbianum; 3, a very poor form of Vanda cœrulea; 4, Fittonia argyroneura Pearcei.

S. S., Taunton.—1, Pelargonium Radula; 2, Origanum dictamnus; 3, Sibthorpia europæa; 4, Cupressus Lawsoniana Allumi; 5, Azara microphylla; 6, Cypripedium Maudiæ.

M. M., Windlesham.—1, Pernettya mucronata; 2 and 3 are the same species, but show different colouring in the berries; seedlings show this difference, and also some variation in habit.

COUGHS, COLDS,
ASTHMA, BRONCHITIS
and all kindred ailments are speedily relieved by

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, GARDENERS' MAGAZINE, as advised in the notice at the head of "Answers to Correspondents."

K. W. S., Reigate.—1, Bess Pool; 2, King of the Pippins; 3, Sturmer Pippin.

H. P., Aylesbury.—1, Fearn's Pippin; 2, Bismarck; 3, Royal Russet; 4, Adam's Pearmain.

F. F., Cirencester.—1, Blenheim Pippin; 2, Alfriston; 3, Lane's Prince Albert; 4, not recognised.

R. S. N., Tiverton.—1, a small Cox's Orange Pippin; 2, not recognised; 3, Mère de Ménage; 4, probably Betty Geeson; 5, Emperor Alexander; 6, Sturmer Pippin.

CATALOGUES RECEIVED.

DICKSON'S, CHESTER.—A very neat catalogue comes from Chester, devoted to ornamental and forest trees, shrubs, tools, and sundries.

GEORGE PRINCE, LONGWORTH, BERKS.—A boldly-printed rose catalogue, with the varieties fully classified, numerous illustrations, and a list of the firm's chief successes at exhibitions, including the D'Ombrain Trophy for tea roses won at the N.R.S. Show seven times in succession.

BERTRAND W. DEAL, BROOKLANDS, KELVEDON.—Mr. Deal is an extensive cultivator of seeds on wholesale lines, but in the matter of sweet peas he is a retailer as well as wholesaler, and in his new catalogue he lists a number of sweet pea novelties, as well as the general collection.

HERD BROS., PENRITH.—In addition to the descriptive list of forest trees, ornamental trees, fruit trees, etc., offered, and grown from 600 to 800ft. above sea level, this firm makes a special feature of offering collections of a hundred conifers, and a similar number of roses, of standard flowering and foliage trees, of flowering shrubs, and of herbaceous plants, at fixed rates.

JAMES DOUGLAS, GREAT BOOKHAM, SURREY.—The twenty-first annual catalogue issued from the Edenside Nurseries, Great Bookham, is worthy of the name it bears. In it carnations are classified, described, and, in some few instances, figured; there is an illustration of the Cartwright Cup won by the firm five years in succession. Auriculas and German irises are also included in the list.

R. WALLACE AND CO., KELNFIELD GARDENS, COLCHESTER.—Three catalogues from this Colchester firm prove interesting reading. One lists hardy bulbs, tubers, and rhizomes; another is devoted to hardy plants and alpines, while the third is a delightfully illustrated booklet on garden design, indicating the firm's work and successes in creating new and improving old gardens.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

MONDAY, December 1.—National Dahlia Society; Annual Meeting at the Hotel Windsor, Victoria Street, Westminster, at 4 p.m.

TUESDAY, December 2.—Royal Horticultural Society; Committees meet at 12 o'clock; Lecture at 3 p.m. on "Informal Garden Design," by Mr. Edward White; Scientific Committee at 4 o'clock.

Horticultural Club Monthly House Dinner at the Hotel Windsor, Victoria Street, Westminster, at 6.30 p.m., to be followed by a lecture, illustrated with coloured lantern slides, entitled "A Ramble along the West Coast of Vancouver Island," by Mrs. Julia L. Henshaw.

WEDNESDAY, December 3.—Perpetual-flowering Carnation Society's winter exhibition at the Royal Horticultural Hall, Westminster; Conference at 3 p.m., when Mr. G. H. Lawrence will read a paper on "Carnations for Amateurs, by an Amateur"; Annual General Meeting at 6 p.m.

THURSDAY, December 4.—Linnean Society meets.

SATURDAY, December 6.—French Horticultural Society of London.

BARR'S SPECIAL BULB PLANTER

Rd. 548091.

Specially designed for planting Daffodils and other bulbs in grass. This tool cuts and lifts a clean circular piece of turf, which is released from the cup when the second hole is made, and lies ready at hand to fill in the holes when the bulbs have been put in, it being only necessary to remove a little of the soil from the bottom of the sod. By its use a large quantity of bulbs may be planted in a very short time, and without the least disturbance of the sward. The cup is manufactured from high-class hardened steel, and always carries a keen cutting edge. 10s. 6d. each.—BARR and SONS, 11, 12, and 13, King Street, Covent Garden, London.

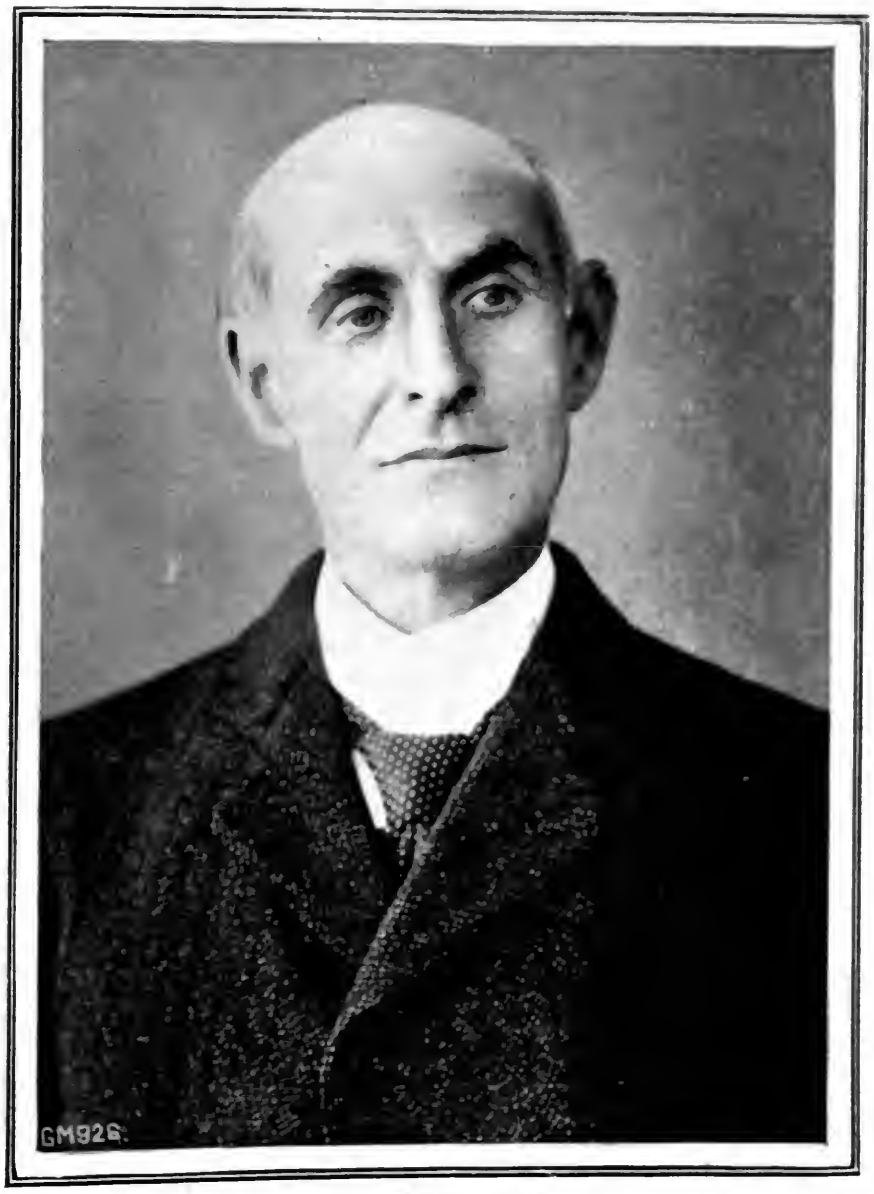
THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Protection for Horticultural Novelties.

Very many suggestions have been put forward from time to time for the purpose of arriving at a solution of the difficulties which always beset the raisers or introducers of horticultural novelties, but, so far, without success. It is interesting, therefore, to notice that a very powerful organisation is being formed on the Continent to take measures to secure to the raisers of such novelties the exclusive right of profiting by their new introductions for a definite period, much in the same way that authors of books and producers of works of art are protected under the Copyright Acts, national or international. This matter has more than once been raised at meetings of the Royal Horticultural Society, but, however much the desirability of such protection has been recognised, the fundamental differences between plants and books were too clear to admit of any probable solution of them, or of bringing the law to bear on anything like parallel lines. The first difficulty is that a novelty in the horticultural sense is not altogether the outcome of a human inspiration but a gift of Nature, no matter how far the cultivator may have formed an ideal beforehand, and by careful hybridisation, cross-fertilisation, or selection, attained it, or an approach to it which he deems worthy of note. Many other specialists may be simultaneously working on similar lines, and, as has often happened, reaped similar successes. Even with natural sports, as with Cytisus Andreanus, the red-flowered Broom, and some chrysanthemums, they may crop up at various places and be found introduced by several people at or about the same time. The organisation referred to aims at establishing priority in such cases, and, this established, would, we presume, prevent other raisers or finders from putting their prizes on the market. Would this be just? To secure such protection the distributor or raiser would have to exhibit his plants with as little delay as possible, and obtain a certificate long before he had any stock to dispose of, or, maybe, before its actual cultural value was established. Having obtained it, he might fail to raise any stock at all, but still the priority certificate would debar others from profiting by their labours, as their plants would be useless commercially, except by agreement with the holder of the certificate, to whom, in fact, they were not indebted at all. If, on the other hand, he, like a business man, and as is now done, refrained from putting his novelty forward until he had a stock to dispose of, he would then, of course, run the risk of a subsequent discoverer, or raiser, forestalling him. With the copyright of a book, or a work of art, the position is entirely different; a copy of the book is deposited, and is easily distinguished from every other book by the peculiarly individual features of the work itself, the author's name on the title-page, and, presumably, by the printer's name somewhere else, to say nothing of the publisher. With a plant the only thing that could be secured would be the name; but how could an authentic specimen associated therewith be registered also? Much, therefore, as we admire the object of the new organisation in question, we greatly fear that its main object can never be attained, and that it will find immense practical difficulty in getting the requisite regulations accepted by the trade, whose object it is to effect the freest possible circulation of the plants they deal in without creating an atmosphere of doubt and distrust, which strict legal regulations, affecting not only the seller but also necessarily the buyer, would create. We foresee, too, endless complications. Take the case of a protected chrysanthemum, which is distributed far and wide. Presently, if, as is the habit of the plant, it sports again in fresh hands, what would be the priority man's rights over the new progeny? And supposing these lapse so far as that is concerned, what will happen if some of the sports revert to his protected form, and are found out by him? Will the then owner be liable to prosecution? Truly, these be hard questions to answer.



MR. A. BASILE.

Mr. A. Basile, head gardener at Woburn Park, Weybridge, is well known as an tremely capable grower of fruit and vegetables, and of sweet peas, but it must be acknowledged that, though he is best known for his successes with these objects, Mr. Basile is one of the best general practitioners we have. He is a Belgian, and his first lessons in gardening he had from his father, who, for forty years, was head gardener to the Burgomaster of Tirlemont, in the province of Brabant. At fourteen years of age Mr. Basile became a pupil of M. H. Mellet, one of the most celebrated of Belgian horticulturists; here he remained five years, and during that period took his diploma at the Government School of Horticulture at Vilvorde. When twenty years of age he took up his first appointment as gardener at Rebec, Rognon, and a year later was offered, and accepted, the post of head gardener at Jette St. Pierre, near Brussels, where he stayed for five years. Following this came a period of six years as chief gardener in the Agricultural School belonging to the Josephite Fathers, at Grammont, in Flanders. It is thirty years since Mr. Basile first came to England, to take charge of the gardens and grounds at Woburn Park, then recently purchased from Lord Petre by the Josephite Fathers, and opened as a secondary college for the education of boys. Mr. Basile has enlarged the kitchen garden until it is now over three and a-half acres

in extent. He has planted thousands of ornamental trees and shrubs in the gardens and grounds, and seen many of the trees grow to considerable size. He has also planted many hundreds of fruit trees, and grows seventy-four varieties of pears, chiefly as pyramids and single cordons, and forty-six varieties of apples, in bush and standard form. Two large herbaceous borders and twenty-six large flower beds claim attention, in addition to the routine work of a large place. Mr. Basile has to his credit a record of over eight hundred prizes, chiefly for fruits and vegetables, including four silver cups and twenty-eight medals, among the latter being the Champion Gold Medal won at the Crystal Palace in 1899. Mr. Basile is always ready to give others the benefit of his wide knowledge and experience, but he is so modest that few know him except by reputation. The Rev. T. L. McMurdie, the present president of the college at Woburn Park, is himself a keen amateur gardener, and takes a close interest in Mr. Basile's work, and at all times is delighted to show his friends and visitors round this interesting place.

Cottage Gardens in Munster.—About three years ago Sir Bertram C. A. Windle, President of University College, Cork, conceived the idea of increasing the beauty of cottage gardens throughout Munster by the distribution of plants and seeds to labourers and cottagers. Large numbers of plants, etc., were distributed from the College Gardens, and others were contributed by Sir Bertram's friends. During the first year no fewer than 400 parcels were distributed, and altogether nearly 2,000 packages, each containing a dozen plants and a packet of seeds, have been sent out, with the result that interest has been created, enthusiasm excited, and the cottage gardens of the province greatly beautified. Sir Bertram is at present asking for surplus herbaceous plants, etc., so that larger distributions may be made in the near future.

Protection of Wild Birds.—Lovers of wild birds will be glad to learn that a committee has been appointed by the Home Secretary to consider whether any amendments are desirable in the Wild Birds' Protection Act, and whether improvements in the administration of the Act are necessary. The Committee is composed of Lord Lucas, Messrs. Frank Elliott, E. G. B. Meade-Waldo, W. R. Ogilvie Grant, and Hugh S. Gladstone, F.Z.S., with the Hon. E .S. Montagu, M.P., as chairman, and Mr. H. R. Scott, of the Home Office, as secretary, to whom all communications concerning the enquiry should be made.

The French Horticultural Society of London.—The annual Bulletin of this society has just appeared, and contains the usual record of the past year's work. Our old friend, Mr. George Schneider, is to be warmly congratulated on the progress the society still continues to make, and we hope he may be long spared to carry on the beneficent work he inaugurated so many years ago on behalf of his young fellow countrymen. The Bulletin this year contains 180 pages of text. For frontispiece there is a good portrait of Mr. Rudolph Barr, who took the chair at the last annual dinner. The usual literary matter is given, such as the rules, library catalogue, list of members, accounts, reports of monthly meetings, and of the annual dinner. There are also a number of papers read by the members on various subjects connected with horticulture. We note some on Kew Gardens, English cucumber culture, Guernsey horticulture, the Royal International Show of 1912, at Chelsea, a visit to Messrs. J. Carter and Co.'s at Raynes Park, S.W.

"Amateur Gardening" Christmas Number for 1913 lacks nothing in beauty or interest when compared with similar issues in previous years. The outstanding features are the delightful illustrations in colour, representing roses and garden scenes, and all reproduced from colour photographs. There are seventeen of these, and they alone are worth the 6d. charged for an issue which contains about two dozen other illustrations, and is full of information interestingly given. "Flowers of Magic," "Flowers of Romance," "Garden Herbs," "A Flame in Flowers," "In a Winter Garden," and "About Curious Pods," are a few of the principal articles in an issue that does credit alike to the Editorial staff, the Printers, and the Publishers. As such a splendid sixpennyworth is sure to sell well, readers desiring copies should promptly send their orders to the Publisher, 148 and 149, Aldersgate Street, E.C.

Sheen Common in Danger.—A proposal is on foot to convert Sheen Common into a sports ground. This little common, near Richmond, in Surrey, is a beautiful bit of wild nature, and to cut down trees and undergrowth, and lay out tennis courts, bowling greens, etc., would spoil it for ever. There is plenty of land available for sports in the neighbourhood, and so, naturally, many residents are opposing the loan of £800 proposed for the purpose of transforming the common. Every effort should be made to preserve, not convert, such a charming bit of wild country as Sheen Common.

The National Hardy Plant Society.—The annual meeting of this society will be held at the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, S.W., on Tuesday, December 9, 1913, at 4 p.m. The report and balance-sheet will be presented, officers for the ensuing year elected, and propositions brought forward affecting the policy and future working of the society. It is felt that progress has not been so rapid as it should have been, and the committee is therefore anxious to devise a plan of action that shall enable the society more fully to justify its existence, and accomplish its mission in the horticultural world.

A Plant Collector for the Royal Horticultural Society.—On many occasions a hope has been expressed that, when funds would permit, the Royal Horticultural Society should once more send out a qualified collector to some unexplored country for the purpose of adding to our store of useful garden plants. This subject, discussed somewhat freely in the pages of a contemporary, has drawn a letter from the Rev. W. Wilks, in which he writes that the "proposal for a collector is only one out of an almost innumerable number of suggestions for spending money which are constantly being brought before the Council, and they find a real difficulty in discriminating as to their relative merits."

Retirement of Mr. James Forbes.—Mr. James Forbes, head gardener at Overtoun, Dumbarton, for over 40 years, has just retired from active service, and is now resident at Milngavie. He served under three proprietors—Mr. James White, his son, Lord Overtoun, and the present proprietor. Both in Mr. White's and Lord Overtoun's time extensive alterations were made in the gardens and grounds, and these were all carried out under Mr. Forbes' direction. Mr. Forbes, who is one of the leading horticulturists in Scotland, is a native of Kincardineshire, and began his gardening career at Fasque, at that time the property of Sir John Gladstone, brother of the late Mr. W. E. Gladstone. His first head charge was at Beechwood, Partick, where he remained till he was appointed to Overtoun. Mr. Forbes has the unique distinction of having visited both the great International Horticultural Exhibitions in London, in 1866 and 1912. He is a member of all the leading horticultural societies north of the Tweed, and he has been a member of the Royal Scottish Arboricultural Society for a considerable number of years. His many friends and acquaintances will heartily join in the wish that he may be long spared to enjoy his well-earned retirement.

The Gold Hogg Memorial Medal is a rare award, and has only been granted on two occasions. About two years ago, this medal, which commemorates the late Dr. Hogg, a famous pomologist and writer, was awarded to the Agent-General of British Columbia for a superb display of fruit, staged in the Royal Horticultural Hall, Westminster. On Tuesday last the second gold medal was awarded by the Royal Horticultural Society to the Hon. Vicary Gibbs for a splendid lot of fruit, finely grown and finely exhibited by Mr. Edwin Beckett, V.M.H., the well-known gardener at Aldenham House, Aldenham, Herts.

Royal Gardeners' Orphan Fund Election.—Our readers should bear in mind that all nominations for the election of the Royal Gardeners' Orphan Fund must reach the Secretary, Mr. Brian Wynne, 19, Bedford Chambers, Covent Garden, W.C., on or before December 16, otherwise candidates will not be eligible for election on February 6, 1914, when the annual general meeting takes place at Simpson's, 100, Strand, W.C.

A Huge Chrysanthemum is reported from America. It is a specimen seven feet high and sixteen feet in diameter, and carried two thousand blooms. The name of the variety does not appear, but we learn that the plant was grown in the gardens of Mr. Samuel Untermeyer, a New York lawyer, and it has been on exhibition at the New York Museum of Natural History.

The Kew Seed List.—Each year the Kew authorities issue a "List of Seeds of Hardy Herbaceous Plants and of Trees and Shrubs," and the 1914 edition is before us. The names of available kinds fill twenty pages, and represent a very wide range of hardy plants. These seeds, mostly ripened at Kew, are available only for exchange with Botanic Gardens, and with regular correspondents of Kew.

Improvement of the Victoria Tower Gardens.—Everyone knows the great Victoria Tower of the Houses of Parliament, Westminster, either through personal observation, or by means of illustrations, but comparatively few know the Victoria Tower Gardens close to the House of Lords. A number of slums and wharves have been cleared away recently, and the site presented to the Office of Works by the London County Council; this means the addition of a piece of land, 300 yards long, to the Victoria Tower Gardens. Already the work of laying-out this new area and planting it with trees and shrubs is in progress, and when planting and railings have been completed the gardens will form a delightful open space in a position where it

is much needed. In the older portion of the gardens, Rodin's famous group, "The Burghers of Calais," will be set up, and the Victoria Tower will form a background for it. The unveiling of the group is expected to take place in March, 1914.

Takings at Norwich Chrysanthemum Show.—We learn that the total receipts at the Norwich Chrysanthemum Show were £220 17s. 5d., as against £259 0s. 5d. in 1912, the falling-off being attributable to the incessant rain on Friday, November 21. As the Norwich Horticultural Society depends largely upon its takings at the November show to "pay the way," this loss is a serious one, and unless the garden and estate owners of Norfolk and Norwich swell the list of annual subscribers, there will be considerable difficulty in holding spring and summer shows in the future.

Scenery and Disfiguring Advertisements. — Mr. Richardson Evans, chairman of the Committee of the Scapa Society, reminds us of the power which local authorities possess under the Advertisements Regulation Act, 1907. In many districts magistrates have lately directed the removal of advertisements which disfigure the natural beauty of a landscape or views from public parks and promenades. He points out that next year, in Westmorland, the power of general prohibition will become effective, and as the term of five years' grace allowed by the Act to existing advertisements expires in other districts, for which the local authorities have been wise enough to make by-laws, the eyesores will completely disappear. Pressure should be brought to bear on local authorities to avail themselves of the provisions of the Act. Unfortunately the statute of 1907 gave no adequate power of protecting the dignity of city "prospects" or the quiet beauty of villages and small towns. Mr. Evans hopes the Bill prepared by the Scapa Society, of which Captain Murray is in charge, will become law next Session, and that means will then exist for satisfying all the reasonable requirements of local opinion.

Violet Kaiser Wilhelm. — Mr. Thos. Johnson, of Motcombe House Gardens, Shaftesbury, sent us about three dozen splendid blooms of the deliciously fragrant violet named Kaiser Wilhelm. The stems were long and sturdy, and the flowers well over an inch broad, with rounded, violet-purple segments and a small white centre. Mr. Johnson tells us that he grows violets largely in frames, and we can certainly say that, if the blooms sent are a fair sample, he grows them exceptionally well.

Raspberry November Abundance.—The article on "Autumn-fruiting Raspberries," which appeared on page 827 of our issue of November 1, has inspired Mr. A. K. Turner, Orwell Park Gardens, Ipswich, to send us the followed particulars, together with some fine clusters of luscious fruits of November Abundance raspberry: "The autumn-fruiting raspverry November Abundance does remarkably well here on the East Coast, but I admit ours is a sheltered garden. We have been gathering first-class fruits of this variety for over three weeks, and hope to continue for another week, weather permitting. I find this an indispensable variety to follow October Red and October Yellow, as it carries us well into November, and provides excellent fruit for breakfast dessert. I find these late raspberries enjoy a rich and fairly heavy loam, and to procure the very best results a new row should be planted every spring, to last for three years. Plenty of young plants are always procurable from the older rows, and a new row every year pays for the trouble it gives. I noticed, two years ago, that the variety October Yellow failed to produce many fruits, although treated precisely as the other autumn varieties, which bore well. Having made a note of it, I cut back some of them half-way last spring, instead of almost to the ground; they produced lateral growths, and have fruited on the laterals splendidly this year. I am wondering if this is an exception to the rule, and whether anyone else has tried the plan?"

Seeds which are Like Insects. —The Royal Horticultural Society's Scientific Committee recently had before it some curious seeds, sent up from the Orchid Committee, to whom they had been sent as insects which infested an orchid house, without, however, any damage being traceable to them. They were considered to be the seeds of some plant, probably an oxalis, which had scattered them over the house, and bore a distant resemblance to minute beetles, minus legs.

Serious Damage by Insects. —According to the "Excelsior," the damage caused by insects in the vineyards in Bordeaux district amounts to £1,600,000 annually.

NEW PLANTS AND FLOWERS.

PRIMULA MALACOIDES PLENA.

This is a delightfully elegant plant with double flowers, but the dainty blossoms are not so heavy or so much doubled as to spoil the grace so evident in the type. The colour varies a little, as in the case of the single form, but is usually of a soft rosy-lilac or pale mauve. Evidently these flowers last longer than the single ones. A.M., R.H.S., December 2. Messrs. Bees, Lim., Liverpool.

CATTLEYA MAGGIE RAPHAEL, THE DELL VARIETY.

This glorious variety of an increasingly popular hybrid is one of the finest of catt.

PRIMULA MALACOIDES PLENA.

A beautiful double-flowered form of a popular plant; the blossoms are dainty, and of a pale rosy-lilac shade. A.M., R.H.S., December 2. Messrs. Bees, Lim., Liverpool.

leyas seen this year. The specimen shown was very finely grown, and had a spike of four superb blooms. The pure white sepals and petals formed a striking and contrasting background for the large, purple-apexed lip, with its wide area of gold shading and veining running into the throat, and a pale and wavy margin all round, that was almost white. F.C.C., R.H.S., December 2. Baron Bruno Schroder (gardener, Mr. Shill), The Dell, Egham.

CHRYSANTHEMUMS.

Commodore.—A superb single chrysanthemum with all the beauty of form and fine substance which characterises that splendid variety Mensa. It may be said to be a brilliant crimson-red counterpart of the latter,

but we understand it is not a sport, but a seedling, raised by Mr. Tom Page, of Hampton. A.M., R.H.S., December 2. Mr. Thos. Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, Addlestone.

Cardinal.—This brilliant single variety has flowers of medium size, and of the richest scarlet-crimson imaginable, with a large yellow disc, surrounded by a very narrow yellow zone. About 2½ft. high, and free-flowering, it should become popular, especially as the flowers show up well under artificial light. A.M., R.H.S., December 2. Messrs. Jas. Veitch and Sons, Chelsea.

Mauve Beauty.—This is a very distinct, closely incurving Japanese variety of good size and fine substance. It has broad, pointed florets, a fine stem, and ample foliage. The lower florets are of deeper, rosier hue than the bulk of the flower. It appears to be a variety that would travel well, and it grows about 5ft. high. II., 2, b.; Commendation, N.C.S., November 24. Messrs. W. Wells and Co., Merstham.

Bertha Lachaux.—A charming decorative Japanese variety with graceful, narrow, and reflexing, semi-drooping florets of a lovely shade of mauve pink. The blooms are of fair size, borne on slender, but stiff, stems, furnished with medium-sized, deep green leaves. A beautiful variety for late decorations. II., 1, b.; F.C.C., N.C.S., November 24. Messrs. W. Wells and Co., Merstham.

AGATHIS VITIENSIS.

An interesting conifer, which is endemic in mixed forests in the Fiji Archipelago, where it is known as the Dakua, and is abundant in the islands of Vanua and Viti Levu. It also occurs, but less plentifully, in the Islands of Ovalau and Kaduvu. In Ovalau some remarkably fine specimens have been found, one with a trunk having a diameter of five feet, and some with a height ranging from eighty to one hundred feet, with clear stems up to sixty feet. The bark is described as peeling off, in much the same manner as that of the Australian gum-trees, and the wood, which serves much the same purposes as deal, is used by the Fijians for house floors and for masts, booms, and spars. The tree exudes a gum which, in the interior of the larger islands, has been used for burning in place of cocoa-nut oil. The species has been grown at Kew since 1881, the first sixteen years in the tropical palm house, and since then in the Mexican house, and the tree has now attained a height of twenty-five feet. In 1911, it produced female cones, which are globose, 3¾ inches long, 3½ inches wide, and of a bright green colour. Bot. Mag., t. 8,512.

ROSA FOLIOLOSA.

A distinct and attractive species, indigenous to North America, which has been described as the South-Western Prairie Rose, owing to its apparent restriction to the prairie region of Arkansas, Northern and Central Texas, and the Indian territory. This special has a dwarf habit and running root-stocks, and bears fragrant single flowers about 1½in. in diameter, and of a rich carmine colour. It was originally discovered by Nuttall during his visit to Arkansas in 1818-20, but was not published by Torrey and Gray until twenty years later, and after it had been met with in Texas by Berlandier and others. It is stated that, according to a manuscript list of the trees and shrubs in cultivation at Kew, prepared in 1880 by Sir Joseph Hooker, it was then in the Kew collection, but as late as 1890 it was considered a rare plant at Harvard, Massachusetts. The plate published in the "Botanical Magazine" was prepared from a flowering spray produced by a plant in Canon Ellacombe's garden at Bitton, where it blooms as late as the end of August. As a garden rose the species possess much value, for the elegant single flowers are attractive in colour, and it is readily increased by division. It appears to be well deserving the attention of hybridists who are anxious of breaking away from conventional lines. Bot. Mag., t. 8,513.

BLACK CURRANT MITE.

Having read your articles on the above subject, and being very interested in the matter, it occurred to me that readers of THE GARDENERS' MAGAZINE might like to know that I have adopted Mr. A. H. Pearson's method of trying to eradicate Black Currant Mite. I wrote to Mr. Pearson in the early spring, asking his advice as a large grower of black currants, and he very kindly sent me full particulars (as set forth by him in your columns) of how to set to work to try and remove the pest. As I had some very fine Boskoop Giant black currant trees, I was anxious not to grub up or destroy them, or yet cut them down to the ground, so as to make them break up afresh, and thus try to eradicate the mite. By following the Pearson system I now feel confident I may, in a season or two, clear my trees of the pest. Already they look more promising, and I propose in the early spring of 1914 to again follow out his directions.

There is not the least doubt that if anyone wishes to keep either his apples, pears, currants, gooseberries, etc., clean, and have fruit of good appearance, he must spray the trees every season. To carry out the work for one season only is a waste of time and money. I know we have great difficulties to contend with, as very often our neighbours cannot see the necessity of spraying. They seem to think that because our forefathers never sprayed their fruit trees we need not do so now. Fruit of a certain class is easily obtained, and it realises a certain price on the open market, but I know for a fact that my fruit, from my sprayed trees, will realise a more satisfactory figure than theirs. Why is this? One need not look very far to find the reason. Comparing my fruit with theirs, it has not only a better appearance, but is larger in size. The extra value therefore pays for the expenditure of spraying. My advice to all growers of fruit is to spray, both winter and summer.

If the Board of Agriculture would take up this subject in the same energetic way as it has American gooseberry mildew, it would be a very good thing for the country. The Board should enforce spraying. Meanwhile, let us all try and produce as good fruit as our foreign neighbours, for unless we take care we shall be left behind—simply because we will not put enthusiasm and keenness into the work, but leave others to do the pushing.

E. J. WOOTTEN

Fairoak, Eastleigh, Hants.

In recent issues of your valued paper I have read a good deal about Black Currant Mite, its prevention and cure. While I cannot say anything for or against Mr. Pearson's remedy, not having put it to a proper test, I nevertheless mean to follow his advice from this season onwards.

I think, however, that those who wish to grow this most useful and excellent fruit satisfactorily had better make up their minds to grub up their old trees every sixth year at the latest, as I am almost convinced that without proper treatment the trees will not keep clean longer than the period mentioned. It might, perhaps, be wiser in the first instance, when, say, four acres are to be planted with black currants, to commence by planting two acres only, and fill the remaining space three years after. The grower would then always have a good stock carrying a full crop, and younger plants to take their place when grubbed up.

My experience is as follows: Seven or eight years ago, I planted a batch of Boskoop Giant, which, at the time, had the reputation of being exempt from the mite; and this proved correct until last winter, when I found a fair number of big buds all over my trees, and these I carefully removed myself and burned, afterwards spraying the trees as recommended by Mr. Pearson. Doubtless, I was too late in removing the big buds, as this autumn, after the leaves had fallen, I noticed big buds were infinitely more numerous, and so I decided to uproot all the infested trees and burn them.

Since then I have planted Seabrook's Black, which, up till now, has a clean record.

While, therefore, I am quite a believer in Mr. Pearson's remedy, and intend to follow the instructions given by him in your columns. I am convinced that without treatment the trees have only a short clean life, and consider that all growers have to face the expense of buying fresh stock every few years if they have not space to grow fresh stock from healthy cuttings.

Only last season I planted a few fresh clean plants of Boskoop Giant close to the mite-infested older trees, and, to prove what I have said, these young ones have not a single big bud on them.

R. MORTON.

Grange Dene, Woodside Park, N.

PÆONY-FLOWERED DAHLIAS.

I see, on page 885, a correspondent states he cannot understand how it is that the pæony-flowered dahlia has become so popular; in fact, it appears to strike him as a mystery how this particular section of the dahlia has forced its way into the front rank of late summer and autumn-flowering plants, in place of the popular cactus forms. Now, I fail to see anything mysterious about the matter, for the pæony-flowered varieties were launched on the dahlia world just at the time the cactus varieties were being decried because of their bad stems and lack of decorative effect in the garden.

The new-comers did not receive a hearty welcome; in fact, they were abused almost on all sides, except by the people who had seen them in the garden, which is their proper place. They had no claims as a florists' flower, neither have they now; and I take it they are merely exhibited to draw the attention of the public to their claims as autumn-flowering plants, and I trust the day will be far distant when they are drawn into the hard and fast regulations of an old-time florists' flower.

Your correspondent seems to require a standard of perfection drawn up, as in the case of the show dahlias. At the same time he quite overlooks the fact that no such standard has ever been drawn up in the case of the cactus varieties. It was the hard and fast rules as to form which killed the popularity of the double dahlia as a garden flower, and anything approaching strict formality will act in a like manner in the case of the section under notice. Your correspondent will have no difficulty in making a selection of varieties with clearly defined "eyes," or those possessing a centre of short florets; he may describe them as confused, or he may regard them as charming, according to his taste. In either case, I trust we shall avoid the florists' rule.

I take it the aim of the raiser should be to obtain a pleasing flower that is freely produced, and, above all, with a good stiff stem that carries it well above the foliage, so that when the blooms are gathered for decorative purposes they remain erect, and do not "flop" all round the hand of the gatherer. After all, it is a matter of time, and that a short one, too, when the varieties with weak stems will be eliminated. I noticed that the Joint Committee of the Royal Horticultural Society and the National Dahlia Society, during the season just passed, would not look at a pæony-flowered variety that was supported by wires, or that did not possess a good stiff stem. I trust it will not be long before the cactus varieties come under the same unwritten law, for such holds good now, so far as the Garden Cactus dahlia is concerned.

Under no circumstances should the pæony-flowered dahlia be restricted to any particular form, for we have already three or four types, each good in its particular way, and it is quite a matter of opinion as to which type is best. The pæony-flowered varieties were never intended to be exhibition flowers. Their proper place is in the garden, where they have already asserted their right to be placed as decorative plants.

R.

THE HORSE CHESTNUTS.

Exactly why two such very distinct trees as the Æsculus and Castanea should both bear the popular name of Chestnut is not very clear. Admittedly, there is some resemblance in the spiny husks and shining brown fruit or seeds, but here the likeness ends. Not only do the Horse Chestnut and the Sweet Chestnut belong to different genera, but they are members of widely distinct natural orders, Æsculus to Sapindaceæ and Castanea to Cupuliferæ.

Æsculus.

Among large ornamental-flowering trees growing in our pleasure grounds and parks first place must be given to the Common Horse Chestnut. As a specimen tree, several trees planted to form an imposing mass, and as an avenue tree, when in flower the Common Horse Chestnut is unequalled. While the ornamental character of the tree is such a strong point, quite the opposite is the case if it is considered for close woodland and coppice planting. The distinct, wide-spreading habit of the branches renders the tree worthless for close planting. The timber is not of much commercial value, while for firewood its worth is, perhaps, explained by saying that our men here seldom carry it home, preferring any other wood of the larger timber trees, except that of the Sweet Chestnut.

Ten species of æsculus are in cultivation, half of which are natives of North America, four natives of Asia, and one a European species. As well shown in the illustration, some species have spiny fruits, while those of other species are quite smooth. A second peculiarity is that several species have four and others five petals. These characters were formerly used as a generic distinction, those with spiny fruits and five petals being known as Æsculs, or Horse Chestnuts, and the species with four petals and smooth fruits as Pavia, or Buckeyes.

The cultivation of the Horse Chestnuts presents no difficulties. The trees, even when a fair size, transplant successfully. All are perfectly hardy, with the possible exception of the Asiatic species, which, though they occur at fairly high elevations in a wild state, should, except in the south and west, be planted in fairly sheltered positions. Seeds form the best and a ready means of increasing stock. These should be sown as soon as ripe, or, at any rate, be kept during the winter in damp sand, for if kept dry they soon lose their vitality. The hybrids and the double variety are increased by grafting or budding, the Horse Chestnuts on stocks of Æsculus Hippocastanum and the Pavias on Æ. flava or Æ. glabra. It is important when grafting or budding to use the wood at the base of the young shoots where the eyes or buds are small.

With regard to soil, a rich loam, moist rather than dry, is the most suitable, but it must be a very bad soil if the Common Horse Chestnut fails in it. On the other hand, if available, as the trees are gross feeders, mulches of manure prove very beneficial, particularly on light soils.

Æ. californica.

Commonly referred to as the Californian Buck-eye, this species grows wild on the banks of the Upper Sacramento River, California, and the western slopes of the Sierra Nevada mountains. Though first introduced as long ago as 1855 by the Messrs. Veitch, of Exeter, where it first flowered three years later, the Californian Buckeye is but very little known. It forms a large shrub or very spreading tree, the diameter of the branches being almost invariably greater than the height. A tree at Kew is 15ft. high, and 20ft. through. The tallest specimen recorded in this country is in the Isle of Wight, where it is said to be 20ft. high.

The leaves are noteworthy as being the smallest of the family, 3in. to 5in. long, generally in fives. The flowers are white, ¾in. in diameter, closely disposed on a compact raceme some 6in. to 7in. long, with conspicuous orange-coloured anthers. The flowers are fragrant. The fruits, as shown in the illustration, are spineless, brown in colour, in shape resembling a small pear, 2in. to 3in. long. A most important trait in the character of this buck-eye is the fact that the flowering season lasts for two months, a succession of flowers opening from June to August. Æsculus californica is useful to plant as a lawn specimen and in the shrubbery. Its value for the former purpose may be seen at a glance on referring to the illustration of a tree, growing at Kew, in the Gardeners' Magazine of 1912, page 577.

The fact that most of the trees of A. californica in this country are growing in gardens of the south and west suggests that in other parts of the country the most sheltered positions available should be chosen.

[Photo: C. P. Raffill.

HORSE CHESTNUT FRUITS.

1, Æsculus Pavia; 2, Æ. carnea; 3, Æ. californica; 4, Æ. flava; 5, Æ. glabra; 6, indica; 7, Spineless hybrid from Æ. Hippocastanum; 8, Æ. Hippocastanum.

Æ. carnea.

The red or scarlet Horse Chestnut is reputed to be a hybrid between the Common

Horse Chestnut and Æ. Pavia. Circumstances, however, at one time seemed to point to some doubt about this, as seedlings have been raised which came true; but against this, another raiser reports seedlings resembling the Common Horse Chestnut. Whatever its origin, no one can dispute the value of Æ. carnea as an attractive flowering tree. The average height of the mature tree is about 30ft., with spreading branches, generally forming a rather formal, round-headed tree. At Barton, in Suffolk, an unusually tall specimen is recorded 50ft. in height.

Æ. carnea is, perhaps, the best of all flowering trees of moderate size for planting in town and suburban gardens, public parks and open spaces, the ordinary smoky atmosphere having little effect on its beautiful flowers.

The leaves of the Red Horse Chestnut are not quite so large as, but much darker green than, those of Æ. Hippocastanum. The inflorescence is 6in. to 10in. long with rosy-red flowers; each petal is blotched at first with orange-yellow, but this disappears with age. The fruits are slightly spiny. Even more showy than A. carnea is the variety Brioti, which has richer red flowers. It is a seedling raised from Æ. carnea, in France, about the middle of the last century. There are also two varieties with variegated foliage—aureo-marginata and folius marginatis.

Æ. Hippocastanum.

The Common Horse Chestnut is a native of Northern Greece and Albania. It has been so freely planted, and trees form such beautiful objects in our pleasure grounds and parks, that everyone must be familiar with its attractive character. In habit the Horse Chestnut forms a very large, round-headed tree 50 to 70ft., occasionally reaching 100ft., in height, and, owing to the wide-spreading nature of the branches, it is usually as much in diameter. No better example of the value of the tree for avenue planting could be wished for than the famous Chestnut Avenue in Bushey Park. As a specimen tree for the pleasure grounds, or several together forming a large group in the park, the Common Horse Chestnut is unrivalled.

In public parks, open spaces and as a street tree it is unfortunate the fruits are so attractive when ripening that it is difficult to prevent boys throwing sticks and stones to knock down the nuts. To obviate this difficulty in public places the double variety, flore pleno, may be planted. This does not produce nuts, is as free in growth as the type on which it is budded or grafted, and the flowers last longer on the trees.

The Horse Chestnut thrives better than most large-growing trees in the smoky atmosphere of large towns. When the flowers first open a yellow patch of colour is present at the base of the white flowers, which, with age, changes to red. It is worth noticing that, though each upright panicle produces quantities of flowers, comparatively few spiny fruits mature on each. Close examination reveals the fact that many of the flowers are incomplete, which is evidently Nature's method of preventing the trees from being over-taxed with heavy crops of fruits. In addition to the double one, half a dozen or more varieties have been given distinctive names, which, as a rule describe how they differ in foliage or growth from the type; e.g., crispum, folius aureis variegatis, laciniata, digitata, and pyramidalis—the latter an upright-growing form, deserving of attention as a street tree.

A. OSBORN.

(To be continued.)

AUTUMN AND WINTER-FLOWERING HEATHS.

At all seasons of the year some greenhouse members of the great Heath family may be had in bloom, but collections are rarely to be met with in gardens. Time was, however, when every garden of any pretensions whatever had a structure devoted to the culture of heaths and allied plants. Nowadays a few kinds are still popular, and are grown in large quantities by nurserymen who make a speciality of their culture.

Of autumn and winter-blooming kinds the first to flower is Erica gracilis, a neat, bushy little plant, with tiny, rosy-purple flowers borne in great profusion. The colour of the blossoms is, to a certain extent, influenced by the amount of exposure the plants have undergone; those that are left out in the sun and air longest being the deepest coloured. Apart from these considerations, there are some well-marked varieties; namely, nivalis, in which the flowers are usually white but sometimes tinged with pink; rosea, with blossoms of a clear rose tint and scarcely any trace of purple; and vernalis, much later in blooming than the others, and more sturdy in habit. Erica gracilis and its forms are more easily grown than most greenhouse heaths.

A dwarfer kind, somewhat in the same style but rather later in blooming, and with white flowers, is Erica caffra.

The showiest heath that can be had in bloom at Christmas is Erica hyemalis. Of this, delightful little bushes, laden with blossoms, may be seen in the florists' shops of London. These heaths are grown by the few nurserymen who still make a speciality of hard-wooded plants. The flowers, with their pretty rose and white colouring, are borne in great profusion for some distance along the erect shoots. There is a variety, superba, of a richer colour than the type, and also the pure white form, alba. This last is remarkably chaste and very generally admired.

An old species that has come a good deal to the front within recent years is Erica melanthera. It may be grown into goodly specimens, but is usually met with as bushy plants in pots five or six inches in diameter. The tiny blossoms are of a distinct mauve shade, with conspicuous blackish anthers. The flowers have a slight but pleasing perfume.

Though Erica hyemalis is so generally grown its early history seems to be unknown, a remark which also applies to the somewhat allied Erica Wilmoreana, which comes into bloom early in the New Year. After this come many others, notably, Erica persoluta and E. persoluta alba, E. colorans, E. candidissima, E. Spenceriana, etc. These heaths are usually grown in pots five or six inches in diameter, but another system has been adopted lately, and little, flowering examples in tiny pots, and full of bloom, form a prominent feature of many florists' shops, and, what is more, they meet with a ready sale.

When the different heaths are employed for indoor decoration particular care must be taken that they are not allowed to become dry, otherwise they will quickly suffer. The ball of earth contains, as a rule, a dense mass of roots, and therefore quickly dries. One is often consulted as to the treatment that should be given to these greenhouse heaths after flowering. The best way is to cut them back moderately hard, and, as soon as the young growths have started, then repot in some good sandy peat. The soil must be pressed down very firmly. Grown for the first part of the season in the greenhouse they may, as the season advances, be stood out of doors to ripen their growth, and so ensure the formation of flower buds. Careful watering is at that time particularly necessary.

S. W.

TWELVE BEST PERPETUAL CARNATIONS FOR PRIVATE GARDENS.

It is not an easy matter to select twelve varieties of perpetual-flowering carnations and say that such a set is the best for private gardens, but after considerable experience and due consideration I record the following as the best dozen for amateurs' greenhouses—or, indeed, I might say they are the best twelve in cultivation for every grower:

Triumph is much the best crimson variety, as it is easily grown, makes an extra good plant, and carries large flowers. It is very free flowering, the stems are always stiff, and the blooms keep well. I consider Triumph the best seedling that has yet been raised in England.

Scarlet Glow is, so far, the best true scarlet, being an "easy doer" and free bloomer. The medium-sized flowers are borne on very stiff stems, and growth is clean and healthy.

In my estimation White Wonder is the best white, because it is a rather quicker grower than White Perfection, and gives more flowers of the largest size. Either this or White Perfection should be in every collection.

Lady Northcliffe, a lovely salmon-pink flower for dinner-table or other indoor decoration, is unequalled in its class, and I strongly recommend everyone to grow it.

May Day, another lovely pink variety, slightly paler than Lady Northcliffe, is a true amateur's carnation, because it is the freest flowering variety I have ever grown.

Washington stands at the head of the rose-pink section, and it is a tip-top variety in every respect, being identical in every way, except colour, with Enchantress.

In Mrs. C. W. Ward we have a very fine variety of the old Lawson colour. It is not quite so free flowering as some varieties, but every bloom is good, and it is one of the very best growers I have ever handled.

Enchantress is still the best blush-pink carnation, and, though some experts regard it as played out, I have not found its superior yet. It has been very fine this autumn everywhere I have seen it, and so I strongly recommend everyone to stick to Enchantress a little longer.

Mrs. A. F. Dutton is grand; it is a lovely apple-blossom pink variety with very large flowers, and an extra good grower. It varies a little in colour, but, nevertheless, is the best pink carnation I have ever grown.

The stock of Salmon Enchantress, sent out by the Messrs. Allwood Brothers, is easily the best of its colour. I thought very little of the variety when I saw it at the exhibitions last year, but it has easily surpassed all my expectations and hopes.

Mikado remains the best mauve carnation for amateurs, and although Fairmount gives a larger flower it is not so free with me. Geisha I find disappointing, and so still regard Mikado as the best of its colour.

Sunstar is a very near approach to a yellow carnation, and but for a few pink markings would be a pure yellow. It is the best keeper I know, for I have kept blooms of it three weeks; therefore I strongly recommend everyone to try it.

A. E. USHER.

Ranston Gardens, Blandford.

FLORAL DECORATIONS FOR THE DINNER TABLE.

In most private establishments the decoration of the dinner-table is an important matter on special occasions, and necessitates the cultivation of a variety of flowers. The style of decoration that finds most favour in a gentleman's residence is very different from the displays so frequently seen at flower shows. As a general rule table decorations possess a great similarity, and so it is often desirable to break away from conventional lines as far as is consistent with good taste. Employers invariably appreciate a novel arrangement and a change in the usual mode of decoration.

It is customary to keep the decorations fairly low, as diners prefer to see one another across the table; but if some of the flowers are to be arranged on a higher level the vases used should be tall enough to admit of an uninterrupted view beneath them. When decorating a large table it is desirable to place an imposing arrangement in the centre, and in the case of a very long table a series of such displays is essential, while the intermediate spaces should be filled in with low vases.

Various receptacles are utilised for the flowers; and bowls and narrow vases are the best. As a rule the latter should be about seven inches high, and they may be of plain glass, silver, or silver-gilt, and the flowers must be chosen to give the best effect with whichever kind is used. A bright colour, like scarlet, is especially effective, but when it is used plain glass or silver vases are most suitable, and the latter are preferred. When silver-gilt vases are employed colours of a fairly soft shade will be found most pleasing.

The arrangement of flowers in bowls is a difficult matter without the assistance of some artificial means of support, and for this purpose small vases or test tubes packed lightly in the bowls with moss answer admirably, and are much better than the use of a wire framework. Lightness of arrangement is most essential, and it is important to have the blooms on different levels to heighten this effect. When dealing with flowers which have rather short stems it is necessary to wire some of them, and the green zinc tubes on long wires are a useful aid. Very frequently the foliage belonging to the flowers employed can be used, but when this is not possible Asparagus Sprengeri and maidenhair fern are suitable to associate with most indoor flowers.

A table decorated with one colour only is always effective, but mixed colours are often employed with excellent results. As a general rule it is not advisable to use more than three colours together, unless a selection of outdoor flowers and foliage is available, when a decorator with artistic tastes can blend a combination of colours in a pleasing and effective manner. If only two colours are used it is well to produce a direct contrast—such, for example, as red and white, or pale pink and mauve, which could be carried out either in carnations or sweet peas.

The way the vases are placed on the table is almost an art in itself, and it is astonishing how different is the effect produced according to the manner of the arrangement. Avoid straight lines and overcrowding, or the decorations will be deprived of their full beauty and charm. Whether flowers and foliage are used on the cloth or not is largely a matter of taste; in certain cases it is a decided improvement, but not in others. When tracery on the cloth is practised it is desirable to let it be quite informal in character, and it is better to use a very little rather than err on the side of extravagance.

Begonia Gloire de Lorraine and other winter-flowering begonias are especially suitable owing to their bright colour and free flowering habit. When these are used whole plants should be placed in silver cups, and their pots hidden with fresh moss. Calanthes are among the most glorious of winter-flowering subjects, and they make a really handsome table decoration, but should only be used when the table is of large size. Some good spikes of Asparagus Sprengeri should be intermixed with the flowers, and a little smilax placed on the cloth is an improvement. Tulips in variety form an effective decoration, and are improved if lily of the valley is used with them.

THE DOUBLE-FLOWERED HORSE CHESTNUT.
(Æsculus Hippocastanum flore-pleno.)

We find perpetual carnations extremely useful for table decorations during the winter and spring months. Tables decorated with blooms of one colour, or with mixed colours, are almost equally attractive, and no other flower meets with greater appreciation. A little carnation foliage should always be used with the flowers, together with any other greenery that is required. Some of the best single chrysanthemums are eminently suitable for table decorations, and so are several of the more showy decorative varieties. Salvias make a bright display and associate very well with Roman hyacinths or lily of the valley. Pelargoniums are popular with some, but unless they are very carefully arranged they are inclined to be stiff and heavy.

Poinsettias make a splendid table for Christmas time, but when they are cut plunge the stems in hot water to prevent bleeding. A little holly should be placed on the cloth, and besides using small sprays of it a novel plan is to take single leaves, place berries on the spines, and lay them on the table in an informal manner. Few people care to use foliage plants for the table now, but symmetrical flowering plants are a great help at times, and may be used on unimportant occasions.

A table decorated with coloured foliage in the autumn is invariably admired, as it is a departure from the usual style, and some of the colours rival the most brilliant flowers.

Batsford Park Gardens.

THE COTONEASTERS.

(Continued from page 884.)

As previously stated, the majority of the species are natives of the Himalaya and China, those from other countries being of little consequence so far as our gardens are concerned. There are, however, two or three European species, and one has been connected with the British flora. The genera most closely allied to cotoneaster are pyracantha and mespilus, and a few species have been included in mespilus by some botanists, while the plant often grown as C. augustifolia is now considered to be a pyracantha. A few species have also been included with cratægus. With one or two exceptions the species have been introduced within the last ninety years, the Himalayan kinds being brought to light during the second quarter of last century, when several botanical expeditions visited the mountains of Northern India, and the majority of the Chinese kinds are part of the spoils secured by Mr. E. H. Wilson between 1899 and the present date.

C. accuminata was one of the earliest kinds to appear from the Himalaya, the date of its introduction being given as about 1820. Growing from six to ten feet high, it is of erect habit, with ovate, deciduous leaves, varying from three-quarters of an inch to two inches in length, and covered with fine soft hairs. The small, pinkish flowers are borne several together from short, axillary growths. They are not very conspicuous, but are succeeded by scarlet fruits.

C. acutifolia, a native of Mongolia, is also represented by varieties in other parts of the Far East, notably villosula and pekinensis. The leaves of these two varieties vary considerably in size, those of the former being up to four inches in length and two inches in width, whilst those of the latter range from half-inch to one and a-half inches in length. In both cases the young wood and undersurface of the leaves is pubescent. The leaves of the type are ovate, about one and a-half inches long, and the fruits are large, oval, and bright red in colour.

C. adpressa forms a compact bush, scarcely a foot in height. Its frondose branches are clothed with small, ovate leaves, which bear some resemblance to those of the better-known C. horizontalis. The flowers are small, solitary, and sessile from the leaf axils, and they are followed by small red fruits. It is an excellent subject for planting on rockwork. A native of China, it was first grown in Europe by M. Vilmorin, at Les Barres, about fifteen years ago.

C. amœna is a new species, which was sent to Messrs Veitch from Western China early in the present century. An evergreen shrub, it has somewhat of the general habit of C. buxifolia, with similar-sized, but paler, leaves. The leaves are ovate, rarely more than half an inch long, the undersides, together with the shoots, being densely pubescent, the upper surface less so. The small, inconspicuous flowers are borne, a few together, in axillary clusters, and are succeeded by showy red fruits, which ripen in September.

C. baccillaris is one of the largest-growing of Himalayan species, for it sometimes attains a height of twenty feet or more, whilst it commonly grows twelve to fifteen feet high, with a wide spread. Its secondary branchlets have a peculiarly graceful poise, and they are clothed with dark green, ovate or oblong deciduous leaves, which vary from one and a-half to three inches in length. The small white flowers appear freely in flattened heads from the leaf axils, and are very effective when at their best. The fruits are dark purple, or almost black, and ripen in September. The variety affinis has purplish or reddish-purple fruits.

C. bullata is one of the most showy of the new Chinese kinds. Forming a bush four or five feet in height, it has ovate, wrinkled leaves, which are downy on the undersurface, and vary in size from one and a-half to three and a-half inches in length, and up to two inches in width. The flowers are small, and of little importance from a decorative standpoint, but they are succeeded by drooping panicles of scarlet fruits. There appears to be some reason for including this and C. moupinensis as the same species.

C. buxifolia.—This is a well-known evergreen species from the Himalaya. Growing at least ten feet high, it forms a large, wide-spreading bush, clothed with small, dark green, box-like leaves, showy white flowers in May, and small red fruits later in the year. It should be given a position where it can spread freely without interfering with other plants.

C. denticulata, an interesting species from Mexico, is probably not in cultivation in this country. The chief point of interest attaching to it is the dentate-margined leaves, the leaf margins in cotoneaster generally being entire.

C. Dielsiana is more familiar under the name of C. applanata, the name by which it was originally distributed in this country. It is one of Mr. E. H. Wilson's Chinese introductions, and is known as an elegant bush four to six feet high, with ovate deciduous leaves, often less than an inch in length, covered with grey felt on the undersides. The flowers are not very conspicuous, but they are succeeded by showy, bright red fruits, several often appearing together from each leaf axil.

C. divaricata has somewhat of the habit of C. horizontalis, but the growth is more vigorous, and leaves larger. A native of China, it forms a rather low, spreading bush, about two feet high, with ample leafage, small flowers, and red fruits. The leaves are about three-quarters of an inch long, and rather more than half an inch wide.

C. Francheti, a Chinese and Thibetian shrub, was introduced to France about eighteen years ago, seeds being received in 1895 by M. Maurice Ld de Vilmorin from Abbé Soulie, Thibet. Growing to a height of eight or ten feet, it is peculiar by reason of the young shoots and ovate leaves being covered by a dense mass of felty hairs. The flowers are borne in clusters from short, axillary shoots. They are not showy, but are followed by scarlet fruits, which, in the young stages, are also pubescent. C. frigida, a native of the Himalaya, is, perhaps, the most vigorous and most showy member of the family. Although often met with between twelve and eighteen feet high, it sometimes exceeds thirty feet in height, with a similar spread. The deciduous leaves are more or less oblong or obovate in outline, up to six inches long and two inches wide, pale green above, and greyish beneath, by reason of a dense pubescence. The white flowers appear in large axillary inflorescences in May, and are succeeded by bright red fruits, which last for a considerable time during autumn. Bunches of fruit are often from four to six inches in diameter. A form with orange-coloured fruits is known.

C. Harraviana is a new Chinese species, with slender branches, clothed with evergreen leaves from one and a-quarter to two inches in length, and up to one inch in width. The flowers are not very showy, but they are succeeded by red fruits.

C. Henryana is another of Mr. Wilson's Chinese introductions. Of loose habit, it grows five or six feet high, bearing lance-shaped or oblong leaves up to four and a-half inches long, with revolute margins. The leaf surface is light green and wrinkled, and the underside grey and hairy, with conspicuous veins. The white flowers are small, in axillary clusters, and are succeeded by small scarlet fruits. It appears to require a sunny position to furnish the best results.

C. horizontalis, a species from China and the Himalaya, has been known for upwards of thirty years. Grown in the open, it forms a low, spreading bush about one and a-half or two feet high, with a flattened branch system, but against a wall it may attain a height of twelve feet. The elliptical leaves are usually half an inch or less in length, though they sometimes grow larger, and are borne with considerable freedom. They are dark green in summer, but change to scarlet and gold previous to falling. The flowers are small, but the scarlet fruits are conspicuous. When grown against a wall both fruit and coloured leaves are seen to better advantage than when the plants are grown in the open.

W. DALLIMORE.

(To be continued.)

A USEFUL EVERGREEN WINTER SHRUB.

Among the plants that will enliven and beautify the flower garden in winter Pernettya mucronata claims much consideration. Yet it is rather astonishing how often this plant is overlooked by writers treating on the claims and values of decorative shrubs for the garden in winter. This forces the thought to my mind that it cannot be very well known. However that may be, it is, I venture to assert, one of the most useful ornamental evergreens we have. Of dense, low growth, it makes a capital winter bedding subject, used en masse, or it forms a good edging to a shrubbery. My experience has shown it to do best in partial shade, though it will thrive in sun or shade, providing the sunny position has a good moist root run, and in either situation it will respond most healthily where the soil is light and rich.

The pretty, myrtle-like foliage is accompanied in summer time by an abundance of small, whitish flowers, which, in turn, are followed in winter by clusters of pink berries. In some plants the colour of the berries varies slightly, but creamy-white to reddish-purple would describe the colour of all the varieties, and it is these varying shades of colour which relieve the dulness and give a more cheerful tone to the landscape in winter.

Besides being helpful in the ways suggested, pernettyas are good pot plants for the cooler houses, and their propagation is quite easy, namely, by seeds, cuttings, or division of root stocks.

Ken View Garden, Highgate, N.

SUCCESSIONAL DESSERT PEARS.

One of the most important details that should be given attention when the pears are being planted in private gardens is choosing the varieties to secure a regular and sufficient supply of choice fruit throughout the pear season. It is therefore expedient to make selections of the best pears which ripen at suitable seasons, and this can only be done satisfactorily by those having a thorough knowledge of varieties. Though it is most unpleasant to have a glut of ripe pears at any time, it is nevertheless inadvisable, unless restrictions of space necessitate it, to endeavour to maintain a supply by dependence upon the least possible number of varieties. If this restriction is attempted, interruptions in the supply, even in years similar to that of 1912, when pears generally cropped heavily, will assuredly occur, because one or another of the sorts will prove disappointing.

Pears grown in open quarters are unreliable croppers, and any variety is liable, at times, to failure, or to produce an unusually large crop. For instance, this season, when the pear crop was unusually bad, and when here all other varieties have been either fruitless, or nearly so, Souvenir du Congrès has carried heavy crops of fine fruits.

Although the pear is an uncertain bearer it has been considerably improved in this respect, and also in its earlier development. Formerly it was stated that "the man who plants pears, plants for his heirs"; but proficiency in culture, and improvement in the stocks employed for grafting, double grafting, and root-pruning, have quite revolutionised that state of affairs, and those who are careful to secure skilfully prepared trees, plant them properly, and subsequently carefully attend to them, need not dread unprofitable results.

Reference has been made to the occasional glut and consequent waste, but it is better to plant duplicates of the most valuable varieties, such, for example, as Doyenne du Comice, Thompson's, Marie Louise, and Louise Bonne of Jersey, than to risk having a short supply. Moreover, it is advisable to prolong the season of such sterling sorts by planting trees in different positions, and likewise by gathering the fruit at suitable intervals, or by storing it under varied conditions of temperature.

Some readers may think these notes wanting in value unless they contain a definite list of the least number of varieties that would give (provided they all carried crops) an unbroken supply throughout the season. Such a list, I regret to say, I do not feel qualified to give; but will conclude by venturing the names of those pears I believe will fulfil the end in view; but, as has been previously remarked, it is not advisable to depend upon a strictly limited number of varieties.

Though there are a few earlier kinds, I will commence my list with an August variety, viz., Jargonelle, and follow on with successional varieties—William's Bon Chretien, Souvenir du Congrès, Beurré d'Amanlis, Fondante d'Autômne, Marguerite Marrillat, Beurré Hardy, Louise Bonne of Jersey, Beurré Superfin, Marie Louise, Emile d'Heyst, Charles Ernest, Doyenne du Comice, Conference, Thompson's, Princess, Beurré d'Anjou, Glou Morceau, Winter Nelis, Le Lectier, President Barabe, Huyshe's Victoria, Josephine de Malines, Easter Beurré, Marie Benoist, Nec Plus Meuris, Bergamotte d'Esperen, Oliver de Serres, and Beurré Rance.

THOS. COOMBER.

The Hendre Gardens.

CROWN ANEMONES.

Notwithstanding their great beauty, the varieties of Anemone coronaria, variously known as Poppy or Crown anemones, are not very well represented in gardens, except in the western and south-western districts and through the fen-lands. No doubt a moist root run and a moist atmosphere are both conducive to success, but the former can be provided by any skilful cultivator, who, if he provides also a rich soil for the plants, will not find the effect of a dry atmosphere, such as prevails in the suburbs of large towns, so great as is generally supposed. The robust St. Brigid strain provides a wonderful variety of colouring, and this and the selected forms may be obtained and planted any time from October until April to secure a succession of flowers. There are double and single forms, all of great beauty, but one of the most useful and charming is

ANEMONE CORONARIA THE BRIDE.
A lovely variety with large white flowers.

The Bride, which has large white flowers eminently suitable for cutting and use in the home, as well as for garden decoration.

MONTANOA BIPINNATIFIDA.

Some half a dozen years ago a group of this montanoa was shown at one of the winter meetings of the Royal Horticultural Society, when an Award of Merit was given it. As a winter-flowering plant it was almost unknown, though it had been long used in subtropical bedding under the name of Polymnia grandis. It may be flowered freely when from three feet to six feet in height, and is valuable for grouping purposes. Montanoa bipinnatifida forms a stout, erect stem of a half-shrubby character, clothed with large, oppositely arranged, much divided leaves, the divisions, in their turn, being deeply cut, hence the specific name of bipinnatifida.

The flowers, somewhat suggestive of a single dahlia, are freely borne on the upper part of the plant. They are about three inches in diameter, the florets being white and the central disc yellow. It is a plant of easy propagation and culture, and the fact that it flowers in the winter is a great point in its favour. S. W.

SOLOMON'S SEAL AS A POT PLANT.

Those who have never tried them will scarcely believe what useful pot plants Solomon's Seal will make, but, though they look well even in the conservatory when forced in January or February, it is their use as indoor plants for those who have little or no greenhouse accommodation which constitutes their principal value, for they will last as foliage plants for six or eight weeks. The tubers should be lifted from October to December, and prepared for potting by cutting them into lengths of two to four inches—retaining, of course, the crown ends for potting—for without cutting it is impossible to get enough crowns into a medium-sized pot, say, a 24 or a 32, to make a presentable specimen.

Besides this, if whole lengths were put into large pots the resulting growth would be so tall that they would be too leggy for success as indoor plants, whereas by growing them half their normal size under good conditions, and having a few small ones mixed with them, a nice bushy group is obtained.

As many pieces should be put in a pot as it will hold, and fine soil shaken down between them, after which the pots may be set in a cold frame or buried in cinder ashes. They may be brought into a warm house and forced from Christmas onwards, or, if no such facilities exist, grown naturally for bringing indoors as soon as the flower buds begin to show. A succession may be obtained by putting the first two or three pots in a warm corner in the frame or greenhouse to start them, keeping others under a north wall.

When done with as pot plants in May or June, the plants may be put out whole in any out-of-the-way place, or even kept as they are for a second season, but the latter course implies attention in the matter of watering all the summer.

ALGER PETTS.

PINKS FOR THE ROCK GARDEN.

Among the dianthuses, or pinks, which await the specialist in this exquisite genus of plants we have an embarrassing choice for those who only wish to cultivate a few of the best in their rock gardens or on their little rockeries. They are indispensable—or, at least, some of them—and they are always highly appreciated when in bloom. Even when not in bloom many of them are objects of pleasure to all who love their flowers.

They are not difficult to cultivate as a rule, and a light loam will suit the majority. Some, however, prefer the moraine, and practically every one of these beautiful plants desires plenty of sun. A few require a little lime in the soil if they are to attain their fullest beauty, and those with glaucous leaves are more particularly lime-lovers, delighting in the addition of some lime-rubbish or limestone chips to the compost.

Of the pinks for the rock garden none can well surpass the lovely Dianthus alpinus—the Alpine Pink—which, when happy, makes spreading tufts of glossy leaves surmounted by glowing rose-coloured flowers of the most charming hue, and only raised some two inches above the shining carpet of green whence they spring. A charming plant is this, and one which is most at home on the limestone rocks, or in loam with lime mixed with it, or in the moraine. It is a sine qua non, and all rockeries or moraines should possess it.

Equal in value, in the estimation of the writer, is Dianthus neglectus, but it must be added that this is a variable species, and some of the plants supplied are from seeds and are of different grades of merit. It grows to some three inches in height (or a little more with some inferior varieties), and affords us a supply of brilliant carmine flowers which, in the true species, are coloured buff on the outside. But there are many poor plants of this pink in cultivation; some are poor in colour, some are taller and less refined; and the reader should seek in the nurseries for a compact, low-growing plant, with grassy leaves, and large, brilliant carmine flowers. It grows readily in loam and grit. Some find it does well in the moraine, but others have a contrary experience.

The Cheddar pink, Dianthus cæsius, as we see it in gardens is a variable species. Many of the plants appear to be hybrids, and only a small proportion have the neat habit and the pretty pink flowers of the native Cheddar pink of the famous cliffs. It makes good masses, however, and wants to be kept poorly fed if it is to be neat and compact as we would like to have our plants in the choice rockery. It has a companion in D. suavis, which resembles it considerably.

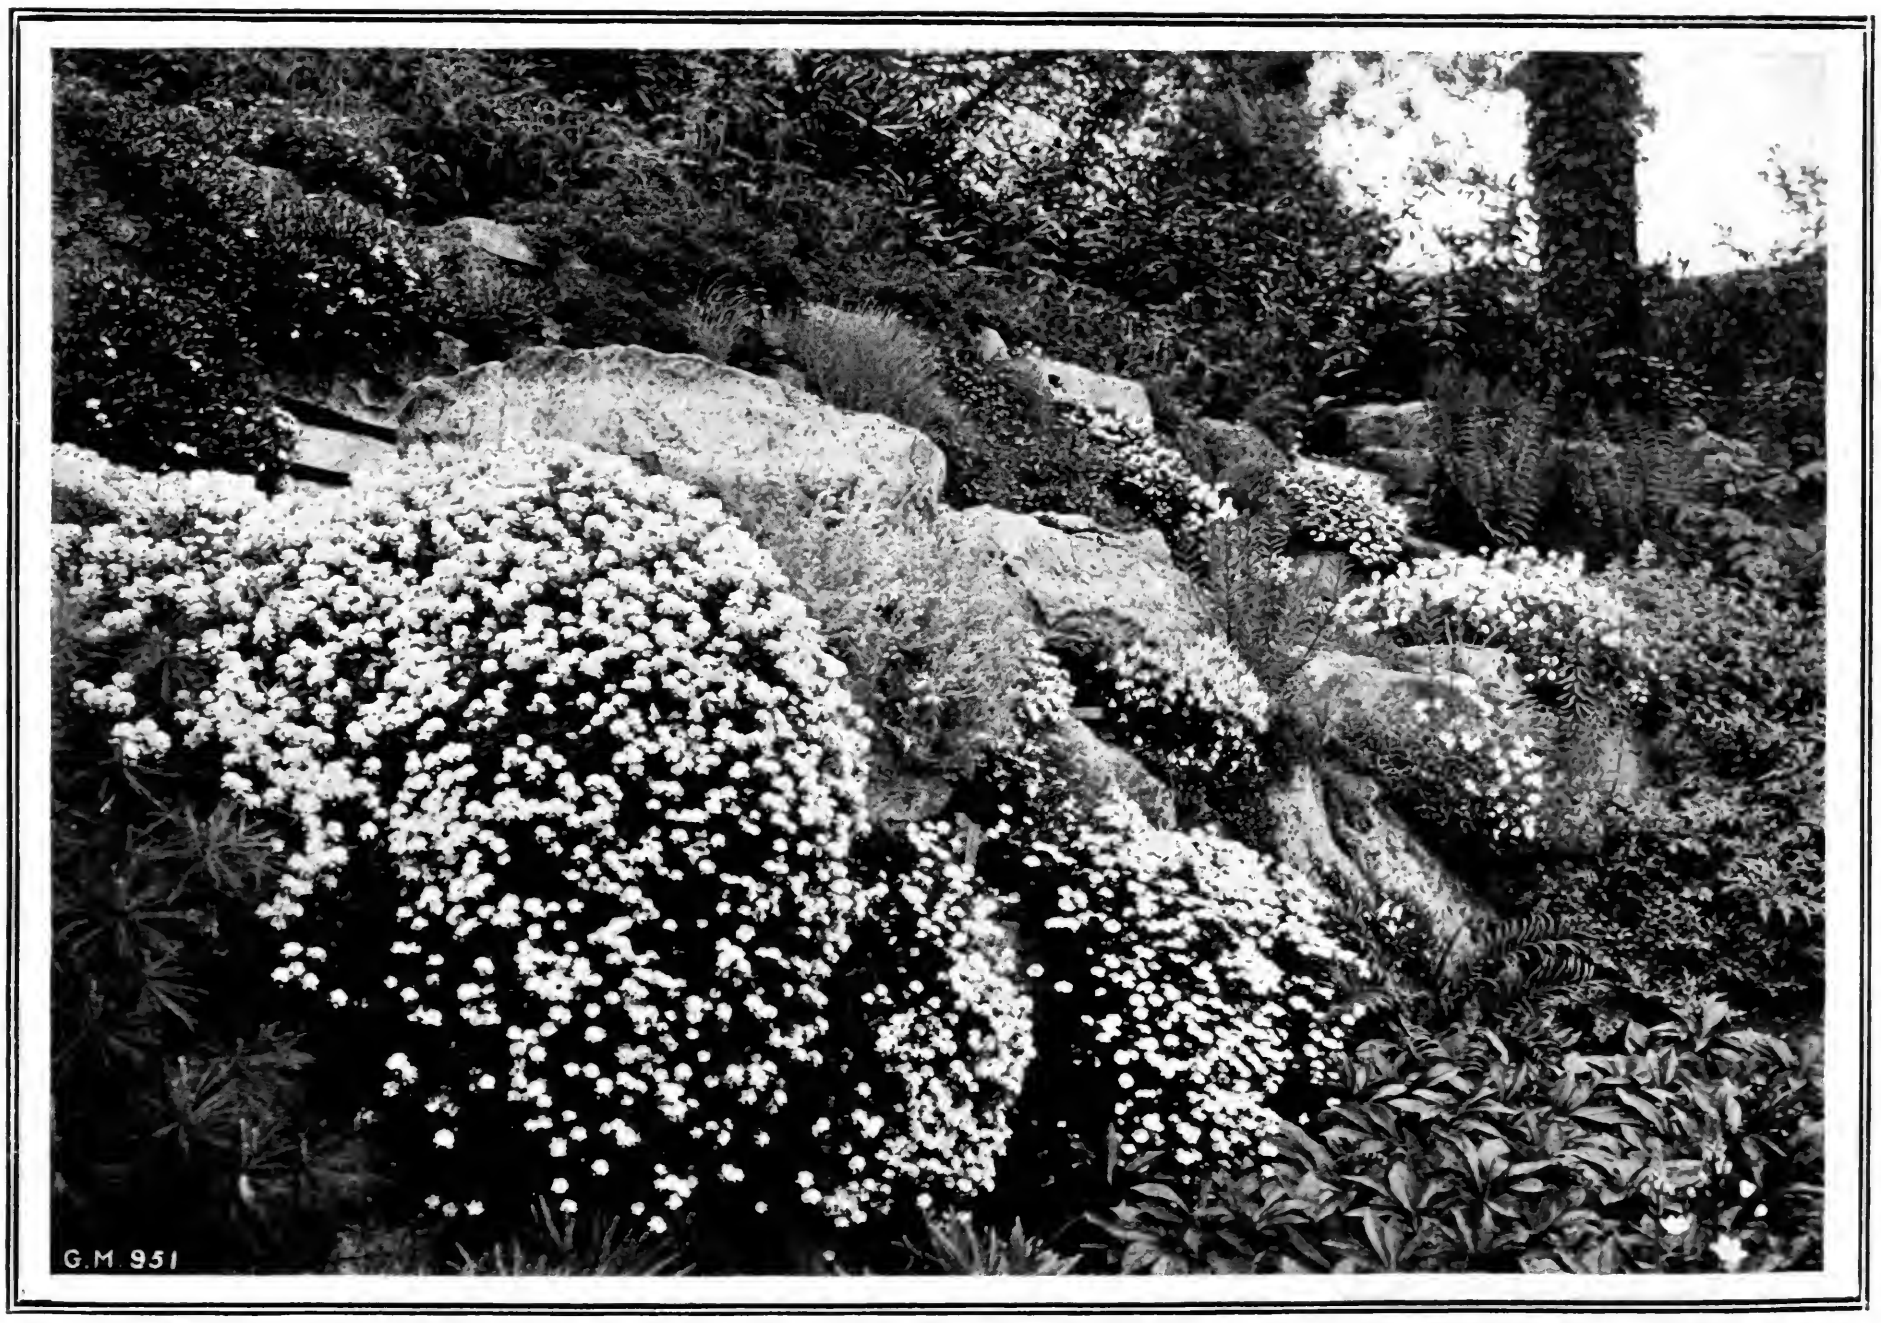
As for the Glacier pink—Dianthus glacialis—we may say that it is a fair maiden of a coy temper when on the rockery. It likes a moraine best, and there will generally prove itself less testy and capricious, and be more likely to thrive, and to raise above its glossy leaves its solitary rosy flowers on stems two inches high.

In D. Freyni we have a little gem, dear to the heart of the lover of the tiniest and daintiest alpine flowers. It has tiny leaves, almost close-set on the soil, or forming tiny mounds. Thence rise little rose or rose-purple flowers. It has near allies in D. Lereschi and D. microlepis. In a dry, gritty compost of loam, sand, and grit, and surfaced with an inch of fine grit, these all thrive well. But on no account must they be parched by drought. Should they be threatened with this, some water should be given at the roots of these dainty gems.

Practically everybody loves the Maiden Pink, D. deltoides, with its tufts of green leaves and its rose or white flowers, prettily zoned with a deeper tone. It has a glorified sister, in the shape of D. Graniticus, the Granite Pink, which is taller and has bigger flowers. These will do almost anywhere, in sun or partial shade.

Dianthus squarrosus is a pleasing little pink, making a close carpet of grey leaves, and giving an abundance of fragrant, fringed blooms. D. frigidus is another nice dianthus with handsome pink flowers on short stems. It is a form of D. sylvestris. A charming flower, but not one of the easiest to grow, is D. callizonus, which delights everybody who sees it. Its flowers, on two-inch stems, are very large for such a plant, and are brilliant crimson, zoned with deep crimson spots in a fascinating way. It likes a rather peaty soil, but full of stones, and best enjoys partial shade.

A pretty pink of considerable beauty is D. arvernensis, the Auvergne pink, which is a miniature Cheddar pink, and suited



EVERGREEN CANDYTUFTS FLOWERING IN A ROCKERY WALL.

(See opposite page.)

for a rockery in a small garden; while D. superbus is about six or eight inches high, and gives rose or white flowers. It is often highly praised, but to the writer appears less worthy of our admiration than some of its sister flowers. There are many more—such as the fringed, white-flowered D. integer, and the dainty hybrid Spencer Bickham. S. ARNOTT.

Dumfries.

EVERGREEN CANDYTUFTS.

The evergreen candytufts form a charming little group of free-flowering shrubby plants, suitable alike for the rock garden, the margin of the shrubbery, or the herbaceous border; nor must their merits be overlooked when any scheme for a spring display in the flower garden is being drawn up. Propagation is best effected by means of cuttings, taken soon after the flowering season has passed, and inserted firmly in sandy soil. In most gardens it is advisable to shelter the cuttings in a cold frame or under handlights, choosing a site open to the light, but which does not receive direct sunshine. A border on the north side of a wall will generally be found a suitable position. Given reasonable care such cuttings will soon develop into neat little tufts, which will give a good account of themselves when they blossom in May and June.

Both Iberis saxatilis and I. semperflorens very frequently flower in late autumn and early winter, or even early in the year, as well as during the spring, provided the weather is kind; and one may find I. semperflorens in bloom at present in many gardens. The best of the evergreen species are Iberis saxatilis, which, with I. semperflorens, commences to bloom in March in an ordinary season. The first-named is about six inches high, but I. semperflorens will often reach eighteen inches. I. sempervirens is particularly hardy and a fine subject for a wall garden or the steep places in a rock garden, for under these conditions it, and its variety Garrexiana, become long, drooping masses of greenery, and, at flowering time, sheets of snowy blossom. Compact, large-flowering varieties of I. sempervirens are Climax, Little Gem, Perfection, and superba; Little Gem and superba are capital plants for borders, and are also excellent in suburban gardens. All these evergreen candytufts have white flowers.

C. K.

Garden Suburb at Tottenham.—In the development of the White Hart estate at Tottenham, the London County Council will expend about £23,468, so that the district may become a garden suburb instead of a dense mass of houses.

ALPINE PHLOXES.

The value of the dwarf alpine phloxes for the rock garden or the flower garden cannot well be overestimated, therefore, without entering into a long discussion upon their respective merits or their specific differences, it is important that garden lovers should be reminded of these exquisitely beautiful and easily grown subjects. Perry's variety of Phlox Laphami is a giant as compared with those named below.

A dozen or so of first-rate varieties, all of which are listed and described in hardy plant catalogues, will serve to show the range of colouring available, but there are others besides for those who desire to make a collection. P. annulata, pale blue; amœna, pink, a lovely shade; atropurpurea, deep rose-purple; Daisy Hill, rich rose; G. F. Wilson, mauve, sometimes nine inches high; lilacina, deep lilac; nivalis, pure white, very compact; procumbens, a lilac-flowered, purplish-leaved trailer; Seraph, mauve, with dark eye; Sprite, rose, with crimson eye; frondosa, a dark-eyed pink form of P. subulata; The Bride, white, with pink eye; Triste, self pink, violacea, lilac; verna, rose-red, a closely-creeping form; and Vivid, bright pink or rosy-carmine, with crimson centre. These will form a very pretty collection. The last-named variety is herewith illustrated as growing at the Feltham Nurseries of Messrs. T. S. Ware, Lim. B.

ALPINE PHLOX VIVID.

A beautiful dwarf garden form, with carmine, crimson-eyed flowers.

CLERODENDRONS.

In few genera is such a marked difference of form shown as in clerodendron. The species differ considerably in habit, cultural requirements and many other features.

The Japanese Clerodendron trichotomum, and the nearly allied C. Fargesii, are quite hardy, and form large shrubs, or almost small trees. Another hardy species is C. fœtidum (or C. Bungei; as it is often called). This, though classed as a shrub, dies almost to the ground during the winter, in the manner of a herbaceous plant.

A great many species are climbers, principally natives of tropical Africa, and are seen at their best in the stove or intermediate house, while several of those that come from tropical Asia are of more or less shrubby character.

Of the climbing kinds the best known is Clerodendron Thomsonæ, which, however, is far more generally met with under the specific name of C. Balfouri. This is of free growth and forms a delightful feature when trained to roof or rafter in a warm house. Under these conditions it will grow freely, and flower in great profusion. The blossoms, which are borne in large branching panicles, are of a bright crimson colour, and protrude each from a large, inflated, pure white calyx, which retains its freshness after the blossoms have faded. This large calyx is a more or less marked feature of several of the species. C. Thomsonæ was at one time very popular for growing into large specimen plants. There is a form of it in which the calyces are striped with red. C. splendens, which comes from Sierra Leone, is less vigorous than the preceding. It also requires the warmest part of the stove, where its large, branching panicles of rich scarlet flowers form a very striking feature.

Between the two species just named, a hybrid, bearing the name of C. speciosum, has been raised. The flowers are of a less pronounced scarlet than those of C. splendens, while the inflated calyx is of a ruddy hue. It is more free in growth than this species, and the plants from this parent will succeed in a somewhat lower temperature.

C. ugandense has a rambling rather than a climbing habit of growth. It is, as implied by the specific name, a native of Uganda, and is of comparatively recent introduction. A singular feature, in which it differs from all the generally cultivated clerodendrons, is that the flowers are of a blue tint. In this clerodendron the flowers are borne in loose terminal panicles, and of a distinct shade of pale blue, while the lowermost of the five segments is of a darker tint. It will grow under cooler conditions than the preceding, and is likely to prove a desirable rafter plant for the greenhouse. It can be readily raised from cuttings. C. cœrulea is another name for this species.

The clerodendrons which are more or less shrubby include some very desirable garden plants, the best known being the Javanese C. fallax. This is largely grown for greenhouse and conservatory decoration during the summer months, for, though it needs a moderately warm temperature during the growing season, it will thrive in the greenhouse during the summer. It is readily increased from seeds or cuttings, and, in order to have the erect panicles of deep scarlet flowers at their best, occasional doses of stimulants are necessary as the pots become well furnished with roots.

C. squamatum, also known as C. Kæmpferi, is a good deal like the preceding, and succeeds under the same treatment; the berries, when ripe, are of a pleasing blue tint.

C. fragrans, a very old plant in gardens, is generally represented by its double flowered form—C. fragrans flore-plena. In this, the flowers, which are borne in a terminal, rather compact, hemispherical head, are very double, white, flushed with pink. It will conform to the same treatment as C. fallax, and, like that species, may be used in summer for greenhouse decoration. Though the blossoms are so fragrant as to warrant the specific name, the leaves, when handled, have a very unpleasant smell.

C. myrmecophilum is an exceedingly distinct, shrubby species, and was first shown by Messrs. Sander and Sons on April 5, 1904, when a First Class Certificate was given it by the Royal Horticultural Society. It was, however, grown at Kew previously to this. This species forms an erect-growing plant that will flower when from eighteen inches to two feet in height. The leaves are lanceolate in shape, and larger than in most of the clerodendrons. The flowers, borne in an upright panicle, are disposed in a strictly pyramidal manner, and in regular whorls. They are about one and a-half inches across, and of a bright orange-amber colour. The long slender stamens are bright red, and, as in some other species they form a conspicuous feature of the flower. From its distinct colour it forms a very striking plant in the spring and early summer. It is a native of Singapore.

An old species, but one not often met with, is C. nutans, which used to be well grown by the late Mr. Head, when at the Crystal Palace, and an example shown by him was given a First Class Certificate by the Royal Horticultural Society in 1886. In this species the white, sweetly-scented flowers are borne in loosely-disposed pendulous panicles. They are, as a rule, at their best during the autumn and early winter months.

This list of tender clerodendrons might be considerably extended; but those named include the best, and most of them can be readily obtained from nurserymen.

Among the hardy kinds the first place must be assigned to C. trichotomum, which will attain a height of a dozen feet or more. If kept to a single stem it becomes quite tree-like in growth, whereas if left to itself it will often push up suckers and form a dense bush. The leaves vary a good deal in shape, but on old plants they are usually ovate. The flowers are at their best in early autumn, pure white, fragrant, and borne in rather dense panicles. A conspicuous feature is furnished by the large red calyces, which retain their brightness for a considerable time. The bluish-violet fruits sometimes ripen, and then form a pleasing additional feature. The warm reddish-purple of the decaying leaves is also very attractive.

C. Fargesii, much like C. trichotomum, of which it can scarcely be regarded as anything but a variety, is more shrub-like, but very free-flowering. The bright blue berries, when ripe, are very attractive, and two years ago some fruiting sprays found so many admirers that the species was given an Award of Merit by the Royal Horticultural Society.

C. fœtidum, another hardy species, but one that needs a warm spot at the foot of a south wall, dies nearly, if not quite, to the ground in winter, and in spring pushes up stout, erect shoots, four to five feet in height, furnished with prickles. The large heart-shaped leaves are rough in texture. The flowers are borne in closely-packed heads, and are usually at their best towards the end of the summer. They are of a bright rosy-crimson colour, and have a honey-like fragrance. The specific name of C. fœtidium is derived from the unpleasant odour of the foliage. This species is a native of China. W. T.

FRAGRANT ROSES.

When reading the announcement in THE GARDENERS' MAGAZINE of the splendid presentation by Messrs. Clay and Son, of a challenge cup, for the encouragement of roses possessing the fragrance of the old Cabbage of Provence roses, I could not help thinking how this offer would have delighted my old employer, the late Lord Penzance, for in all our experiments the one aim was to retain scent. Perhaps it may not be out of place if I note the various experiments in this direction. Firstly, it is well known that his Lordship was so struck with the delicious perfume of the common sweet briar that some three years before I entered his service he had commenced to hybridise the sweet briar with various roses of the hybrid perpetual and hybrid China section. I need not refer to the results, as they have been long before the public.

But there were other experiments that have not, to my knowledge, been chronicled. It was found that in trying to enlarge or to double the flower of the hybrid sweet briars by re-crossing them, although seeds and plants were freely produced, fragrance was entirely lost, both in flower and foliage; the leaves became like those of the H.P. or H.C., as the case might be, and the rampant growth of the hybrid briar was dwarfed to that of the hybrid perpetual. Secondly, in crossing the Provence rose with the gallica or Panachee varieties, or the latter with such H.P.'s, as Gèneral Jacqueminot and Madame Elise Taisson, Madame Boll, La Rosière, etc., roses of the type of the hybrid China were produced, like Chenedole, Paul Perras, etc., and in no single instance were any of them perpetual. Nevertheless, we always found in these results the most delicious fragrance imaginable.

There is one rose I would urge rosarians not to lose sight of in trying for delicious perfume, and that is the old Blairi No. 2, for I know of no other rose with such a lemon scent. Then, again, there are the Moss roses, so closely allied to the Provence, and most prolific seeders, but I am doubtful if any good is to be done in this direction; any number of moss roses may be raised, but among hundreds of seedlings I never saw one showing any advance upon its parents. The Musk rose lends itself very freely to the hybridist, combining with H.P. or T., or, I think I may say, any variety one feels inclined to favour it with. It produces large quantities of fertile seeds. I will here present a suggestion to anyone who may care to try it, and that is to procure a plant or two of Musk rose Princess de Nassau, and cross it with the pollen of Harrisoni, and I have good grounds for thinking the progeny will give a pleasant surprise, and start a race that will further help to beautify our gardens. But I am wandering from the subject of "The Clay Cup," and will not trespass further on your valuable space.

ROSES FOR GARDEN DECORATION.

At a recent monthly meeting of the Cirencester Gardeners' Association Mr. Edward A. Jefferies read an interesting and highly instructive paper on "The Selection and Cultivation of Roses for Garden Decoration." Mr. Jefferies briefly referred to the rose gardens that were a source of disappointment to their owners, and said: In such a garden the roses were planted perhaps eight, ten, or fifteen years ago in badly prepared beds or borders, and have not been replanted since. The varieties planted were perhaps chosen from blooms seen exhibited in a first prize box at some show or other, and planted without any regard for the different habit of growth of the various sorts. The owner of the garden cannot imagine why some of his plants, although they make strong growth, never bloom. A casual glance shows that in this case the stock upon which the rose was budded has been allowed to overgrow and smother the poor rose. And probably in the same garden we shall find fault number four, namely, plants that are living and doing fairly well are all bare and leggy at the base and the growths crowded together at the top of the plants, the result of faulty pruning or no pruning at all. I believe more roses are ruined by their owners refusing to allow their gardeners to prune their roses as they should be pruned than from any other cause.

Bedding Roses.

In the case of rose gardens it is preferable to keep to one variety to a bed, the effect is certainly better both as regards colour and mass of bloom, and also you have an evenness of growth that it is difficult to obtain when planting three or more varieties in the same bed. As to the best varieties to grow, assuming that a rose garden has just been planned and made, and that the owner requires good bedding varieties, he will want roses that are continuous and free-flowering, of not too rampant a growth, not too addicted to mildew, and distinct in colouring; and, lastly, varieties that carry their flowers erect. The following varieties comply very closely with these conditions: Lady Ashtown, pure deep pink colour, and considered the best of the pink bedding roses; Caroline Testout, bright pink, a fine rose in all weathers; Mdme. Abel Chatenay, everyone knows this fine decorative variety, salmon pink best describes its colouring, particularly good in autumn; Madame Ravary, deep golden-yellow, perhaps the best yellow bedding rose, though Harry Kirk, bright sulphur yellow, and Lady Hillingdon, bright orange yellow, run it very closely, the bronze red colour of the young wood and foliage of Lady Hillingdon makes a very pleasing setting to the bright yellow blooms; Madame Jules Grolez, described as a deep rose-pink, but a colour unlike any other pink rose, it requires care in placing, for it clashes with other pinks, and should be put in a bed that is in the neighbourhood either of clear yellows or pure white roses; Antoine Rivoire, pale cream with deeper centre, a great beauty, fine early and late; Molly Sharman Crawford, eau-de-nil, white; Madame Melanie Soupert, pale yellow flushed delicate pink, excellent; Mrs. Aaron Ward, Indian yellow petals edged white, very attractive; Madame Antoine Mari, rose and blush white, foliage almost evergreen, especially good in the autumn; Richmond, glorious crimson, and flowers of perfect shape, very fragrant.

General McArthur, bright scarlet crimson, the best crimson bedding rose; Ecarlate, bright scarlet, an excellent bedding rose, always in bloom, but perhaps would not be chosen by everyone, as the individual blooms lack form, but the plant is so very continuous in flowering that this fault may be excused; Mrs. Alfred Tate, coppery salmon, shaded fawn, very lovely in the bud stage, one of the best; Pharisaer, rosy-white, shaded salmon, excellent in the autumn and good throughout the season; Joseph Hill, coppery-yellow, shaded apricot, charming foliage; Viscountess Folkestone, cream-white, shaded flesh, introduced as far back as 1886, but still one of our best bedding roses; Marie van Houtte, lemon-yellow, petals edged with rose; Betty, coppery-rose, shaded yellow, very pretty in the bud; Mrs. Wakefield Christy Miller, a charming rose, inside of petals soft blush, and the reverse of petals deep rose, a charming combination; Lady Pirrie, deep coppery-salmon, a delightful rose; Irish Elegance, a beautiful single flower, shades of apricot, and buds orange.

While referring to bedding roses I should like to mention two of the dwarf polyantha varieties, Orleans and Jessie, the former a vivid rosy-crimson, and the latter a cherry-crimson, both are excellent for bedding, and from the end of June until October beds of these varieties will be a mass of colour.

Of the foregoing twenty-four varieties, nineteen are hybrid teas, five are teas, and not a single hybrid perpetual amongst them, not that many of the H.P.'s are to be despised for bedding, for Hugh Dickson, that grand crimson rose, had my list extended to one more, would have been the selected one, and Frau Karl Druschki, Ulrich Brunner, Mrs. John Laing, Mrs. Sharman Crawford, Captain Hayward, to mention no others, are good bedding roses, but just miss, in my opinion, being amongst the best twenty-four for the purpose.

My list shows what a great change has been made in the rose world during the last twenty years, for, with two exceptions, none of them were in commerce in 1893, and by far the largest proportion have been sent out during the last ten years. Did you intend growing roses for exhibition my list would be a very different one, and of the twenty-four varieties I have mentioned, only Lady Ashtown, Caroline Testout, Molly Sharman Crawford, Madame Melanie Soupert, and Pharisaer would be suitable for competitive purposes, and though it by no means follows that exhibition varieties are not good for garden decoration (many are excellent for both purposes), yet an exhibitor will be obliged to grow such roses as Mildred Grant, Bessie Brown, William Shean, and Florence Pemberton, varieties which, had it not been for the exhibition boxes, would, I think, have disappeared from cultivation ere this.

The Making of an Ideal Rose Bed.

The rose-lover should not say that he cannot grow roses in the soil of his or her garden. I am prepared to say that the soil may be a heavy clay soil, a light soil, a sandy soil, a chalky soil, soil with gravel as a subsoil, or any other kind of soil, and with proper preparation you can grow good roses. Good drainage is essential, for roses will not thrive in a water-logged soil, but we must not forget that the rose is a moisture-loving plant, and therefore the soil must be made retentive.

The ideal soil for roses I should describe as two feet of rich loam of a greasy nature, a subsoil of clay, and good drainage beneath, and if we have not this in our garden (and few of us have) in making rose beds we must try and as closely approach it as possible. If yours is shallow land, on gravel, a light loam, or chalk soil, my method of preparation would be this. Dig out and put aside the top soil, which we will suppose is six inches deep, then dig out and take right away the next eighteen inches or two feet of gravel, brash, or chalk as the case may be. The drainage of these subsoils will probably be naturally good, so that beyond forking up the bottom nothing more will be needed to ensure perfect drainage. Having thus dug the bed out from two feet to thirty inches deep, I should fill up the bottom of the bed with a layer of clay to a depth of about six inches; upon this wheel in a layer of loam, or the top spit from a heavy pasture, then a layer of old cow manure, then again a layer of turf or loam and another layer of manure, and so on in this manner until the hole is filled up to within nine inches of the top. Then turn to the heap of soil that was taken out of the bed, and, if it is very poor, incorporate some leaf soil and a dressing of quarter-inch or bone meal, mix well, and fill in with the mixture. When filled the level of the bed should be quite six inches above the surrounding ground level to allow for sinking.

On a heavy clay soil the same preparation applies, except that it will be necessary to dig out the beds three feet instead of two, and fill up the bottom nine inches with stones, burnt clay, broken bricks, or clinkers to ensure drainage; upon this replace the clay, then the loam and cow manure in layers, and lastly the top soil as previously explained. If this top soil is very heavy it will be improved and made more friable by the addition of burnt earth and wood ashes, mortar rubbish, and road sweepings; but a word of caution about the latter—do not get the sweepings either from a tarred road or from a road much frequented by motors.

The rose bed or rose garden should be in the open, away from trees and walls, and for preference facing south or west. The shape of the beds depends very largely upon local conditions, but my ideal bed is one with a width of five feet, which will allow for three rows of plants. The length is unimportant, but the simpler the design of the bed the better the effect. I would always have the rose bed surrounded by turf.

The principal things to remember in planting roses are to make the hole large enough to take the roots easily, deep enough for the junction of the rose and the stock to be one inch below the surface, and to plant firmly, the latter being most important.

Pruning.

It is perfectly safe to make a rule that all roses the first spring after planting should be pruned to within three or four inches of the ground. Even climbing varieties should not have more than twelve or eighteen inches left of their strongest growth. It may seem a great pity to cut away four or five feet of growth that if left would seemingly furnish the arch or pergola with blooms the first year after planting, but harden your heart and prune, and the results the second and after years will amply repay you.

Pruning after the first year of planting will need to be varied according to the varieties and the purpose for which they are grown. Those intended for exhibition will need harder pruning than those for garden decoration. Strong growing varieties, as Hugh Dickson, Frau Karl Druschki, J. B. Clark, will only need shortening back to about eight inches from the base, whereas less vigorous growers will need to be pruned back to four or six eyes from the base. The shoots should always be pruned to an eye pointing outwards, and, of course, all dead or unripe wood should be cut clean away. Climbing roses should have some of their old shoots cut clean away each season directly after their first flowering. This encourages fresh growth from the base, and keeps the arch or wall well clothed at the bottom.

But rose pruning is a big subject to thoroughly master, and enough could be written to make a paper on this subject alone, so I will leave it with the remark that a little publication, called a "Handbook on Pruning Roses," published by the National Rose Society, will give you detailed information for pruning nearly every rose in commerce. It should be in the possession of every rose grower.

(To be continued.)

WORK FOR THE WEEK.

THE ORCHID HOUSES.

SEASONABLE NOTES.—In the cool divisions many orchids are completing their pseudo-bulbs, and the bulk of the plants are in an active state. It is only during the last few years that writers on cool house orchids have advocated an advance on the winter temperature of 45 degrees, formerly regarded as suitable conditions for odontoglossums. Under the old treatment the plants produced poor growths, and pseudo-bulbs generally much smaller than the imported ones. Latterly, cultivators have realised the same rule may be applied to the cultivation of odontoglossums as to all other classes of plants—that is, the period when they require the most encouragement is when they are most active—and the now general practice of keeping the temperature at night at about 53 to 55 degrees has proved in every way satisfactory. Not only have we stronger plants capable of carrying larger spikes of flowers, but, what is more important, we have been able to produce seedlings of both generic and bigeneric hybrids, which, until a few years ago, were considered almost impossible. With the warmer conditions at night, and with favourable outside conditions, more fresh air can be admitted to the houses, thus providing an atmosphere which will allow the potting compost to become dry in a reasonable time, and so do away with stagnation, which was a great bugbear under the older and cooler conditions.

CARE OF THE FLOWER SPIKES.—When the flower spikes make their appearance, slugs, snails, and woodlice will become busy. Small pieces of cotton wool wrapped round the base of the flower spike, form an obstacle difficult to surmount, and while it may not altogether prevent harm, it certainly helps to keep the pests away. Lettuce leaves spread about the stages and on the surface of the potting compost, and small portions of bran or brewers' grains laid on pieces of glass or broken crocks, make good feeding grounds, and, with the aid of a light during the evening and early morning, many slugs, etc., may be caught and destroyed on them. Where young plants are flowering for the first time at this season of the year the spikes may become drawn and weakly, especially in lofty structures; it is therefore a good plan to suspend such plants near the roof, or raise them up nearer the light.

THE ODONTIODAS are now a fine feature, and with a good selection of kinds it is possible to have their attractive colouring at all seasons; we find they are more vigorous than the odontoglossums, and they are grown under similar conditions. Thrips are the only insect pests that trouble the flower scapes, but fumigation or vaporising effectually keeps these pests in check during the winter season.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

BEGONIA GLOIRE DE LORRAINE.—The main batch of this most useful begonia is now at its best, and, with the object of keeping the plants as long as possible, the temperature should be somewhat reduced; 65 or 57 degrees on mild nights, and a little lower when the weather is cold, is sufficient. Damping down will be quite unnecessary, and a little air should be given by means of the roof ventilators in the day time, so long as the temperature is at 60 degrees. The latest batch should be allowed to flower, and will provide useful material well into the new year. Of the early batches, now past their best, the cleanest and healthiest may be lightly trimmed over, and given a month or six weeks' rest by keeping them rather dry in an intermediate house, after which they may be placed in the stove to provide the earliest cuttings.

THYRSACANTHUS RUTILANS is now fast elongating its pendulous racemes, and until the flowers show colour may continue to receive occasional applications of fertiliser. Water should be applied with care, and too close an atmosphere must be avoided, otherwise many of the leaves will fall. Brown scale is particularly partial to this plant.

ALLAMANDAS, where planted out and grown on rafters or trellising, may now be pruned to within an eye or two of the old wood; and until they are again commencing growth should be kept dry at the roots. Specimen plants in pots may also be pruned, and should be kept in a cooler house, and dry, until required for starting in the spring.

MARANTAS AND BERTOLONIAS, both remarkable for their beautifully marked foliage, and alike at home through the warm seasons in a close, moist atmosphere, should, through the winter, be kept at the warm end of the stove. Until the growing season arrives a judicious use of the water-pot will be essential.—H. Prime, Hatfield Gardens.

FRUITS UNDER GLASS.

GENERAL WORK.—During this month a quantity of leaves and stable litter should be collected in readiness for forming beds for the earliest melons and cucumbers. If composed largely of leaves so much the better, as the heat will then remain more steady and lasting. Have the melon and cucumber houses thoroughly cleansed, and every surface well washed with hot limewash, into which a handful of flowers of sulphur has been stirred. As soon as the chrysanthemums have been cleared from the general orchard house, no further time must be lost in making them ready for the trees. The weather has been too mild of late, therefore those who value their crop must be prepared, on the eve of a change, to house the orchard house trees. The most important point in the management of the latest trees is complete rest, not only before, but for some time after they are housed. Even with this careful management the buds are sure to be in advance of those in the open air, and when this stage is reached retarding is at an end, and a suitable temperature must be maintained. Continue to wash, prune, and otherwise cleanse the fruit houses as they become ready, and this work should always be pushed forward as much as possible before the end of the year, as pressure of work gradually increases after this date.

THE GRAPE ROOM.—If the grape room has not been cleansed, and freely ventilated afterwards to expel any moisture, the work should be done at once. Thin-skinned grapes may be cut, as not only will they keep better in bottles but the vines will have a longer rest. The same rule holds good in regard to Lady Downes and other late grapes. A dry, calm day should be chosen for cutting the bunches with all the wood that can be spared, to ensure the stem passing well down into the water. A close watch must be kept at first, as the bunches will absorb water freely, and faulty berries can be easily overlooked in a badly-lighted room.

STRAWBERRIES.—If the first batch has not been placed in position, no further time should be lost. Up to now it has been difficult to keep the temperature down to the proper level, and liberal ventilation has been necessary night and day, but as fresh air from the time the plants are introduced until the fruits begin to swell is important, no harm will have been done. Maintain a genial atmosphere by damping the paths and other available spaces, and keep the roots moist, but not wet. When the plants are lightly plunged in a bed of leaves (and this is an ideal way to start them) they will soon begin to grow, and as soon as the flower spikes are discernible, remove the plants to a shelf close to the glass, and give them a temperature of 50 to 55 degrees. Do not exceed the latter figure until the plants are out of bloom and the fruits set. Introduce fresh batches from the open every fortnight or so, according to demand. If pit accommodation is not available, shelves in peach houses and similar positions may be made use of for starting strawberries. Examine each plant, wash the pots, pick off dead leaves, and see that the drainage is clear. Syringe well underneath the foliage, and fumigate the plants at least once or twice before the flowers open.—F. Jordan, Warter Priory Gardens.

THE FLOWER GARDEN.

SHRUBBERIES.—With but few exceptions deciduous trees and shrubs are now completely devoid of foliage, and the outer portions of the pleasure grounds and shrubberies, where it is not found necessary to clear away leaves until all are fallen, should now be receiving attention. It is very important that sites containing bulbs be taken in hand first, before the bulbs have made sufficient growth to handicap the workers, through fear of damage. It is a well-known fact that clearing away leaves deprives shrubs of much natural food, and although the practice of placing collected leaves in the leaf yard to form leaf-mould is excellent, it is not often that any quantity of the leaf-mould finds its way back to the shrubbery borders, so unless some recompense is made an unsatisfactory condition will result in course of time. This may be overcome by applying a dressing of soil from the refuse heap, or rotten manure, afterwards forking it in. It is not necessary that all borders should be so treated each season, and the work can be determined by the nature of the occupants, the choicer and less vigorous kinds receiving most encouragement. Moving the surface soil by forking amongst the shrubs keeps down weeds, and where only a slight accumulation of leaves occurs these are easily turned under as this work proceeds.

PLANTING.—During open, mild weather planting of all hardy deciduous trees and shrubs and herbaceous plants should be proceeded with, for, although such work is carried out with a certain amount of success until the early spring, no effort should be spared to complete as much as possible of it before the end of the year. Some evergreens, such as rhododendrons, move satisfactorily in the autumn, but it is not advisable, if it can be avoided, to disturb them during the next few weeks, as should a prolonged frost set in they would probably suffer. For several seasons the winters here have been exceptionally mild, and it has been possible to move most evergreen shrubs and trees all the winter through. Nevertheless, it is unwise to take undue risks in this respect, as we may not be far removed from a season of sufficient severity to cut down established evergreens, and in that case recently moved ones would be certain to succumb. The practice of mulching newly-planted subjects with some light, rotten manure should be followed.

COLD FRAMES.—Various subjects connected with the flower garden are occupying cold pits or frames, and require close attention. Generally, these have made good progress this autumn, owing to the favourable weather. It will be necessary when admitting air to act cautiously, avoiding cold draughts. Frames containing the more tender subjects should be well covered up at the least suggestion of frost, as the temperature falls rapidly at this season.—T. B. Field, Wych Cross Place Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

In view of the carnation show, to be held on the following day, there were large exhibits of carnations at the Royal Horticultural Hall on December 2. Besides these, orchids, winter-flowering begonias, and chrysanthemums were the leading floral features, and there was an unusually large number of big exhibits of fruit. The attendance was greater than usual at this time of year.

CARNATIONS.

Cecil F. Raphael, Esq. (gardener, Mr. Grubb), Porter's Park, Shenley, Herts, contributed a magnificent bank of carnations. In the background large stands of Carola, White Wonder, Mary Allwood, etc., served as a good foil to the large collection of the very fragrant Mrs. C. F. Raphael. The flowers throughout were of extra size, and the foliage of the pot plants had that glistening silveriness which tells of high culture, and is a credit to a grower. Mr. A. F. Dutton, Iver, Bucks, set up very many carnations in pots. These were all really good plants of the general saleable size, and were growing in 5in. pots.

Messrs. Young and Co., Cheltenham, included such sterling varieties as Winsor, Sunstar, White Wonder, Rose Dore, and May Day in their excellent collection of fresh carnation blooms. Mr. C. Engelmann, Saffron Walden, Essex, had an immense group of magnificent carnations. The prominent feature was a collection of such vivid crimson and scarlet varieties as Beacon, Commodore, The Herald, Scarlet Carola, and Scarlet Glendale, which glowed with rich colouring and harmonised with the flanking stands of pink, yellow, purple, and white blooms.

Mr. H. Burnett, Guernsey, staged a more sober hued, but a valuable collection, in which the blooms were fresh and fragrant, and borne on the desirable long stout stalks. Messrs. Stuart Low and Co., Bush Hill Park, Enfield, showed an immense collection of cut carnations arranged in a manner which permitted easy inspection. A large central group was composed almost solely of Gorgeous, the variety which recently received an Award of Merit. Besides very many of the standard varieties, there was a large vase of an unnamed seedling, much after the style of May Day, but of a softer shade of colour, which will probably become very popular.

Messrs. Wm. Cutbush and Son, Highgate, made a large display of the brilliant carnation Mrs. Lucy Mackinnon, in their fine group. Their valuable exhibit of winter-flowering begonias included Winter Perfection, Beauty of Hale, Winter Cheer, and a beautiful little batch of varieties of Gloire de Lorraine. Mr. Wm. Lawrensen, Yarm-on-Tees, showed many desirable carnation blooms, notably R. F. Felton, Britannia, Mandarin, Congress, Lady Northcliffe, and similar varieties in fresh and good condition. Messrs. Allwood Bros., Haywards Heath, contributed a collection of fresh and dainty-looking carnations, which included Mary Allwood, Salmon Enchantress, Mrs. T. M. Crook, Scarlet Glow, Calypso, and many other equally good varieties.

GREENHOUSE PLANTS.

Messrs. Sutton and Sons, Reading, staged a large number of plants which illustrated the great improvements which have been effected with Primula obconica. These represnted their grandiflora strain, and included a pure white form, and many shades of colour from blush to deep red. In floriferousness and habit the obconica hybrids closely rival the stellata varieties of P. sinensis.

Messrs. H. B. May and Sons, Edmonton, exhibited cyclamen, Erica hyemalis alba, Begonia Gloire de Lorraine, and, in a corner, many excellent poinsettias. Besides many plants of Poinsettia pulcherrimma with large heads of bright scarlet bracts, there was a group of P. pulcherrimma rosea, which is really of a terra-cotta shade, but pleasing withal. Mr. S. Mortimer, Farnham, showed the pure white stock "All-the-Year-Round."

Messrs. H. Cannell and Sons, Eynsford, made a dazzling display of single zonal pelargoniums in all shades of scarlet and orange, as well as mauve, white, and claret. Along the front many vases of violets supplied the fragrance which the showy pelargoniums lacked. Mr. H. Cole, Swanley, also showed zonal pelargoniums, and included plants of Salvia rutilans, ericas, and small ferns.

Messrs. Jas. Veitch and Sons, Chelsea, filled a length of staging with a splendid collection of winter-flowering begonias, derived from B. socotrana and tuberous varities. The plants now shown evidence an immense improvement on the original crosses. Now the colours are pleasantly varied, and the plants have a splendid habit. At one end of the begonia exhibit there was a large basket of Chrysanthemum Cardinal, the richly-coloured single variety which received an Award of Merit. Mrs. Mullens, Barrow Hills, Long Cross, Surrey, made a charming little display of a few large plants of Begonia Gloire de Lorraine and the white Turnford Hall variety.

CHRYSANTHEMUMS.

A good collection of chrysanthemums was staged by the Manor House Nurseries Company, Cardiff. This was especially strong in single-flowered varieties, and also included good blooms of Mrs. G. Drabble, H. E. Converse, and Manor House Gem. Messrs. W. Wells and Co., Merstham, set up a valuable collection of chrysanthemums. The large-flowered varieties were chiefly Mrs. G. Drabble, James Fraser, Mrs. W. E. Tricker, and Mauve Beauty. Of the singles the most attractive were Mrs. W. Prowting, Brightness, and Lady Furness. At one end there were a couple of vases of Antirrhinum Nelrose, of delightful pale terra-cotta colour.

Colonel the Right Hon. Mark Lockwood, C.V.O., M.P., sent from his gardens at Bishop's Hall, Romford, a great many chrysanthemums, all of the variety Maud Jeffries. These dainty little plants were growing in 5in. pots, and each sturdy specimen bore five or six good-sized pure white blooms, which illustrated the great success which Mr. G. Cradduck attains with this method of culture.

The Misses Price and Fyfe, Lee, gave an attractive display in the annexe, with many decorative chrysanthemums and carnations. Mr. T. Ward, Bishop's Stortford, showed a collection of single chrysanthemums in such varieties as Yellow Perfection, Royalty, J. C. Pillman, and Mrs. A. K. Bowshead. Messrs. Wills and Segar, Onslow Crescent, W., grouped such decorative plants as liliums, Indian azaleas, cyclamen, and lily of the valley.

HARDY PLANTS.

Messrs. Barr and Sons, Covent Garden, displayed many curious and interesting pigmy trees, flanked by Iris tingitana, Cyclamen ibericum in mixed colours, and the Giant Snowdrop (Galanthus Elwesii), besides pans of Roman hyacinths. Messrs. W. Cutbush and Son, Highgate, made an effective show of trees and shrubs arranged on a floor space; a large dormant weeping beech and several standard brooms served to enhance the value of the golden conifers and the berried shrubs.

Mr. L. R. Russell, Richmond, staged seasonable shrubs—chiefly of such berried kinds as Skimmia japonica, Aucuba vera, and Pernettya mucronata. Mr. G. Reuthe, Keston, Kent, had a small collection of uncommon plants, which included Berberis Bealei, Rhododendron Thomsoni grandiflora, and Desfortainea spinosa, as well as a choice set of alpines.

Messrs. Whitelegge and Page, Chislehurst, exhibited many alpines in pots and pans, and a number of conifers, chiefly of dwarf types suitable for rock garden planting. Messrs. T. S. Ware, Lim., Feltham, Middlesex, included charming little plants of Iris stylosa and the albino variety in a valuable collection of border and rockery plants. Plants of Rosmarinus prostrata, in full bloom, illustrated the vagaries of the season.

Mr. Clarence Elliott, Stevenage, continued to show small flowering plants of the rich blue gentian. Various rockery plants—saxifrages, androsaces, and the like—were also shown in small pots, and backed by a row of dwarf conifers. Mr. E. Heathcote, Williton, Somerset, showed ten vases of Violet Princess of Wales, which bore the characteristic large flowers on big stalks. Mr. J. J. Kettle, Corfe Mullen, Dorset, exhibited a splendid collection of double and single violets in many distinct varieties.

ORCHIDS.

Messrs. Stuart Low and Co., Bush Hill Park, Enfield, had several excellent plants of Phalænopsis Rimestadiana and P. amabile, Vanda cœrula of good blue colour, and Houlletia Bricklehurstiana in a noteworthy collection. Messrs. J. Cypher and Sons, Cheltenham, had nothing but cypripediums and masdevallias, but especially the former; they were many and of fine quality. Cypripedium Priam, C. nitens, C. Archimides, C. insigne Sanderæ, and C. Leeanum Clinkaberryanum are the names of only a few of the good sorts on view.

Messrs. J. and A. McBean, Cooksbridge, Sussex, had an attractive arrangement of Lælio-cattleyas, oncidiums, odontiodas, and cypripediums, of which the place of honour was given to the Lælio-cattleya autodoin, which received an Award of Merit. Mr. Harry Dixon, Wandsworth Common, also displayed an attractive collection of orchids.

Messrs. Hassall and Co., Southgate, London, had splendid plants of Cattleya Moira, C. Maggie Raphael, C. Sylvia, and several excellent varieties of Cypripedium insigne. Messrs. Charlesworth and Co., Haywards Heath, showed a magnificent Brasso-cattleya Veitchi, a fine form of Oncidium varicosum, and Odontoglossum crispum Madonna in a small but choice collection.

Messrs. Flory and Black, Slough, displayed such odontoglossums as O. Airworth, O. Perenltum, and O. Harryanio-crispum; with Cypripedium Snowdon and C. Floryi. Messrs. Sander and Co., St. Albans, included a large number of cattleyas and Lælio-cattleyas in a very select collection; of the latter, L.-c. Hon. Mrs. Astor, L.-c. Mauretania, and L.-c. luminosa were especially good. Large sprays of Zygopetalum Mackayi atro-violaceum, and of various oncidiums, hung gracefully over the other plants.

Sir George Holford and Francis Wellesley, Esq., also showed a few orchids, and the former secured a cultural commendation for Lælio-Cattleya Golden Beauty, finely grown by Mr. Alexander.

FRUITS AND VEGETABLES.

The Hon. Vicary Gibbs, Aldenham House, Aldenham, showed that the home-grown apples are equally as attractive as the imported fruits, and of even higher quality. On a whole length of tabling Mr. Edwin Beckett arranged many dishes of excellent apples, interspersed with an occasional dish of grapes, pears, or medlars, all of very tempting appearance. Messrs. H. Cannell and Sons, Eynsford, on the opposite side of the table, displayed a somewhat similar first-rate collection of apples, which, like the foregoing, was characterised by excellent style and high colouring; the golden colour of the Kentish apples was especially telling.

The Agent-General for British Columbia filled the end of the Hall with a monster collection of British Columbian apples. The bulk of the exhibit was in boxes—presumably as imported. There were 300 of them, and

40 varieties were represented. For colour, grading, and packing, it formed a valuable object lesson. Along the front, fruits of the same varieties were set out fancifully in baskets and in dishes. Many of these "foreign" apples were of intense colour, and diffused a strong perfume.

Lord North, Wroxton Abbey, Banbury, contributed a large collection of onions, which the head gardener (Mr. E. R. Janes) arranged with great taste and skill. The large bulbs included the indispensable Ailsa Craig, Cranston's Excelsior, and The Premier. Amongst those with red skins, Sutton's Crimson Globe, Red Italian, and Blood Red were conspicuous.

Messrs. J. Carter and Co., Raynes Park, exhibited a variety of capsicums, which ranged in size from the immense Chinese Giant to the tiny Chameleon, and their shapes and colours were almost as diverse. Messrs. Barr and Sons, Covent Garden, showed the wide variation of the garden kales. The rich green, narrow-leaved Northern Queen, Exquisite Green, and the Tall Scotch Kale, served as foils to those with purple leaves of many shades and the variegated sorts.

CERTIFICATES AND AWARDS.

First-class Certificate.—To Cattleya Maggie Raphael, The Dell variety, from Baron Bruno Shroder (gardener, Mr. Shill), The Dell, Egham.

Award of Merit.—To Odontioda Saturne violaceum, from Mons. H. Graire, Amiens, France; to Odontioda Latona, Goodson's var., from H. S. Goodson, Esq. (gardener, Mr. J. Day), West Hill, Putney; to Lælio-cattleya autodoin, from Messrs. J. and A. MacBean, Cooksbridge; to Cypripedium Goliath, and to C. Strelsa, from W. R. Lee, Esq., Plumpton Hall; to Lælio-cattleya Mrs. Temple, var. Dreadnought, from C. J. Phillips, Esq., The Glebe, Sevenoaks; to Chrysanthemum Maud Jeffries, from Colonel the Right Hon. Mark Lockwood, Bishop's Hall, Romford; to Chrysanthemum Cardinal, from Messrs. J. Veitch and Sons, Chelsea; to Chrysanthemum Commodore, from Mr. T. Stevenson, Woburn Place Gardens, Addlestone; to Violet Kaiser Wilhelm, from Mr. T. Johnson, Shaftesbury; to Begonia Rosalind, from Messrs. J. Veitch and Sons, Chelsea; and to Primula malacoides plena, from Messrs. Bees, Lim., Liverpool.

MEDALS AWARDED.

Gold Hogg.—To the Hon. Vicary Gibbs (gardener, Mr. Edwin Beckett, V.M.H.), Aldenham House, Aldenham, for fruit.

Large Gold.—To the Agent-General for British Columbia, for apples.

Gold.—To Messrs. H. Cannell and Sons, Eynsford, for fruit; to Mr. C. Engelmann, Saffron Walden, for carnations.

Silver-Gilt Knightian. — To Lord North (gardener, Mr. E. H. Janes), Wroxton Abbey, Banbury, for onions.

Silver-Gilt Flora.—To Messrs. Stuart Low and Co., Bush Hill Park, Enfield, for carnations; to Messrs. H. B. May and Co., Upper Edmonton, for poinsettias, etc.; to Messrs. James Veitch and Co., Chelsea, for begonias.

Silver-Gilt Banksian.—To Messrs. Wm. Cutbush and Sons, Highgate, for shrubs, carnations, etc.; to Cecil F. Raphael, Esq. (gardener, Mr. A. Grubb), Porter's Park, Shenley, for Carnations; to Colonel the Right Hon. Mark Lockwood, C.V.O., M.P. (gardener, Mr. A. Cradduck), for chrysanthemums.

Silver Flora.—To Mr. H. Burnett, Guernsey, for carnations; to Messrs. W. Wells and Co., Merstham, for chrysanthemums.

Silver Banksian.—To Messrs. J. Carter and Co., Raynes Park, for capsicums; to Messrs. Sutton and Sons, Reading, for primulas; to Messrs. Young and Co., Cheltenham, for carnations.

Bronze Flora.—To Mr. Lawrensen, Yarm-on-Tees, for carnations.

Bronze Banksian.—To the Misses Price and Fyfe, Lee, for chrysanthemums and carnations; to Mr. L. R. Russell, Richmond, for hardy plants.

SCIENTIFIC COMMITTEE.—November 18.

Present: Mr. E. A. Bowles, M.A., F.L.S. (in the chair), Messrs. J. T. Bennett-Pöe, W. Hales, G. Wilson, A. Worsley, J. Fraser, R. A. Rolfe, H. J. Elwes, A. W. Hill, and F. J. Chittenden (hon. sec.).

CHRYSANTHEMUM - CARNATION GRAFT.—The exhibitor of the flowers from this alleged graft now sent the plants from which they were taken, and careful examination of the lower part of the plant completely failed to reveal the least trace of grafting, while from the base of the stem from which the roots were derived a sucker was developing, clearly belonging to the chrysanthemum. It seems evident that, unknown to the sender, the scion used had rooted and produced a chrysanthemum plant, not perhaps exactly like the original plant, for sporting may occur, and frequently does, while colour varies in shade, at least according to the conditions under which it is produced; but to all intents and purposes this was a chrysanthemum pure and simple.

PELARGONIUM SPORTING.—Mr. A. Worsley showed Pelargonium Firedragon with a large-flowered double sport from it.

LYCORIS STRAMINEA, ETC.—Mr. H. J. Elwes showed a plant thought to be a hybrid, but which Mr. Worsley recognised as Lycoris straminea, a not very well characterised species allied to Lycoris aurea. Mr. Elwes showed also a three-flowered Cypripedium hybrid, C. concolor × C. superbiens = C. Arnoldianum.

HYBRID PELARGONIUMS.—Mr. Fraser continued his remarks upon the history of pelargonium hybrids, dealing with the forms of P. Radula and P. denticulatum.

CATASETUM MACROCARPUM. — Mr. R. A. Rolfe exhibited, from the collection of Mr. G. Rae Fraser, Letchmore Heath, Herts, an inflorescence of male flowers of Catasetum macrocarpum. Female flowers of the same plant have twice been shown before the committee, in October, 1910, and November, 1911, respectively. In the interval the plant has made two futile attempts to flower, but this year it has produced the male inflorescences shown, thus enabling the species to be identified with certainty. Both inflorescences are being preserved at Kew, and the plant is now being presented to the collection there, Mr. Fraser having another good specimen.

CYPRIPEDIUM INSIGNE WITH THREE LIPS.—Mr. Rolfe also exhibited from the collection of Mr. Albert Pam, Wormley Bury, Broxbourne, a twin-flowered scape of Cypripedium insigne, in which the upper flower was normal, but the lower had three lips, representing the condition of the well-known variety Oddity. In this case the two lateral sepals were developed separately, and diverge laterally, and the dorsal sepal is reduced in breadth, while the petals are metamorphosed into lips, which clasp the normal lip.

Dumfries and Galloway Gardeners' Association.

At a meeting of this association, held in the Wesley Hall, Dumfries, Mr. A. Hosking, of the Glasgow and the West of Scotland College of Agriculture, Glasgow, gave a lecture on "Plant Breeding." Mr. S. Arnott presided over a good attendance. Mr. Hosking gave a lucid and highly interesting lecture, which was followed with the closest attention. He discussed the principles of pollination, cross-fertilisation, and hybridising, dealing with these in a full and clear manner, and illustrating the lecture by means of various flowers, such as primulas, begonias, and calceolarias. Improving plants by means of selection was also touched upon, and such points as graft-hybrids and the Mendelian system were also mentioned. The lecture was full of information, and, on the call of the chairman, Mr. Hosking was accorded a cordial vote of thanks.

Perpetual-Flowering Carnation Society.

The winter exhibiton of this society, which was held in the Royal Horticultural Hall on Wednesday, December 3, was particularly successful. Most of the classes were well filled, and the exhibits reached a high standard of excellence. The entries were far larger than on any previous occasion, and amateurs and private growers turned out in force.

GROUPS.

Great interest centred in the competition for the Geo. Monro, jun., Challenge Cup, value 50 guineas, offered by Mr. G. Monro, jun., Covent Garden, for the best twelve vases of carnations, in as many varieties and twenty-five blooms of each variety. There were two competitors, and the cup was won by Mr. C. Engelmann, Saffron Walden, who scored with fine vases of Carola, Enchantress Supreme, Scarlet Carola, Harlequin, Fanny, Sunstar, Snowstorm, Pioneer, Elektra, White Perfection, Triumph, and Lady Northcliffe. The Messrs. Allwood Brothers, Hayward's Heath, staged a fine set, and were awarded a special gold medal as second prize. They used a black velvet background, and came within three points of Mr. Engelmann. Their varieties were White Wonder, Triumph, Mary Allwood, Wivelsfield Wonder, Enchantress Supreme, Rosette, Mrs. C. W. Ward, Empire Day, Mikado, La Rayonnante, Scarlet Glow, and Fairmount.

So far as we could discover there was only one entry in the class for a semi-circular display of cut carnations associated with foliage. Mr. Engelmann secured the first prize, a silver cup, offered by the American Florists, with a glorious exhibit in which huge vases of Sunstar, Carola, Enchantress Supreme, The Herald, Mikado, Pioneer, and Scarlet Glow were conspicuous, with a setting of asparagus and smilax.

Premier award for a group of carnations, as growing, fell to Mr. Holder, Adair Place, Englefield Green, and with this award went the beautiful silver-gilt cup, presented by Lord Howard de Walden. Mr. Holder had a capital display of fine blooms on healthy plants, and he showed popular varieties; Mrs. Bischoffsheim, Warren House, Stanmore, second; and Mr. Burbidge, gardener to Miss G. A. Fenwick, The Croft, Hillmorton, third.

For half a dozen plants of Mr. Engelmann's varieties, Mr. Usher held his own, and won the £4 prize with excellent specimens of Lady Northcliffe, Triumph, and Sunstar; Mr. Holder, gardener to Mrs. Adair, Adair Place, Englefield Green, second. Mr. Usher was also first for two plants of 1912 novelties with Triumph and Lady Northcliffe, and also in another class for a pair of plants, this time with Lady Northcliffe and Regina. Mr. Lloyd and Mr. Holder were second respectively.

OPEN CLASSES.

Premier award for three vases of twelve blooms, each of British novelties, distributed since January 1, 1911, was won by Mr. C. Engelmann, with the yellow Sunstar, the red-striped Fanny, and the rosy Pioneer; Messrs. Stuart Low and Co. second; and Messrs. Wells and Co. third.

The American cup, offered for the best three vases of twelve blooms each of American novelties, distributed since January 1, 1911, was won by Mr. C. Engelmann, Saffron Walden, who showed the bright pink Northport, soft pink Enchantress Supreme, and the pure white Wodenethe in fine condition; Mr. H. T. Mason, Hampton Hill, won the second prize with very bright blooms of Rosette, and he also showed White Wonder and Enchantress Supreme.

There were nine classes for twenty-five blooms of one variety of the various types. In the Enchantress type class the Newport Nurseries Company, Newport, Essex, won the first prize with large, bright blooms of Lady Meyer, and were closely followed by Mr. D. M. Collins, of Heathfield Nurseries, Swanley, with Enchantress. Mr. C. Engelmann led in the class for Mrs. H. Burnett type with

charming blooms of Lucy, and Mr. Collins was again second. Mr. Engelmann also showed the best rose-pink variety, his blooms of Pioneer being especially good; Princess Mary, shown from the Newport Nurseries, was second. Messrs. Stuart Low and Co. put up the brilliant Gorgeous, and won the first prize in the class for the Lawson type; Rosette, as shown by Mr. C. Engelmann, was placed second.

Six of the seven exhibitors showed White Perfection in the white varieties class, where the prizes were won by Mr. H. T. Mason and Messrs. P. Lovell and Co., Manor Nurseries, Worthing, in the order named. There was a greater diversity of scarlets, and here Scarlet Champion, from Messrs. W. Wells and Co., was placed first, followed by Scarlet Glow, from Mr. W. A. Sherwood, Hampton Hill. The Newport Nurseries led with Triumph in the crimson class, closely followed by Mr. C. Engelmann, who showed Carola. Three vases of Mikado, and the rose-coloured Mary Allwood, were the only varieties shown in the class for selfs not eligible in the above list, and Mary Allwood, from Messrs. Allwood Bros., won the first place. The only exhibit in the class for fancies was Sunstar, from Mr. C. Engelmann, and it received the first prize.

The best vase of twelve blooms of any registered variety not in commerce was that of Champion, a fragrant, bright scarlet crimson bloom, from Messrs. W. Wells and Co.; Gorgeous, from Messrs. Stuart Low and Co., being a good second.

The competition generally was not great in the classes for single vases of various varieties. Sir R. Baker won Messrs. Stuart Low and Co.'s cup with fine blooms of such varieties as Fairmount, Lady Alington, and Mrs. L. M. Crook, and also secured the silver challenge cup presented by Mrs. Norman for five blooms of British-raised seedlings. The first prize for Mr. Burnett's novelties was won by Capt. Weiner, who had splendid blooms of Mrs. C. F. Raphael, Calypso, and Mandarin. Lord Burnham (gardener, Mr. J. Johnson), Hall Barn, Beaconsfield, won the challenge cup offered by Messrs. W. Wells and Co. with Whitehouse and Woodnethe, and also the first prize given by Messrs. Young and Co. with six good blooms of Lady Audrey Neild. The class for twelve blooms of Messrs. Young and Co.'s novelties was won by Mr. Usher.

AMATEURS.

In the amateurs' section five flowers were required in a series of classes for varieties of a given colour. The competition was fairly keen in most classes. For a vase of a variety of the Enchantress type, Mr. H. Lloyd, gardener to Captain Weiner, Ewell Castle, Ewell, led with R. F. Felton; and Mr. W. Reid, gardener to the Countess of Derby, Cowarth Park, Sunningdale, came second with Enchantress.

In the Messrs. Burnett colour class Mr. J. Shaw, gardener to Oswald Hedley, Esq., Dilston Hall, Corbridge, led with Baroness de Brienen in fine form; Mr. Cullwick, gardener to Captain D. Macpherson, Westlaker, second. Mr. Johnson, gardener to Lord Burnham, Hall Barn, Beaconsfield, led in the rose-pink section with Rose Pink Enchantress; and Mr. W. G. Dance, gardener to J. S. Cross, Esq., Calthorpe Towers, Rugby, second.

Mr. A. E. Usher, Ranston Gardens, Blandford, scored with Rosette in the Lawson class, and Mr. Johnson came second.

For a white variety Mr. W. J. Reid led with White Wonder, and Mr. Usher came second with the same variety. Mr. H. Smith, gardener to Brodie Henderson, Esq., Elphine House, Little Berkhampsted, scored for a scarlet variety with Scarlet Glow; Mr. Usher second. For a crimson variety, Mr. Jackson, Danehurst, Epsom, scored with fine specimens of Carola; and Mr. Lloyd came second with this variety among nine competitors—indeed, there were eight or ten competitors in nearly all these classes. For any other colour than specified, Mr. Dance came to the front with Mikado, and Mrs. F. Norman, Moor Place, Much Hadham, second. In the fancy class Mr. Usher scored with Benona, and Mr. Lawrence, Rodstone, came second. Mr. Usher staged the finest five flowers of the beautiful Mrs. A. F. Dutton.

AMATEURS—SECOND DIVISION.

An interesting division is for amateur members who only employ a part-time gardener, and for such members, resident upwards of 50 miles from London, the blooms were staged by the society's officials. The classes were for three blooms of a variety, and the colours followed the arrangements in previous divisions. The chief first prize-winners and their varieties were Mr. G. H. Lawrence, Godstone, with Enchantress; Mr. A. Whitworth, Datchet, with Mrs. A. F. Dutton; Mr. T. C. Loosemore, Weymouth, with Mrs. C. W. Ward; Mr. Lawrence, with White Wonder; Mr. Loosemore, with Scarlet Glow, and also with Triumph; Mr. Lawrence and Mr. Loosemore equal for a self coloured variety with Mikado and Mary Allwood respectively. For a mixed vase of six flowers Mr. A. J. Digby, Kortleton Avenue, Weymouth, led.

In the division for those who had not previously won more than two first prizes, the chief winners were Mr. G. Pain, Hornsey; Mr. F. Ballard, Barcombe, Lewes; Mr. J. Mackenzie, Shooter's Hill; and Mr. L. E. Lacey, Hillcroft, Farnborough.

Lloyd), Ewell Castle, Surrey, a good second.

Mr. R. F. Felton, of Hanover Square, London, who used Mrs. Burnett carnations, sprays of Asparagus plumosus and of Pittosporum Colensoi, had the best bouquet; Mrs. Adair, Adair Place, Englefield Green, being second with a neat arrangement.

No fewer than twelve exhibitors competed in the vase class, and all the arrangements were of more than average merit. Mr. Joseph Shaw, gardener to O. W. Hedley, Esq., Dilston Hall, Corbridge-on-Tyne, won the first prize, rather for the excellence of his blooms than for taste in arrangement; the second prize vase, by Mr. T. F. Stannett, gardener to Frank May, Esq., Houndswood, Radlett, was more attractive.

NEW VARIETIES.

Awards of Merit were granted to the American varieties, Enchantress Supreme, Gorgeous, and Champion.

Similar awards were made to English varieties; Lady Fuller, 84 points, from Mr. C. Wall, Melrose Nursery, Bath; Queen Alexandra, 77 points, from Messrs. G. Clarke and Co., Leighton Buzzard; Cinderella, 75 points, from Messrs. George Fairbairn and Sons, Carlisle; Pioneer, 75 points, from Mr. C. Engelmann.

FIRST PRIZE GROUP OF PERPETUAL CARNATIONS.

Set up at the Royal Horticultural Hall on December 3, by Mr. C. Engelmann, Saffron Walden, who won, with it, the Fifty-guinea Silver-gilt Cup, presented by Mr. George Monro, jun., of Covent Garden.

FLORAL DECORATIONS.

First prize for a table decoration of perpetual carnations was won by Mrs. A. R. Bide, Guildford Road, Farnham, with a pleasing design in a variety very like Mary Allwood; Mrs. A. Robinson, Norhyrst, Carshalton, second, with a blush variety of the May Day type, thoroughly well arranged down the centre, but weak at the corners. Messrs. R. Felton and Sons, Hanover Square, third with pale salmon-pink flowers.

In another class for table decorations there were seven competitors. Mr. Usher, Ranston Gardens, came first with a light arrangement of Enchantress; Mr. Holder, Adair Place Gardens, second; and Mrs. A. R. Bide, Farnham, third.

The baskets of carnations were very charming, and the leading award went to Mr. R. F. Felton, who used the yellow Sunstar to great advantage; Mrs. Adair had a heavier arrangement of mixed colours. Mr. Felton also won with three ladies' sprays, where he was very closely followed by the Countess of Derby (gardener, Mr. W. J. Reed). The gentlemen's buttonhole flowers were also of great merit, and here S. F. Jackson, Esq., Danehurst, Epsom, won the premier prize, and Captain Weiner (gardener, Mr. H. S.

NON-COMPETITIVE.

All of the trade groups of carnations, and some of the general exhibits, to which attention is drawn in our report of the Royal Horticultural Society's show on Tuesday, were retained for the carnation show, and among these were displays by Messrs. Young and Co., Mr. H. Burnett, Messrs. Wells and Co., Messrs. Stuart Low and Co., Mr. A. F. Dutton, and Mr. Wm. Lawrenson. Messrs. Allwood Bros., Haywards Heath, added largely to their exhibit, and made a central feature of the beautiful Mary Allwood. Triumph, Wivelsfield White; Mrs. F. M. Crook, and Yellowstone were also shown in quantity. Messrs. Wm. Cutbush and Son, Highgate, re-arranged their exhibit of carnations which they showed on the previous day, making a beautiful arrangement of fresh blooms. Messrs. Geo. Fairbairn and Sons, Carlisle, showed their new Cinderella in a small collection.

Mr. C. Engelmann allowed most of his monster collection to remain, replacing the few fading blooms, and arraning an additional group on a floor space.

MEDALS AWARDED.

Large Gold.—To Mr. C. Engelmann, Saffron Walden.

Gold.—To Messrs. Stuart Low and Co., Enfield; to Messrs. Allwood Brothers, Haywards Heath; to C. F. Raphael, Esq. (gardener, Mr. Grubb), Porters Park, Shenley.

Silver-gilt.—To Messrs. Young and Co., Cheltenham.

Silver.—To Mr. H. Burnett, Guernsey; to Messrs. W. Cutbush and Son, Highgate; and to Messrs. George Clarke and Co., Leighton Buzzard.

Bronze.—To Mr. W. Lawrensen, Yarm-on-Tees.

National Dahlia Society.

The annual general meeting of this society was held at the Hotel Windsor on Monday, December 1. Mr. G. Gordon, V.M.H., the president, in the chair, and about thirty members present. The report and balance-sheet were adjourned until the next meeting; the financial statement, as read, was satisfactory, the society being able to meet all its obligations. Mr. J. A. Jarratt, Anerley, proposed a vote of thanks to the retiring officers, and this was seconded by Mr. W. J. Cramp, Streatham.

Mr. G. Gordon, V.M.H., was re-elected president unanimously; with Mr. J. Green as treasurer, and Mr. J. Cheal, V.M.H., chairman of committee. Mr. R. Cory was elected a vice-president; and Mr. J. B. Riding retains the secretaryship; while Mr. J. Woolman, Birmingham, Mr. J. A. Jarratt, and Mr. W. J. Cramp were elected to serve on the committee. The Publication Committee is formed by Mr. C. H. Curtis and the officers ex-officio. The members of the Classification Committee elected were Messrs. E. Doncaster, H. Shoesmith, S. Mortimer, J. T. West, J. Stredwick, and the officers ex-officio. Mr. G. L. Caselton is again hon. show superintendent; and the hon. auditor is Mr. G. Davidson.

A hearty vote of thanks was accorded to Mr. Gordon for presiding.

Woolton.

NOVEMBER 19.

This society held its fifteenth exhibition in the Church Hall. The plants, both trained and staked, were staged on the platform, running the full width of the hall, and made a most effective display. Possibly the plants created a record for quality and training, and the chief winners in this section were: Mr. J. Penlington, gardener to Alfred Fletcher, Esq., who led for three large-flowering; one Japanese, and one incurved; Mr. R. Hitchman, gardener to Mrs. Schintz; Mr. W. Wilson, gardener to W. Cunningham, Esq.

In the other plant classes Mr. G. Hodnett, gardener to A. G. Dent, Esq., palms; Mr. G. Haigh, gardener to Sir W. H. Tate, orchids, cyclamen, and lily of the valley; Mr. J. Litton, gardener to Miss Young, hyacinths; Mr. G. Lowe, gardener to Colonel J. P. Reynolds, foliage plants; Mr. J. Hunter, gardener to R. Gladstone, Esq., salvias; Mr. C. Price, gardener to Mrs. Clarke, cypripediums; and Mr. J. Stoney, gardener to Lieut.-Colonel J. B. Gaskell, begonias, were the chief prizewinners.

Cut flowers were up to the average in size, and Mr. G. Haigh, Mr. G. Lowe, and Mr. H. Howard, gardener to Alderman A. S. Mather, were first respectively for twenty-four, eighteen, and twelve Japanese blooms; Messrs. J. Stoney and H. Howard took the lead for eighteen and twelve incurved respectively; and Mr. Stoney's was an excellent set.

In the class for nine vases of single varieties, nine blooms in each vase, there was a keen competition, Mr. Hitchman securing the coveted position; some of the flowers exceeded seven inches in diameter, were of fine colour, and remarkably good shape. For six vases, six blooms in each vase, Mr. Haigh proved the winner. For four vases of incurved blooms, three in each vase, Mr. Haigh led with good examples, and also scored for six vases, four stems in each vase, and four blooms on each stem, the whole arranged for effect, but there was room for improvement in effective staging.

Two classes are allotted to under-gardeners, one for a bouquet and one for three sprays and three buttonhole flowers. That there is a healthy interest in this section may be gathered from the fact that nine bouquets and fourteen sprays and buttonholes were the result, and every exhibit was worthy of an award. Mr. G. Cowley, Highfield Gardens, led in the first-named class, and Mr. R. Hosker, Dove Park Gardens, in the latter.

Grapes were not quite up to the usual standard. Mr. W. Wilson won for two bunches of white grapes with Muscat of Alexandria, and Mr. J. McCole scored for black grapes with Alicante.

Mr. C. Price secured the leading award for a collection of vegetables, Mr. J. Gore scored for the farmers, and Mr. J. Radley for the cottagers in this division, and each received a silver challenge cup with the first prize.

Dundee Chrysanthemum Society.

The annual autumn show held by this society was opened by Lord Provost Urquhart, in the Kinnaird Hall, on November 21. The president, Mr. Walker S. Melville, presided at the opening ceremony, and, as has been his custom in the past, took a full share in the work of organisation, while the secretarial duties performed by Mr. W. F. Hill gave every satisfaction, and Mr. Alex Crighton deserves praise for the effective way in which the exhibits were arranged.

The Corporation Cup, given for thirty-six blooms in twelve vases, was won by Mr. Alex Duncan, Carbet Castle Gardens, who showed a very even lot of superior flowers of Hon. Mrs. Lopes, F. Penford, W. S. Thorn, Master James, Lady Talbot, J. H. Silsbury, F. S. Vallis, etc. Mr. J. Reid, Esk Park, Brechin, was second, his outstanding flowers being Fred Green, J. H. Silsbury, and Mdme. R. Cadbury. Mr. D. Keillor, Seaborne Gardens, was first for eight vases (twenty-four blooms), having grand flowers of F. S. Vallis, W. Mease, F. Chandler, Reginald Vallis, B. Pulling, Mary Poulton, and F. Rowe; Mr. R. McNaughton, Battleby, Redgorton, Perthshire, was second; and Mr. George Mollison, Territ, Cupar, Fife, third.

Mr. McNaughton scored well for the six vases and the Smieton memorial medal, which now becomes his property. His blooms of Queen Mary were a marvel, and certainly deserved the honour of being the best flowers in the show. Other varieties well shown were Mrs. A. T. Miller, Mary Poulton, W. S. Thorn, Hon. Mrs. Lopes, and His Majesty; Mr. David Keillor was second. Mr. T. C. Brown was first for four vases, Japanese; and Mr. James Hughes, Erigmore, Birnam, was second. Mr. Alex. Duncan was first for four vases, Japanese incurved, his flowers of Lady Lechworth, W. S. Thorn, and Elinor Duchess of Northumberland being particularly fine. Messrs. Keillor and John Fraser, Lochie, were the runners-up, as named. Messrs. T. C. Brown, Jas. Hughes, and John Fraser scored, as named, for two vases (six Japanese blooms).

For nine vases of decorative varieties, not disbudded, Ms. George Scott, Seathwood, Mr. James Beats, Binrock, and Mr. John Fraser, Lochie, won, as named, with creditable lots. For nine vases of singles, not disbudded, Messrs. J. Beats, A. Duncan, and G. Scott were the winners. For one vase of singles, Mr. T. C. Brown, Mr. D. Keillor, and Mr. James Bethel won, as named; while for one vase of singles, disbudded, Mr. Jas. Beats was the winner; and for one vase of chrysanthemums, arranged for effect, Mr. G. Scott was to the front.

Messrs. Scott, Beats, and Fraser scored, as named, for dinner-table decoration; and Mr. Scott, Mr. Beats, and Mr. W. Cook scored, as named, for a shower bouquet and a basket of blooms arranged for effect. For two dress sprays and two buttonhole bouquets, Mr. I. Margach was first, Mr. Jas. Bethel second, and Mr. Geo. Scott third.

In the plant section, Mr. Geo. Scott was first for nine plants in 6in. pots, and magnificent specimens they were. Mr. Jas. Beats was second, and Mr. John Fraser third with highly creditable examples.

Messrs. Beats and Scott scored, as named, for three pots of singles and three pots of decorative varieties, not disbudded. Mr. A. Duncan was first for Primula obconica and Begonia Gloire de Lorraine; and Mr. Geo. Scott first for Primula sinensis. Mr. Jas. Staward, St. Fort, was first for cyclamen. Mr. Jas. Bethel was first for a collection of vegetables, with Mr. James Staward second.

In the amateurs' section vegetables were, as usual, very numerous, and were highly creditable. Mr. D. Orchiston was first for a collection of vegetables, and also for leeks and Brussels sprouts. Mr. D. Smith proved a good runner-up, and scored first for red onions and celery. Messrs. Jas. Clark, Wm. Davidson, Wm. Robertson, Wm. Dodds, John Denholm, and John Keill were the most successful competitors met with in the pot plant section, always so popular with Dundee amateurs. In the cut flower section, open to amateurs only, in addition to winning the Watson challenge cup for twelve blooms, Mr. John Denholm, Blackness Road, annexed firsts for three vases of nine blooms, one vase of undisbudded and one vase of disbudded flowers, and for a vase of singles.

Trade exhibits were few, and, had it not been for the bright table of Begonia Gloire de Lorraine and single chrysanthemums set up by Messrs. Croll and Sons, the magnificent display of imported fruits and vegetables set up by Messrs. Harley and Sons, and the table decorations displayed by Mr. Arthur Edwards, Notts, one would have thought that the nurserymen and florists had gone on strike.

BARR'S SPECIAL BULB PLANTER

Rd. 548001.

Specially designed for planting Daffodils and other bulbs in grass. This tool cuts and lifts a clean circular piece of turf, which is released from the cup when the second hole is made, and lies ready at hand to fill in the holes when the bulbs have been put in, it being only necessary to remove a little of the soil from the bottom of the sod. By its use a large quantity of bulbs may be planted in a very short time, and without the least disturbance of the sward. The cup is manufactured from high-class hardened steel, and always carries a keen cutting edge. 10s. 6d. each.—BARR and SONS, 11, 12, and 13, King Street, Covent Garden London.

ANSWERS TO CORRESPONDENTS.

Specimens of plants, flowers, and fruits for naming, or opinion, should be sent to the Editor of THE GARDENERS' MAGAZINE, 2, Adelaide Road, Brentford, Middlesex, and as early in the week as possible. All parcels must be sufficiently prepaid.

SCARLET OAK.—I. C., Bath: Information was recently asked and given respecting the production of sprays of scarlet oak foliage for decorative purposes. I would be glad if you can tell me the correct name of the scarlet oak, and whether the vivid colouration referred to has anything to do with sunshine, soil, or pruning. We have two scarlet oaks here, and in neither case does the foliage ever become anything more than a dull reddish-yellow.—There are several oaks which have their leaves coloured red or scarlet during the autumn, and the best of these are Quercus coccinea, Q. prinoides, and Q. rubra. The latter is popularly known as the Red Oak, but Q. coccinea or its varieties are often grown for the purpose of producing sprays of richly-hued foliage. One of the finest forms of Q. coccinea is Knap Hill Scarlet, which, besides assuming a brilliant colour, is notable for the length of time it retains its leaves, these often remaining on the boughs up to Christmas.

LIME DRESSING FOR LIGHT SOIL.—G. G., Enfield: Will you kindly tell me what quantity of quicklime I should use per square yard for dressing a medium or moderately light soil?—If the land has been well manured over a series of years, and therefore contains a good deal of humus, a good dressing of lime will prove useful in neutralising organic acids and setting free much of the plant food latent in the soil. Half a bushel of quicklime per rod is a fairly good dressing, but this amount may be increased by one-half if the soil naturally lacks lime. If you are at once working the soil it will be a better plan to use basic slag now, and then give a half-dressing of lime in the spring, a few weeks before sowing or planting. Lime is best used in a fresh state, and should be placed on the land in small heaps just as it comes fresh from the kiln. Cover these heaps with soil, and when the lime is slaked spread it evenly and lightly dig or fork it in.

POTATO BUTLER'S DEFIANCE. — A Grimsby correspondent is seeking for information concerning a potato given him under the name of Butler's Defiance. He cannot find such a name in any catalogue to which he has access. The tuber has a very rough skin, the stems are long, thin, and wiry, and the flowers pure white. Any information our readers can supply concerning the origin of this variety will be appreciated. We find no mention of such a name in the audit of the great potato show of 1905.

SPECIMEN COLEUS.—Tango, Essex: Could you inform me, through your columns, how I should proceed with coleuses? I wish to grow a few large specimens for exhibition purposes next year, and want to have them as well furnished and brightly coloured as possible.—The success achieved with coleuses will depend chiefly upon the conveniences at command and attention to a few simple details, for, after all, coleuses are among the easiest of plants to cultivate. As soon as possible in the New Year insert cuttings in tiny pots of sandy soil, and place them in a case where a temperature of 55 to 60 degrees is maintained. As soon as rooted, remove from the case, and in a few days pot into large 60-sized pots, using a compost of rich sandy loam. Pinch out the growing points quite early, and repeat this operation during spring and early summer as soon as each growth has made two or three pairs of good leaves. You will soon learn, under the conditions provided, how long a period should elapse between pinching and the development of new growths, and thus you will be able to time the specimens for the exhibition. A 24-sized pot will generally be large enough, but 16-size may be used if the plants develop freely, for, while free growth is essential during all the earlier stages, care must be taken to colour the foliage well, and this can only be accomplished if the plants are grown in a light and bright position near the glass, and the pots become thoroughly well filled with roots some time before the specimens are needed for exhibition, or the decoration of the conservatory. Feeding is rarely necessary until the final pots are packed with roots; then liquid manure and clear water must be given freely or the leaves will fall. We may add that the rather severe pinching suggested is for the purpose of securing large, bushy, and flattish specimens; less pinching is needed for pyramidal plants. In both cases some amount of training must be done, and at all times the plants must be kept clean.

GOLD RUST ON ROSES.—T. B., Stranraer: My roses have gold rust on the leaves, and though I have sprayed during the past summer with Bordeaux mixture, this has had no effect whatever upon the disease. Can you recommend any other spraying mixture which would help me, or should I treat the ground beneath the plants in any particular way? The leaves are now turning brown and falling.—In the absence of specimens we cannot determine the disease from which your roses are suffering, but probably it is the Rose Rust (Phragmidium subcorticatum). In certain seasons and districts this is a troublesome pest, and no means should be spared to eradicate it. We have quite recently referred to the disease in this column, but we may again point out that the winter spores appear on the leaves in the form of tiny black points, and these spores rest during the winter, commence growth again in spring, and produce secondary spores, which speedily infect the young growths and leaves of the roses, and so give rise to the yellow or orange coloured rust seen in the summer. From this you will gather that it is of the utmost importance no leaves or broken growths should remain on the soil, but should be gathered and burned promptly, because, if this is done, and all prunings are burned in the spring, the best means of checking the spread of the disease will have been taken. The fungus does not rest in the wood of the rose but broken shoots carry leaves to the ground. If the summer form of the disease has attacked the growths, treat the affected portions with methylated spirit and water, mixed in equal proportions. Just before the leaves expand next season spray the bushes with sulphide of potassium solution. It may be as well to follow with other sprayings as the leaves advance, but half an ounce of sulphide of potassium to a gallon of water will be strong enough at first, though later on, as the leaves become firmer, 2oz. in 3 galls. of water will be a better fungicide.

NAMES OF PLANTS.

F. F., Ilfracombe.—1, Pittosporum Tobira.

J. P., Bury St. Edmunds.—The leaves of Artemisia lactiflora.

S. A. N., Chislehurst. — 1, Eranthemum pulchellum; 2, Begonia socotrana; 3, Pelargonium denticulatum.

A. J. W., Ealing.—1, Abies Nordmanniana; 2, Choisya ternata; 3, Caryopteris mastacantha; 4, Linum trigynum.

H. C. H., Newcastle.—1, Cupressus Lawsoniana; 2, Iris speciosa; 3, Juniperus chinensis; 4, Sequoia sempervirens; 5, Erica gracilis; 6, Thryrsacanthus rutilans.

NAMES OF FRUITS.

C. L. D., Exeter.—1, Claygate Pearmain; 2, probably Newton Wonder.

E. M. E., Bushey.—1, Bismarck; 2, Ribston Pippin; 3, not recognised.

A. H., Salisbury.—1, Smart's Prince Arthur; 2, Dumelow's Seedling; 3, Lane's Prince Albert; 4, King of the Pippins; 5, Twenty-ounce—a fine set of specimens.

H. F., Grimsby.—1, Gravenstein; 2, London Pippin; 3, probably Golden Noble—a rather tall example; 4, Adam's Pearmain; 5, King of the Pippins; 6, not recognised, probably a local seedling.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

The Effects of Grafting.

Grafting is an operation by which a portion of a plant of one species or variety is inserted into or upon another and different one, and this is carried out on a very large scale for more reasons than one. In the first place, obviously a cutting or scion so introduced is provided at once with a root system by which, if the growths of the stock or rooted plants are suppressed, a far more rapid development is secured, and both fruiting and flowering is attained, it may be, in a single season, instead of a considerably longer period. A weakly-growing plant may also greatly benefit by its association with a robust one, and, in addition to this, grafting affords a means of propagating a rarity to any desired extent much more quickly than by cuttings, since simple buds will generally suffice, for budding is a form of grafting. Furthermore, while the progeny from seeds is often unreliable, the graft, as a rule, produces a perfectly true representation of its parental type. To the thoughtful mind, however, the fact that such association can be at all relied upon to cause no difference in the graft or scion, as it is termed, is a mystery. Every plant normally develops a root system which penetrates the soil, and selects therefrom the earthly salts necessary for its nutrition and the formation, when they reach the foliage, of the structural and other materials required for the development of that particular plant. With the water, also collected by the root system, the sap is formed and transmitted to the leaves, in which, under the influence of the sunlight, and in conjunction with the carbonic acid derived from the atmosphere, it is used by the wonderful leaf-green chlorophyl grains to create the materials aforesaid. With a graft, however, there is no direct connection with a root system of its own, but with an alien one which will have only collected the earthly salts proper to its own particular needs. Hence it is clear that at the point of junction the inserted bud or scion must presumably exercise a process of selection and exclusion as regards the material supplied to it by the alien stock and roots. On the other hand, as regards the stock, as all its own buds and shoots are presumably suppressed by the cultivator in favour of the scion, it is eventually the foliage of this latter alone which subsequently contributes its alien material to the development and strengthening of the stock and its root system below the point of junction. Thus there must be a reverse selective and exclusive action on the part of the stock itself, since, if any foliar growth is accidentally permitted on the trunk or from the root (in the form of suckers), these, as a rule, are unaffected by the graft, and exactly resemble those peculiar to the stock. These phenomena are so general

MR. JAMES CORNFORD.

in their occurrence that exceptions are very rare. In recent times, however, a suspicion has arisen, particularly in the case of grafted fruit trees, that both flavour and shape, and even general appearance, may be affected when fine fruits are grafted on common and inferior ones, and in the case we have in view as we write, it is fairly demonstrated that even poisons may be able to run the gauntlet, so to speak, of the selective cells at the point of junction, and, by analysis, give evidence of their presence in an otherwise innocent graft. In the "Revue Horticole" some well-authenticated cases are recorded in connection with a large number of experiments made in this particular direction. In the Solanum group, for instance, we have examples of the innocuous and nutritious potato and tomato, on the one hand, and of the deadly belladonna on the other, and as these belong to the self-same order it has been found possible to effect grafts between them. As the result of grafting the tomato on the belladonna it has been conclusively proved that the tomato fruit produced contained an appreciable quantity of an alkaloid so closely akin to atropine, the deadly principle of the stock plant, that it produced the same pathological symptoms of poisoning. Atropine, on the other hand, has also been found present in potato tubers derived from a potato stock, on which was grafted Datura Stramonium. From these results, and many others, it is therefore clear that the point of graft junction does not represent an absolute bar to stock influences on the graft growths, on the one hand, or of the grafts on the products of the stock or its root system on the other.

Mr. James Cornford, for 30 years head gardener to Colonel and Mrs. Powell Cotton, at Quex Park, Birchington, Kent, occupies a position in the front rank of cultivators, but he is at all times prompt to inform those who congratulate him upon his successes, that these would not be so numerous were it not for the very generous manner in which his employers deal with their gardens. Mr. Cornford's experience before coming to Quex Park was gained in such well-known gardens as those of Shoreham Place and Chatsworth. Since coming to Quex Park he has supervised a great enlargement of the pleasure grounds and created a new kitchen garden, 3½ acres in extent, enclosed by walls 12ft. high, all wired for fruit trees, and well furnished with peaches, nectarines, and pears. Mr. Cornford has been a most successful exhibitor, and among the thousand and more prizes he has won, over five hundred have been for chrysanthemums, including five silver cups (one valued at £50), one gold medal, and many silver medals. He has won many prizes at exhibitions of the Royal Horticultural Society, including two Hogg Memorial Medals, two silver medals, and a cup for hardy fruits. Mr. Cornford has been no less successful with vegetables, but, better even than his splendid list of prizes, the fine condition of the gardens and grounds of Quex Park testifies to his skill as a cultivator and organiser.

A Suggestion for the Royal Horticultural Society.—Mr. Percy A. Cragg, of the Merivale Nurseries, Heston, has no faith in criticisms which fail to include suggestions for improvement, and so, feeling that the Royal Horticultural Society does little for the advantage of market growers, he suggests that the Council be urged "to erect on an open spot two blocks of houses built exactly alike, and on

similar lines to a nursery. Various systems of heating could be tried, for instance pipes on ground level against those overhead; a few large pipes against more smaller ones; forced circulation against normal; sectional against tubular boilers; various settings of the boilers themselves; oil and gas against coke and coal; forced draught, etc., etc. The possibilities are infinite, and economy is sure to result if the trials are well carried out. Each year it becomes a necessity to produce goods more economically, so economy must be sought for in every way." We hope Mr. Cragg has also sent this suggestion, in writing, to the R.H.S. Council.

The "Orchid Review."—Our esteemed contemporary, the "Orchid Review," has just completed its twenty-first volume, and we find the title page for 1913 carries the inscription: To Sir Frederick W. Moore, M.A., F.L.S., Keeper of the Royal Botanic Garden, Glasnevin, one of our most enthusiastic and most successful cultivators, the twenty-first volume of the "Orchid Review" is cordially dedicated.

Mr. J. C. Newsham, for several years the successful master at the School of Agriculture and Horticulture, Old Basing, Hampshire, has been appointed Principal of the New Farm Institute, now established at Usk, in Monmouthshire. Mr. Newsham takes up his new duties directly after Christmas, and we heartily congratulate him upon well-deserved promotion.

Exhibition of Bottled Fruits at Shrewsbury, 1914. — The Royal Agricultural Society of England are proposing to offer prizes for bottled fruits in connection with their show to be held at Shrewsbury in 1914. The classification has been arranged so as to include competition by both the large grower and the smallholder. The fruit must have been grown in the United Kingdom, and the exhibitor must be the grower and bottler and bona fide owner of the fruit. Further particulars will be supplied on application to Thomas McRow, secretary, 16, Bedford Square, London, W.C.

Apples in Grass Orchards.—In the most emphatic language, we have protested time after time against allowing grass to grow right up to the stems of young fruit trees. Experiments have proved that trees with their roots grassed over, particularly in their earlier years, lack the vigour of those around which the soil is cultivated. Mr. G. H. Hollingworth, the Gloucestershire County Instructor in Horticulture, has written a pamphlet, published by the Gloucestershire Education Committee, and free on application to the County Education Office, Shire Hall, Gloucester, entitled "Apples in Grass Orchards; The Treatment of Young Trees." The author points out that common causes of failure are: (1) Neglect of early pruning; (2) allowing grass to grow over the roots of newly-planted trees; (3) damage by grazing animals, through inadequate fencing; (4) bad staking and rubbing of trees on stakes through insecure tying; (5) and selecting unsuitable sites, and planting in poor or badly-drained soil. Mr. Hollingworth rightly points out that every cultivator could, by the display of ordinary and reasonable care, avoid all these mistakes. But it is to the mistake of grassing young trees we would especially point, because Mr. Hollingworth, by measurements and by illustrations from photographs, shows the evils of grassing, and the value of cultivation. A staff, 4 inches in circumference, was placed beside each tree stem previous to taking the photographs, and serves as a basis of comparison. The figures are striking. In Mr. G. E. Lloyd Baker's estate at Hardwicke, cider apples and perry pears were planted in December, 1908, and, for the purpose of experiment, the turf was returned over the roots of a number of trees. The girths of the stems of trees grassed over are $3\frac{1}{2}$, $3\frac{3}{4}$, $3\frac{1}{4}$, and $4\frac{1}{2}$ inches respectively, while corresponding trees of the same varieties, practically identical at planting time, and hoed around twice a year since, have a stem girth at 4ft. from the ground of $5\frac{1}{2}$, $5\frac{1}{4}$, 5, $5\frac{1}{4}$, and $6\frac{1}{2}$ inches respectively, or a gain in girth of from $1\frac{1}{4}$ to $2\frac{1}{4}$ inches. The illustrations show conclusively that the vigour of the trees is in accord with the girth of their stems.

Saturday Half-holiday at the Royal Nurseries, Slough.—We learn with great pleasure that employees at the Royal Nurseries, Slough, have recently been granted the Saturday afternoon holiday. The men are so delighted with Mr. Arthur Turner's kindness that they have made special arrangements for keeping the nursery open, so that customers and visitors will always find one foreman and one deputy foreman to receive them on Saturday afternoon on behalf of the firm of Mr. Charles Turner.

A Register of Hybrid Orchids.—The President and Council of the Royal Horticultural Society, acting on the recommendation of the Orchid Committee, have decided to establish a Register of Hybrid Orchids at Vincent Square. Mr. R. A. Rolfe, A.L.S., of Kew, has been appointed Recorder. The register will include all known orchids. The President and Council accordingly invite orchid raisers and growers, amateur and professional, to bring their hybrids, when in flower for the first time (even though they may not then be sufficiently developed to enter for award), and to enter the name and parentage of the plant, together with the exhibitor's name and address, on a registration form, which can be obtained from the R.H.S. Office, Vincent Square, S.W. The registration form should be sent with the plant, and it will be placed before the Orchid Committee, who, after satisfying themselves that the name is in order, will enter it on the Register. Once so recorded the name must be recognised for all crosses of similar parentage when subsequently shown, unless valid reason can be otherwise produced.

The "City Diary" for 1914 reminds us that we are nearing the end of 1913, and engagements for the coming year are already accumulating so fast that a diary is essential, "lest we forget." This new issue, from the office of the "City Press," 148 and 149, Aldersgate Street, contains a vast amount of information concerning the City of London, its government, its schools and banks, churches, parishes, and hospitals, its companies, and its courts of justice. Besides all this, there is useful postal information, and an almanac. The diary proper has a week at an opening, and the pages are interleaved with blotting paper. The cost of the "City Diary" is 1s.

British Forestry.—Some little progress is being made in connection with forestry in the United Kingdom, but so much remains to be done that, unless public opinion is turned in the direction of this industry, and its needs and importance, our children's children may rise up to curse our apathy. Sir William Schlich, Professor of Forestry at Oxford, quite recently pointed out that, while we produced about three million tons of timber, we imported ten million tons, about a quarter of which came from our colonies. In his opinion, 90 per cent. of the timber needed for building purposes could be grown at home, provided steps were taken at once to convert about a third of the available mountain and heath lands to forestry. It is stated that we spend £30,000,000 a year on imported timber and wood pulp, most of which might be produced at home if waste lands were suitably planted.

Dates of Spring Flower Shows in 1914.—We are extremely obliged to the many friends who have sent dates of exhibitions for inclusion in THE GARDENERS' MAGAZINE Almanac for 1914, but, so far, we have received very few dates of daffodil and other spring flower shows. If secretaries will send us such dates, on a postcard, addressed to the Editor, at 148, 149, Aldersgate Street, E.C., their kindness will be greatly appreciated.

Calceolaria Stewartiana. — From America we learn of the début of a new hybrid calceolaria, raised in the Arnold Arboretum, and named in honour of Mr. W. J. Stewart. The parentage is given as C. rugosa and C. hybrida; a large specimen recently exhibited before the Florists' Club at Philadelphia, created quite a sensation. The flowers are clear yellow, and about an inch across. C. Stewartiana is propagated freely from cuttings, and the general opinion is that it will make a fine greenhouse plant. It remains to be seen how this new-comer compares with the series of hybrids raised lately in England.

Dahlia Jaurezi.—Mr. C. Turner, Kew View Gardens, Highgate, writes: "The reference in your issue of October 18 to this fine old dahlia served to remind me of its use at Eaton Gardens, Chester, some years ago. It was there planted, in conjunction with Acer negundo variegata, in some enclosures in the pleasure grounds which were in front of the house. The combination used to appeal to me as very effective, especially when viewed from the higher ground of the terrace. I have never seen these two subjects associated at any other time or place, but I suggest the arrangement is worthy of copying, in spacious gardens at any rate. The bright scarlet of Dahlia Jaurezi was quite telling, seen against the light variegation of the acer."

Independent Trials of Roses in America.—From time to time we have urged the desirability of holding an independent trial of roses in this country, preferably under the auspices of the National Rose Society, but we confess our efforts have not received much encouragement, and the chief argument against such trials seem to be the fact that certain varieties do well in one district and not in another, therefore a trial in any given locality would not be of real value. We are glad to find, however, that the American Rose Society is taking up this idea of an independent trial or test with great enthusiasm. It is proposed to establish a rose garden of two acres at Urlington Heights, with Mr. Mulford, of the Department of Agriculture in charge. Three members have been appointed to form a permanent rose garden committee, and this committee is preparing plans for the garden, and taking into consideration the arrangement of famous rose gardens in Europe as well as those already established in America. Professor L. H. Bailey is joining with the society in the consideration of a test garden for roses at Ithaca, in connection with the Cornell University. Minneapolis and New Jersey have similar projects in view, and the authorities are being urged to combine so that a general

scheme of useful work may be conducted. If our own National Rose Society does not give this matter its serious and earnest consideration, it will soon be following where it ought to lead.

A Newly-produced Flora.—Mr. N. Colgan has given in the "Irish Naturalist" some interesting particulars of the renascence flora of some areas on Killiney Hill, Co. Down. These areas were covered with old gorse, which was burnt out in July, 1911, and within three months of the fire there were growing on the burnt areas thirteen species of flowering plants, some survivals from old root-stocks, some immigrants from adjacent unburnt areas, and some probably the product of seeds that had retained their vitality throughout the fire. Observations made eighteen months after the fire showed that a renascence flora of sixty-four species, including nine cryptogams, had taken possession of the areas burnt clear of all vegetation. Of these species, forty-five had entered from adjacent unburnt areas, thirteen were survivals, and the remaining six are classed as of doubtful origin. The cryptogams covered a much larger area than the flowering plants, the most abundant species, dominating above all other plants in the burnt ground flora, were the mosses Funaria hygrometrica and Barbula fallax.

Tree Planting in Norway.—To assist in the work of re-afforestation and the planting of untillable areas in western Norway the Bergen Tree-Planting Society was founded thirteen years ago. At first it made small progress, but of late it has received Government aid, and the assistance of wealthy and patriotic contributors, consequently the prospects of the society are better, and there is a hope that it may yet carry out the enormous task it set itself. Already over 36½ millions of forest trees have been raised, and of these over 26 millions have been planted on 10,000 acres of land. A great encouragement for the society's work is to be found in the fact that since its inception no fewer than 144 other tree-planting societies have been established, chiefly in the Bergenhus counties.

Preservation of British Flora.—In a paper read before the Botanical Section of the British Association on "The Preservation of the British Flora," Mr. A. R. Horwood said so urgent had this matter become that it was important the Botanical Section of this Association should discuss the question with a view to the possibility of taking some preventive steps. It was established now that severe drought recurred in cycles. During 1911 several instances of the extermination of plants were communicated to him, and others were personally noted. If they were to be expected every few years some steps should be taken to prevent their effect being disastrous. Montane and ericetal species were particularly susceptible. Bog-pools were also liable to be completely dried up. Drainage was a great factor in disturbing the natural vegetation of the country. A single instance, the Fens, sufficed to show how great such an effect could be. Fortunately some parts of it remained to show the special type of vegetation, but these were disappearing. Peat-cutting in Ireland had an effect of much the same nature, and thereby bogs were turned into tussocky pasture of Juncetum communis type. Forestry had been much neglected in the past, and, apart from the effect on the moisture of a district, the neglect to plant trees, where they were cut, except where afforestation associations existed, destroyed the natural ground flora. Golf links were extremely detrimental to those plants that only grow on sand-dunes and contiguous tracts along the coast, limited in area, and also inland heaths, now few in number. He suggested that in every case where such causes (only a few had been mentioned) were at work an endeavour should be made to obtain in the case of an association of plants a reservation, and in that of a single station for a rare plant some adequate means of protection.

Arsenical Poisoning from Sprayed Apples. — In a recent issue of the Norwegian "Morgenbladet" Dr. Sopp, who is well known in Norway as a food bacteriologist, warns the public against the possibility of arsenical poisoning from eating apples imported from Canada and the United States. Dr. Sopp states that owing to indisposition after eating apples he was induced to examine a number of apples from these countries, and found on them, in the hollow near the stalk, a visible layer of a green powder. A microscopic examination showed that the green powder contained both copper and arsenic—more than sufficient to explain the symptoms if the apple was carelessly peeled. The presence of the poison is attributed to the practice of American and Canadian growers spraying the trees, in some cases after the fruit has set, the amount of rain between this time and gathering the fruit not being sufficient to wash away the spraying material from the eye and around the stalk. Careless spraying should, of course, be avoided, but, with ordinary care, there is practically no danger whatever of arsenical poisoning from apples.

NEW PLANTS AND FLOWERS.

PERPETUAL CARNATIONS.

Lady Fuller. — A new, large-flowered variety of fine form, with broad and fringed petals. Calyx and stem are both good, and the colour is a charming shade of salmon-pink. This belongs to the Mrs. Burnett group, but has larger flowers than that variety; 85 points. A.M., P.F.C.S., December 3. Mr. Chas. Wall, Melrose Nursery, South Down, Bath.

Queen Alexandra.—This rich salmon-pink sport from the famous Scarlet Glow gives the warmest tone of salmon-pink yet seen in carnations. A strong grower, bearing finely-formed flowers, this newcomer should be certain of considerable popularity. It gained 77 points out of a possible 100. A.M., P.F.C.S., December 3. Messrs. G. Clarke and Co., Leighton Buzzard.

Cinderella.—A bold and striking variety, already described in these columns. It has broad petals of a purplish-heliotrope shade, freely flaked with scarlet; 75 points. A.M., P.F.C.S., December 3. Messrs. George Fairbairn and Sons, Carlisle.

Champion—A superb American variety, bearing large, full flowers, composed of broad and fringed petals. The colour is a fine rich shade of scarlet, and probably this is the greatest advance yet seen in the scarlet section. So far as we could discover it possesses no fragrance. A.M., P.F.C.S., December 3.

Gorgeous.—A very fine new American variety, and considered by many to be the finest variety yet raised by Mr. Peter Fisher, of Lawson fame. The large, full blooms are

CARNATION LADY FULLER.

A fine, new salmon-pink perpetual variety, honoured by the Perpetual Flowering Carnation Society on December 3, when exhibited by Mr. C. Wall, Melrose Nursery, South Down, Bath.

shapely, and composed of broad, fringed petals. The colour is rich cerise, with salmon-scarlet, flushing at the base of the petals, stem and calyx good; slightly fragrant. A.M., P.F.C.S., December 3.

Enchantress Supreme.—A lovely carnation, and with better calyx than Enchantress, from which it is a salmon-pink sport. It makes up a grand flower, large and full, and borne on long, stout stems. A.M., P.F.C.S., December 3.

These last three varieties are of American origin, and, according to P.F.C.S. rules, the awards are not credited to any particular grower.

CATTLEYA MRS. TEMPLE, VAR. DREADNOUGHT.

An exceptionally large-flowered cattleya, and with unusually substantial sepals and petals. These latter are rich rose-purple, and the large, broad lip has a deep crimson-purple apex, speckled with white, and having a handsome gold veined throat and yellow side lobes. A.M., R.H.S., December 2. Mr. C. J. Phillips, The Glebe, Sevenoaks.

LÆLIO-CATTLEYA AUTO-DOIN.

The interpretation of this quaint name may be found in the fact that the plant is a hybrid derived from Lælia autumnalis and Cattleya Octave Doin. The hybrid is a good one, and has the extended inflorescence and habit of growth of L. autumnalis, modified by the influence of C. Octave Doin, which has very greatly enlarged the blooms. These latter have broad segments of a soft mauve-purple shade, and a lip exquisitely coloured with mauve-purple, gold, and white. A.M., R.H.S., December 2. Messrs. J. and A. McBean, Cooksbridge.

ODONTIODA LATONA GOODSON'S VARIETY.

The fascination exercised by the odontiodas grows steadily, and Goodson's variety of O. Latona, with its long spike and fair-sized, rounded flowers of rich orange-red colouring comes very near the ideal of a scarlet odontoglossum. The spike carried eleven expanded blooms, and there were five other flowers to open. Such robustness, beauty, and brilliance of colouring, will go far to increase the popularity of odontiodas. A.M., R.H.S., December 2. H. S. Goodson, Esq. (Gardener, Mr. Day), West Hill, Putney.

ODONTOGLOSSUM SATURNE VIOLACEUM.

Of modest growth, this interesting hybrid between O. nebulosum and O. crispo-Harryanum is attractive by reason of the bright red and red-brown colouring in the lip, and the spottings of similar colour on the white, rose-tinted sepals and petals. The rich orange-brown of the throat and the soft yellow column add to the effectiveness of the flower. Though not so rounded in form, this hybrid shows a distinct resemblance to O. nebulosum. A.M., R.H.S., December 2. Mons. Henri Graire, Amiens, France.

CYPRIPEDIUM GOLIATH.

A very large cypripedium with the general character of C. insigne Harefield Hall, which was one of the parents, C. Amy Moore being the other. The broad dorsal sepal has a white apex and purple-brown spots over the green base and centre. The petals and lip are green, shaded with cream and brown. A.M., R.H.S., December 2. W. R. Lee, Esq., Plumpton Hall, Heywood, Lancs.

CYPRIPEDIUM STRELSA.

A neat hybrid with very rounded flowers. The dorsal sepal is wide and short, white and green, with purple spots. The lip and petals are green and brown. The widening of the ventral sepal, the roundness of the upper sepal, and the comparatively small size of the lip give to the flowers of this cypripedium a very distinct and compact appearance. A.M., R.H.S., December 2. W. R. Lee, Esq., Heywood, Lancs.

BEGONIA ROSALIND.

A fine addition to the winter-flowering section, and derived from B. Socotrana and a white, tuberous-rooted variety. It is of sturdy habit, and has very large single flowers, carried on stout stems. The colour is rich rose with a distinct flush of carmine. A.M., R.H.S., December 2. Messrs. James Veitch and Sons, Chelsea.

CHRYSANTHEMUM MAUD JEFFRIES.

This is by no means a new variety, but it is a very useful late one of Japanese form. It can be grown well in small pots, and its pure white blooms at this season of the year are very welcome. We have illustrated the variety, as grown by Mr. Cradduck, in our pages, and also given Mr. Cradduck's system of cultivation. A.M., R.H.S., December 2. Right Hon. Colonel Mark Lockwood, C.V.O., M.P. (gardener, Mr. Cradduck), Bishops Hall, Romford.

VIOLET KAISER WILHELM.

This is a variety of outstanding merit because, while its flowers are of the largest size, the petals are broad and rounded, and the stems are long; these good qualities are coupled with the richest violet fragrance. The colour is rich violet-purple, with a small white eye. We have previously drawn attention to this fine novelty. A.M., R.H.S., December 2. Mr. T. Johnson, Motcombe Gardens, Shaftesbury.

PROTECTION FOR HORTICULTURAL NOVELTIES

The leader in the issue of THE GARDENERS' MAGAZINE for December 6 provides much food for thought, especially among those who are called, for want of a better term, "raisers." I think it must be admitted that at the present time, more so than in the past, raisers do not receive their fair share of the profits arising from any novelty they introduce to the public. This is certainly not as it should be, because a man who has used his brains, time, and money to some purpose, should surely reap the lion's share of the reward. Take, for instance, the raisers of new fruits. They must grow their novelties at least ten to twelve years before they secure a thorough test and can work up a stock; this means a very heavy outlay. With what result? Why, the moment the variety is introduced, down come the rest of the fruit tree growers and buy up all they can get, and it is immaterial whether the variety is offered in the trade or not. Neither does the price prove detrimental; the growers must have the novelty, and every bud is worked, with the result that plenty of trees are on the market long before the raiser has reaped his just reward. It is business, of course; business, nothing more or less.

The rose-raisers are in much the same position, for there are always thousands of stocks ready to receive the buds of a new variety when it is placed in commerce. Chrysanthemums, dahlias, and other flowers are treated in like fashion.

So far as I can see, the only way out of the difficulty is for the raiser to make every firm who buys his novelties sign an agreement that they will not cut prices for at least three years, and the raiser must retain the right to fix the price. I remember this sort of thing being done, in a modified form, in the case of a new strawberry, and, so far as I know, it answered very well. I also know of an instance where a chrysanthemum was sold under similar conditions, and I should imagine it proved satisfactory all round.

Other methods of protection have been tried, such as the registration of the name, but this evidently has not been a success; in fact, it would be very difficult to register a name and keep the stock as well. There are registered names of chrysanthemums, and the varieties have not been offered for sale under that name, but they are out all the same; certainly not under their proper names. Probably the general public would see little of interest in a variety advertised as No. 1 Yellow; but the trade recognises at once that it is a registered variety and cannot be sold as such, but when offered under a number it is safe to purchase what they know to be a really good thing. The stock has not been purloined in any way, for the flowers have been purchased in the open market, and stock raised from the stems; a perfectly legitimate proceeding.

If our continental friends can devise a scheme whereby the raiser has his due reward I have no doubt the traders in this country will be prepared to fall into line; but hitherto all general attempts at protection have been unsuccessful. But surely the difficulty is not unsurmountable, at least, I trust not. R.

I was very pleased to see the article in THE GARDENERS' MAGAZINE under the above heading. It was only on December 1st that I sent out a circular to all those members of the Perpetual-Flowering Carnation Society who trade in this particular flower, suggesting to them that we should co-operate with and generally support any grower who was fortunate enough to bring out a really good novelty. To a grower or raiser of any variety it means a very great expense to obtain that novelty. Having obtained it, he offers it to the whole world at a certain price. He not only offers it to the private grower, but he gives the trade an opportunity of purchasing, and making a small profit on it as well. What do the traders do the following year? In many cases, the variety is offered by them to the public at a much lower figure than the original raiser of the novelty is prepared to accept, and, under these circumstances, the originator has but a short run with the flower as a novelty. It is made too common.

Let us appreciate the trouble and expense he has been put to, and reward him by giving him all the support we possibly can. Let the novelty remain as such for at least two seasons. This will enable the raiser to secure some reward for the trouble he has taken, and encourage him to continue his work of improvement and the raising of further novelties. On the present lines the encouragement is small. All who trade in the carnation should co-operate in this matter, as it is only by co-operation that proper support can be given to the raiser of any novelty, no matter whether it be a carnation or any other flower. We in England seem to look upon our neighbour with suspicion. Let us cast off this suspicion, and look upon our neighbour as a friend, give him our hearty support, co-operate with him, and so secure for each other the best to be had in this world.

Fairoak, Eastleigh. E. J. WOOTTEN.

ESCALLONIA ORGANENSIS.

This distinct and uncommon species of escallonia has been several times of late shown at the Horticultural Hall, in the shape of cut sprays. This fact goes to prove that, like many other members of the genus, its flowering season extends over a lengthened period. It is a free-growing evergreen shrub, with firm textured leaves, about three inches in length, and half an inch wide, with much serrated edges. When in a young state the leaves are suffused with reddish-brown, while the same colour extends to the leaf stalks.

The flowers, which are borne in terminal corymbs, are of a deep rose colour, and very attractive. According to the "Hortus Veitchi" this species was first detected by the collector Gardner, but introduced by William Lobb, who sent seeds to the Messrs. Veitch, and the plants raised therefrom flowered for the first time during the summer of 1846. Like most members of the genus, this species can be propagated by cuttings taken in July or August, and placed in a close and shaded frame till rooted.

W. T.

PERGOLAS IN ENGLISH GARDENS.

The pergola is an exotic, and, that being so, its free use is to some extent restricted in English gardens. Its prevalent use as a means for supporting and giving effect to climbing plants, of which rambling roses, wistarias, polygonums, clematis, and vines are familiar instances, is so fully recognised that it is unnecessary to enlarge upon this aspect of the question at present. There is, however, a tendency, when the pergola is introduced indiscriminately, to destroy a certain amount of the repose that one instinctively feels should be a characteristic of a private garden, and this must inevitably follow when a pergola is built merely for the spectacular effect it will produce. When its relation to other features, more in sympathy with a typical English landscape, is ignored, it must frequently happen that, instead of proving a necessary part of a connected scheme, an ill-considered pergola is a source of offence.

Italy is usually regarded as the home of the pergola, and there its practical use is to afford a screen from the sun; we may rightly regard it as a lateral development of that art which has bequeathed us those faultless terraced gardens of the formal school, and as such its stone columns and paved covered-way would readily harmonise with the garden scheme. Its wealth of overhead growth would form admirable shade from the violence of the sun's rays, the stone pathway would impart a coolness not to be despised, while the beauty of the pergola, as seen from the mansion, would be considerable when we recollect that in the majority of instances it would be on a lower level.

It is not always possible to apply a rule literally, and this holds good with pergolas in our country. There are occasions when a simple structure of larch poles will give an element of beauty that we cannot fail to admire; the effect will be greatly heightened if we can bring the mast-like stems of conifers into the garden picture, in sympathetic harmony with the scheme; such an arrangement would give the most pleasing results in less formal parts of the garden. Some country houses are built on the half-timbered principle, and were a pergola thought desirable in proximity to such a house, then an arrangement of squared-oak vertical beams, with a lighter superstructure of the same material, would, in all probability, give good results.

A pergola arrangement of considerable beauty, herewith illustrated, forms an integral part of an extensive scheme of formal gardening, arranged on terraces immediately below the level of the mansion. The pergolas, of which there are two, are arranged as the flanking members of what is, roughly, a square; they occur on the intermediate level, so that from the highest terrace the spectator views the overhead portion; it is, therefore, possible to appreciate their beauty from different points of vantage. The rounded columns have square bases, with a square cap and moulded plinth, and rest upon a low wall; the ties between the columns are squared beams of dark oak, while the cross pieces are of the same material, but of a lighter build. The substantial nature of the structure gives an impression of strength and great spaciousness, features that are desirable where a broad effect is necessary.

As to the details of planting, the climbers carried up the columns and overhead are drawn from those genera previously mentioned, in addition to which the common ampelopsis is largely made use of, both on account of its luxuriant leafage in summer and the brilliant tints at the fall of the leaf in autumn. In the narrow borders that run parallel with the pergolas, on either side, an extensive scheme is carried out by the aid of Lilium longiflorum; the illustration gives some idea of the effect of what is practically an unbroken chain of white, although it conveys no idea of the subtle aroma that pervades this part of the garden during the period when the lilies are in flower.

PERGOLA AT COOMBE COURT, KINGSTON, SURREY.

The entrance to the pergola consists of broad steps of stone, leading upwards by easy "risers"; the ends of the steps are built into hollow brickwork, which is arranged on both sides in the form of ramps; each ramp makes a receptacle that is filled with soil, and in which plants of the common Lavender Cotton (Santolina) have been planted, and their light, fleecy, grey shoots form a most pleasing feature, while the plant emits a delicate fragrance whenever it is bruised or rubbed against. Although most special studies have chiefly a local application, it is generally possible to derive some suggestion, principle, or little detail from them, capable of elaboration under different conditions, and in various parts of the country.

THOS. SMITH.
Coombe Court Gardens, Kingston.

SELECT GRAPES FOR PRESENT PLANTING.

The renovation of old vine borders, making new borders, and planting new vines, are matters of present importance, therefore a note on the most desirable grapes to grow may be useful to intending planters. Although new varieties of many fruits, as well as flowers, are always appearing, I do not remember the addition of one new grape during the last decade, and even those introduced a few years earlier are not indispensable.

The newest variety, Prince of Wales, a sport from Mrs. Pince, is not popular, and this is probably due to ignorance of its special requirements. It is seldom we see satisfactory specimens and so one is forced to the conclusion that, good grape though it is when seen at its best, it does not find favour with growers. Lady Hastings, a sport from Madresfield Court, does not commend itself generally, and Melton Constable, although easier to colour than Gros Colmar, makes little progress in popular favour.

Black Hamburgh.

Black Hamburgh is, without doubt, the most popular of all grapes. It may be ripened with ease in April, and crops may carry the supply well into October. In any form it is suitable. It succeeds as well in a small vinery, or even a pit, as in a large house. Under warm treatment it is a success, and it thrives without artificial heat. As a grape for the amateur in his greenhouse or conservatory, it is as much at home as in the market-growing establishment. One vine will fill a house, large or small, with equal success. It has a strong constitution, is of free growth, and the wood produced is never excessive in size, and always ripens well under reasonable treatment.

Unfortunately many persons crop Black Hamburgh vines too freely, and this results in failure, or partial failure, the grapes refuse to colour perfectly under such conditions, and occasionally shanking takes place, which means a loss of crop as well as disfigurement. The bunches are of medium size, averaging from 1lb. to 2lb. each in a general way, with broad shoulders. The berries set freely under any method of culture, are large, usually round, though sometimes they are roundish-ovate, generally quite smooth, though occasionally they have a distinctly hammered appearance, which is regarded as a sign of high culture. The skin is deep bluish-black, covered with a fine bloom. We learn that the variety was imported from Hamburgh in the early part of the last century by a merchant, who established a vineyard in the neighbourhood of London. It has no fewer than twelve synonyms.

Madresfield Court.

Madresfield Court ranks next in popularity among black grapes. The strongly-marked muscat flavour is perhaps more appreciated than that of the Black Hamburgh, but as a vine it is not so useful, being less amenable to various forms of culture, and the grapes do not ripen so early. It is a valuable grape, however, now that its culture is better understood. At one time growers complained of the manner in which the berries split just as colouring commenced, and not a few gave up its cultivation. To remedy this weakness one must allow a more free growth of the laterals when colouring commences, and at the same time maintain a more buoyant atmosphere.

No grape succeeds better on the extension principle of increasing the number of rods yearly. Under this method one vine will quickly fill a moderately-sized house, and bear huge crops of excellent grapes, quite equal to those on vines restricted to one rod only.

In the corner of a cool peach-house this grape succeeds admirably, as its constitution is of the best. The growth is moderately strong, the current season's shoots invariably ripen well, and so the bunches are freely produced. The berries swell and ripen quite easily, and seldom exhibit signs of shanking; they are also extra large, ovate, borne on stout footstalks, and they set freely. The flesh is thick, greenish, very tender, sweet and rich. The late Mr. Meredith, at Garston Vineyard, near Liverpool, was the first to demonstrate how well this grape would grow treated on the extension system, and this style of training is followed up by Mr. Shingler, at Melton Constable, in Norfolk.

Alicante.

Alicante is the most easily grown grape, producing a heavier crop per rod than any other variety. The bunches average from 2lb. to 6lb. in weight, and are broadly shouldered, but, unfortunately, the quality of the grape is but moderate. The growth is strong, vigorous, and free. The berries set well, almost too freely, and render thinning a difficult matter. As an amateur's grape for a cool house it is valuable, being exceptionally free from disease, and not subject to attacks of red spider. As a grape to use about Christmas-time it is useful, keeping well when properly ripened, provided the berries are left wide apart when thinned, thus enabling air to pass freely among them and quickly disperse condensed moisture.

Lady Downe's is one of the most valuable of late grapes, as the bunches will hang on the vine until January, or even later, and then they may be kept until June in a grape-room. The bunches are long and narrow, with large, round berries, that generally colour easily and carry a dense bloom. The skin is thick, tough, and leathery. In flavour this variety is brisk and sparkling, sweet and rich. The vines carry a heavy crop of fruit, which seldom shows any tendency to shanking, but the berries are liable to scald if there is any lack of attention in regulating the ventilation of the vinery.

Appley Towers deserves more attention than it receives as a late grape, being much superior in flavour to Alicante, Gros Colmar, Gros Maroc, Alnwick Seedling, or even Lady Downes. In appearance, too, it is superior, as the bunches are shapely, with large, even berries that colour quite easily and keep well into the New Year. As in the case of all other late grapes the berries should be well thinned.

Muscat of Alexandria.

Among white grapes we have not nearly so much choice; indeed, few require more than one variety, and none more than two. The finest of all white grapes is, of course, Muscat of Alexandria, but as it does not ripen well before July, where grapes are required all the year round an additional variety is needed, and Foster's Seedling or Buckland Sweetwater are the two best early sorts. Neither of these stand very high in point of quality, however. The former grows freely, and produces huge crops of fairly good fruit in May and June. The flavour is certainly third-rate. Buckland Sweetwater does not succeed so well as the former; its bunches are larger, but irregular in shape and fewer in number, but the quality is superior to that of Foster's Seedling.

Muscat of Alexandria, when well cultivated, is perhaps the most esteemed of all grapes. The bunches should range from twelve to twenty inches in length, and from 2lb. to 6lb. in weight. The berries are large (according to treatment), but the variety is certainly a somewhat shy setter, and perhaps it is the most difficult of all grapes to grow really well. There is no doubt soil has much to do with the ease or difficulty experienced. The foliage, too, is much more robust in some localities than in others. It is rarely a success in a mixed collection, as a higher temperature is required for setting and to ripen the fruit than is necessary with any other grape, therefore it should have a house to itself.

No grape has been the subject of so much discussion respecting improved varietal forms, but, in my opinion, there is only one of real worth, and that is the original Muscat of Alexandria, grown in this country probably for two centuries. I do not even attach any importance to the Bowood variety, and having grown this, as well as the Escholata variety, I have found no difference between them and the type.

E. MOLYNEUX, V.M.H.

Bishops Waltham.

THE BEST-FLAVOURED NECTARINES.

Having been asked which are the best-flavoured nectarines for early, middle, and late season use, it has occurred to me that the reply might well be given through the columns of THE GARDENERS' MAGAZINE.

For early use, i.e., for forcing, preferably in pots, I recommend Early Rivers before Cardinal, for unless the last-named be well understood and carefully managed it is inclined to be a little "woolly" when fully ripe; in fact, it wants using immediately it is ripe, as it does not keep well. As a second, to succeed Early Rivers, I advise Lord Napier; this is a well-known and reliable variety. My third choice is Dryden, a very fine nectarine of high-class flavour, and one of the handsomest of all. Rivers' Orange would be a good substitute for Dryden.

The fourth, in my opinion, is Pine Apple, one that is well known, and one that keeps so well in good condition when it is ripe, and, moreover, one of the very finest in point of flavour. Humboldt I place fifth on the list. It is a superb nectarine, and if I had to choose between the two I should give it preference over the preceding, but it is later, under the same conditions. My last in a list of six is Victoria, which is one of the hardiest and, in my opinion, one of the best of the set.

This list is drawn up on the understanding that the nectarines will be cultivated under glass, but it would equally apply to wall culture outside, under the best of conditions as to aspect, etc.

JAS. HUDSON, V.M.H.

Gunnersbury House Gardens.

MELTON CONSTABLE GRAPE.

Unfortunately the handsome grape named Melton Constable has a rather bad reputation, because it appears that some canes of Gros Colmar were mistakenly distributed for it in the early days of its history. As growers did not want Gros Colmar under another name Melton Constable suffered accordingly. My father considers Melton Constable quite a fortnight earlier in commencing growth than Gros Colmar, and that under similar conditions it colours better, is of superior quality, and has a thinner skin. It certainly is a very handsome grape. I send this note because your representative drew my attention to both the varieties mentioned when at Norwich Show. A. R. ALLAN.

CARNATION MRS. C. W. WARD.

When a perpetual-flowering carnation obtains an Award of Merit from the Royal Horticultural Society and a First Class Certificate from the Perpetual-Flowering Carnation Society, it has passed the tests of two impartial and keenly discriminating tribunes, each familiar with new and old varieties under cultivation and at exhibitions. The variety herewith illustrated has secured these hall-marks of excellence, and, therefore, needs little further recommendation. Already this beautiful, free-flowering variety has become a favourite with those growers who cater for the cut flower trade, and this fact alone is of great importance, as a variety which can stand the commercial test is certainly a good one for the private grower, because habit, excellence of stem and calyx, size, substance, form of flower, and freedom must all combine in a first-rate market variety. The colour of Mrs. C. W. Ward is deep, rosy-cerise pink. The variety is of American origin. At the exhibition at Westminster on December 3 it was staged by many growers, but Messrs. Allwood Brothers, Wivelsfield, Haywards Heath, had an especially fine vase of blooms in their large competitive stand. The flowers attracted general attention by reason of their size, freshness, and beauty, and lady visitors greatly admired them. B.

CARNATION MRS. C. W. WARD.

A beautiful perpetual-flowering variety, with rosy-cerise, slightly fragrant flowers.

THE HORSE CHESTNUTS.

(Continued from Page 920.)

Æ. chinensis.

A Horse Chestnut peculiar to China has long been known, through the collection of dried specimens, to exist, and several attempts have been made by collectors to secure it. Mr. E. H. Wilson was successful in obtaining a Horse Chestnut during his travels in China, and this was thought to be the long-sought-for plant. Comparison with the original description of A. chinensis (Hurge), however, proves Mr. Wilson's plant to be another new species, which has been named A. Wilsoni.

It has been left to Mr. W. Purdom, one of the latest collectors in China, to introduce living specimens of the true Æ. chinensis, which he did last year when collecting, on behalf of Messrs. James Veitch and Sons and the Arnold Arboretum. In the hills west of Peking, where Mr. Purdom discovered it, the tree attains a height of 50ft. or more. It is, of course, much too early yet to attempt to say how the tree will behave in this country. Being an inhabitant of Northern China, we may reasonably expect the Chinese Horse Chestnut to be at least as hardy, probably hardier, than Æsculus indica, the Himalayan species. It differs from the latter in having narrower, more slender panicles, with rather smaller flowers and petals. There are also other botanical differences.

Æ. flava.

This is the tallest of the North American chestnuts or buck-eyes, attaining in that country a height approaching 100ft. A few specimens in this country range from 50 to 70ft. First introduced in 1764, it is popularly known as the Sweet Buckeye in the United States, where also the botanical name of Æ. octandra is preferred to the one at the head of this paragraph. The leaves consist of five or seven leaflets, light green in colour, up to seven inches long, and pubescent beneath. As the name suggests, the flowers are yellow, borne in panicles 5in. or 6in. long; stamens short, enclosed within the petals. The trees flower towards the end of May. The fruit is smooth.

Æ. glabra.

Also a native of America, this species inhabits the South-eastern and Central United States. It is known as the Ohio Buck-eye. The introduction of this species and Æ. turbinata suggested that the generic name of Pavia should be dropped in favour of Æsculus, as the flowers have only four petals, but the fruits are spiny, like the Horse Chestnuts, the reverse holding good with Æ. turbinata. In growth the tree resembles Æ. flava; the distinguishing characters are the stamens, which protrude some distance beyond the petals, and the spiny fruits, while the petals—at any rate, in some of the forms—are not so bright yellow as in the Sweet Buckeye.

THE INDIAN HORSE CHESTNUT.
(Æsculus indica.)

Æ. indica.

The Indian Horse Chestnut is a native of Kumaon and other parts of Northern India, growing at an elevation of from 8,000ft. to 10,000ft., where it is said to be quite as large and attractive as the Common Horse Chestnut is with us. The largest tree in this country is at Mildenhall, Suffolk. This was raised from seed sent home by Colonel Bunbury to his brother in 1851. It flowered for the first time in 1858, and is now about 70ft. high. The leaves consist of seven, rarely nine, leaflets, up to 1ft. long, rich dark-green in colour, with red stalks, giving the tree an almost tropical appearance. The leaves retain this luxuriant character until late in the season, hanging on the trees after most other chestnuts are bare. A most important point of value with this tree is that it flowers in June and July, when a great many of our most showy flowering trees are over or past their best. The panicles of flowers are as long as, or even longer than, those of the Common Horse Chestnut, sometimes exceeding a foot in length. The flowers are white, blotched at the base of the petals with yellow and red. The long cluster of upward curving stamens is prominent. Trees flower annually at Kew, and in favourable seasons mature the large brown, spineless fruits, which germinate readily if sown as soon as ripe. Previous reference to trees growing in this country show the tree to be fairly hardy, though, if good results are to be looked for in the Midlands and North, shelter is very desirable.

Æ. parviflora.

The bushy character of this Æsculus caused it to be named the Shrubby Buck-eye. In some catalogues the name of Pavia macrostachya is still used. A native of the South-eastern United States, it has been in cultivation in this country for nearly 150 years. Why such a beautiful hardy shrub, which flowers freely during late July and August, is not more generally grown is difficult to understand. Growing from 8 to 12ft. high, the bush spreads over the surrounding ground, and in time forms a large clump of slender branches. The leaves are dark green, and consist of five or seven leaflets. The white flowers are borne in narrow panicles 9in. to 12in. long, with prominent thread-like stamens. The fruits are smooth, and, during a favourable autumn, mature in this country. In addition to seeds, the Shrubby Buck-eye may be propagated by layering the branches, or by division of the clumps. Useful alike as a flowering shrub for large and small gardens, Æsculus parviflora may be planted as a lawn specimen or in the shrubbery border.

Æ. Pavia.

The Scarlet or Red Buck-eye hails from the Southern United States, and is usually a shrub, sometimes a small tree. Cultivated specimens in this country are usually the latter, being grafted on Æ. Hipposcastanum or Æ. flava. The numerous twiggy branches are inclined to be drooping, so that when grafted as a standard the trees form attractive lawn specimens. The leaflets are in fives, and are the last of the genus to fall in autumn. A June-flowering species, the red flowers are borne in panicles up to 6ins. long. The fruits are smooth. Numerous hybrids between the Red Buck-eye and Æ. flava are in cultivation, most of them raised in America, but we need not discuss these at present.

Æ. plantierensis.

With the exception of Æ. carnea this is quite the best of the hybrid Horse Chestnuts. It is said to have originated in the nursery of Messrs. Simon Louis, at Plantières, near Metz, as a chance hybrid between the Common Horse Chestnut and Æ. carnea. Characters of both parents can be traced in the hybrid, for while the trees are as vigorous as the common species, which is the seed-bearing parent, the flowers are an attractive shade of pink, showing the influence of the pollen-bearing parent. Though the tree flowers very freely at Kew no fruits are produced. Grafted on the Common Horse Chestnut, the trees are quite as free and fast in growth as that species. Too much can hardly be written in praise of this beautiful hybrid.

A. OSBORN.

(To be continued.)

ARTISTIC ROCK GARDENS.

Perhaps two-thirds of rock gardens, counting both the finest and the poorest, are spoiled by the similarity of size, if not of shape, found in the rocks employed. In Nature's rocky scenes the boulders are there as well as the cast pebbles, and all intermediate sizes are represented. To set up blocks, about a foot square, and make an artistic rockery is impossible, for the simple reason that Nature's achievements are not cut by machinery, like cube sugar! So the smallest rock garden, being consciously, or unconsciously, modelled on natural lines, should show stones of all suitable shapes and sizes. An alpine rockery is easiest to plant, as it can include a vast number of perennial species. However, there might be several other kinds—a South American sandy pass, between high rock banks, ablaze with poppies, eschscholtzias, etc., a South African craggy gorge, brilliant with ixias, stately with arums and gladioli; or a Chinese ascent, or rocky plain, radiant with its pæonies. A woodland rock garden would be fairest, because most in sympathy, near an English stretch of park; and primroses and bluebells are never so welcome, anemones so bewitching, or foxgloves as graceful as when occupying levels and slopes of varying heights, so that some flowers nod above the head of the visitor while others spring about his feet. Young silver birches and firs, catkin-bearing sallows, and a few young dark hollies, would be in place there among the carpeting turf, moss, and flowers, and the honeysuckles and single roses.

A rock garden to include water may be carried out on a large or a small scale. In the latter case it may consist only of one or two pools, with clay-beaten, not stone-rimmed sides, and of irregular shape. In the former case a wonderland of charm should result, glade leading into glade, flanked by silent water, bowered over by roses, with reeds, swamp lilies, and gorgeous phloxes in the moist places, shaded here and there by thickets of bamboos and polygonums; and, perchance, a quick stream with tumbling waterfall may be arranged.

Many years ago a writer in Chamber's "Edinburgh Journal" gave the following admirable hints on the making of a rock garden: "The rocky ravine, the mountain's brow, and the sea beach, are the most fertile sources of materials for a rockery; and it is necessary, in selecting them, to pay minute attention to the manner in which the various rocks are deposited in their several beds, and also to the mosses, heaths, and ferns which are congenial to them; for, in proportion as the selection shall succeed in imitating Nature, will he please his own eye and gratify his friends. The size of the stones should always be varied, but proportioned, upon the whole, to the intended size of the rockwork. A number of detached erections never look well; they are stiff and artificial. Rocks of the same kind and colour should be placed together; if intermixed they seldom wear a natural appearance. A dark cave, penetrating into the thickest part of the erection, is not very difficult to construct, and when encircled by ivy and inhabited by a pair of horned owls, which may be easily procured, it will form a most interesting object. Rock plants of every description should be profusely stuck around, and in one short twelvemonth the scene will exhibit an impress of antiquity far beyond anticipation. The whole should be enclosed by trees of large foliage, that the visitor to the scene may come upon it unexpectedly."

Just as, within a well-arranged museum, the stuffed birds, beasts, and reptiles are surrounded by branches, foliage, and blossoms, earth and stones, suited to their nature and habits, so the flowers should harmonise with the rocks, and the rocks with the trees. A convenient slab may be left bare here and there, to serve as a seat.

There is no reason why a rockery bed, six feet by four, should be inartistic, but, alas! many a suburban garden contains "a very incongruous heap of stones, chiefly irregularly-formed flints, the scoriæ of forges, and large bits of coke from the gas works, covered with house leeks, sedums, and other plants." The safe rule for the gardener is to take Nature always for his teacher; she who plants in perfect glades and groups offers a dozen different styles of floriculture in one county, and "paints the meadows with delight." M. H.

ÆSCULUS PLANTIERENSIS.

A fine hybrid between Æ. Hippocastanum and Æ. carnea.

JAPANESE MAPLES.

Among the changes which taste in gardening has undergone during the past quarter of a century, that which has had the effect of obtaining for the more beautiful hardy trees a degree of popularity more commensurate with their merits than was formerly the case stands pre-eminent. Especially is it gratifying to observe, in visiting gardens and nurseries in various parts of the country, that the many beautiful deciduous trees which in the past were seldom seen beyond the boundaries of botanic gardens and long-established nurseries are being extensively planted, and that the recent introductions are also being taken full advantage of by planters.

As the result of this change in public taste gardens are being rapidly made more interesting and attractive, and the labour involved in their maintenance somewhat reduced, for if trees and shrubs are unable to take care of themselves, they do not require such close and constant attention as do many rock plants and some of the hardy perennials that are grown in the mixed border.

Not only is increased attention being given to trees remarkable for the beauty of their flowers or leaves, or for their elegant aspect, but greater care is taken in making selections to pay due attention to the consideration of the dimensions of the garden, so that it may be possible to have a considerable diversity in the arborescent vegetation without the semblance of overcrowding. Consequently, the practice which in bygone years so generally obtained of planting in gardens, of even quite moderate size, trees that properly belong to the park and woodland is fast dying out, and not a few giant elms and chestnuts, etc., are annually felled to provide space for kinds of more moderate development, and in other respects better adapted to the adornment of gardens wherein the space is limited.

Prominent among the deciduous trees with ornamental leafage are the Japanese maples, which include some of the most distinct and effective of trees of moderate stature. Hitherto owners of gardens, and indeed, plants generally, have been somewhat chary of planting them otherwise than in small numbers, owing to the mistaken impression that there is a considerable risk of their being seriously damaged, if not killed outright, in a severe winter. Constitutionally they may not be sufficiently robust to bear the rigours of a winter of exceptional severity over the whole of the United Kingdom, but they can do so over a large area, as exemplified by the many fine specimens that may be met with in a widely-extended tour.

JAPANESE MAPLES GROUPED ROUND THE LILY POND AND FOUNTAIN AT CASTLEWELLAN, CO. DOWN.

Acer palmatum.

When the forms of Acer palmatum, with which alone we are now concerned, are injured in a severe winter, as sometimes happens, the damage is due more to the immaturity of the new growth than to the low temperature. A considerable number of specimens have come under my notice during the past two decades that have been subjected to a temperature several degrees below zero without receiving any harm. A few also have been met with that have been damaged by a frost of less severity, although growing in gardens within a few miles of those in which the specimens that had passed through the winters unscathed had their home.

While it is of importance to regard these Japanese maples as much hardier than they are generally supposed to be, it will be advisable to recognise the fact that they may suffer from very severe frosts if the conditions under which they are grown are unfavourable to the completion and ripening of growth before the autumn is far advanced. If this fact obtains due recognition it will be readily understood that plants should have a sunny, sheltered position assigned them, and that soil be free from stagnant moisture.

It is essential the positions be efficiently drained, and in the majority of cases this will be so, but if this be not the case arrangements for carrying off the surplus moisture must be made before proceeding with planting operations. In all cases the soil should be broken up to a depth of two feet by ordinary or bastard trenching, and in the process such material must be added as may be considered desirable, this being, in a large measure, determined by the character of the soil. These maples require for their full development a comparatively light, open, and rich soil. Therefore, if the staple is heavy and close in tetxure, add light soil, leaf-mould, and coarse grit in liberal proportions. On the other hand, light soils will be improved by moderate additions of good loam,

decayed vegetable refuse, leaf-mould, and well-decayed manure from the farmyard. In either case the materials should be well incorporated with the staple throughout the depth to which it has been broken up. As in the case of other deciduous trees, the planting operations may be carried out at any time between the beginning of November and the end of February, provided the soil is in a suitable condition.

These maples may be grown as medium and dwarf standards, and as bushes, and if the conditions are favourable to full development, they will be highly attractive whatever may be the form in which they are grown.

Selection of Varieties.

The remarkably fine bush specimen herewith illustrated of Acer palmatum atropurpureum, in the unique collection at the gardens of Castlewellan, Co. Down, Ireland, the seat of the Earl of Annesley, will give an excellent idea of the effectiveness of large examples grown in this form. In these famous gardens this and other of the dark-leaved varieties are grown to form broad belts around the fountain and lily pool, and the great masses of glowing deep red foliage present a contrast at once effective and pleasing to the golden-hued and other fine specimen coniferous trees with which they are surrounded. The number of varieties in cultivation is considerable, and in making a selection from them the following should have the preference.

Acer palmatum, known for a considerable period in gardens under the name of A. polymorphum, was first introduced to this country from Japan by Dr. Siebold in 1820. According to Loudon there were plants in the gardens of the Royal Horticultural Society in 1844, and an illustration is given in his "Arboretum et Fruticetum" of a shoot, with leaves, taken from one of the plants. It was re-introduced, about half a century later, by Mr. John Gould Veitch, with a number of varieties, of which the greater proportion are now in general cultivation. A. palmatum assumes the proportion of a small tree, rising to a height of about twenty feet, in Japan, has bright green leaves, and is decidedly handsome.

A. p. atropurpureum is unquestionably one of the most effective of the dark-leaved varieties. The leaves are rather larger than those of the type, and, with the young shoots, are deep bronzy-crimson, the rich colouring being retained throughout the season of growth.

A. p. dissectum, an exceedingly beautiful dwarf variety, has growths which are long and slender, with a tendency to droop, and the leaves are deeply cut, as also are the lobes. The foliage is of a bright green, and so graceful as to render the variety of much value for associating with cut flowers.

A. p. aureum is a handsome form, differing from the type chiefly in the colour of the leaves, which are of a yellow hue, changing to deep yellow and orange-red in autumn, when it is exceedingly beautiful.

A. p. linearilobum is a distinct variety of great beauty. The leaves are rather above the size of those of the type, and are deeply cut, the lobes being long, narrow, and slightly toothed. In the earlier stages the leaves are, with the shoots, suffused with red, but in process of development they change to bright green, with reddish margins, the leaf stalks retaining their red hue.

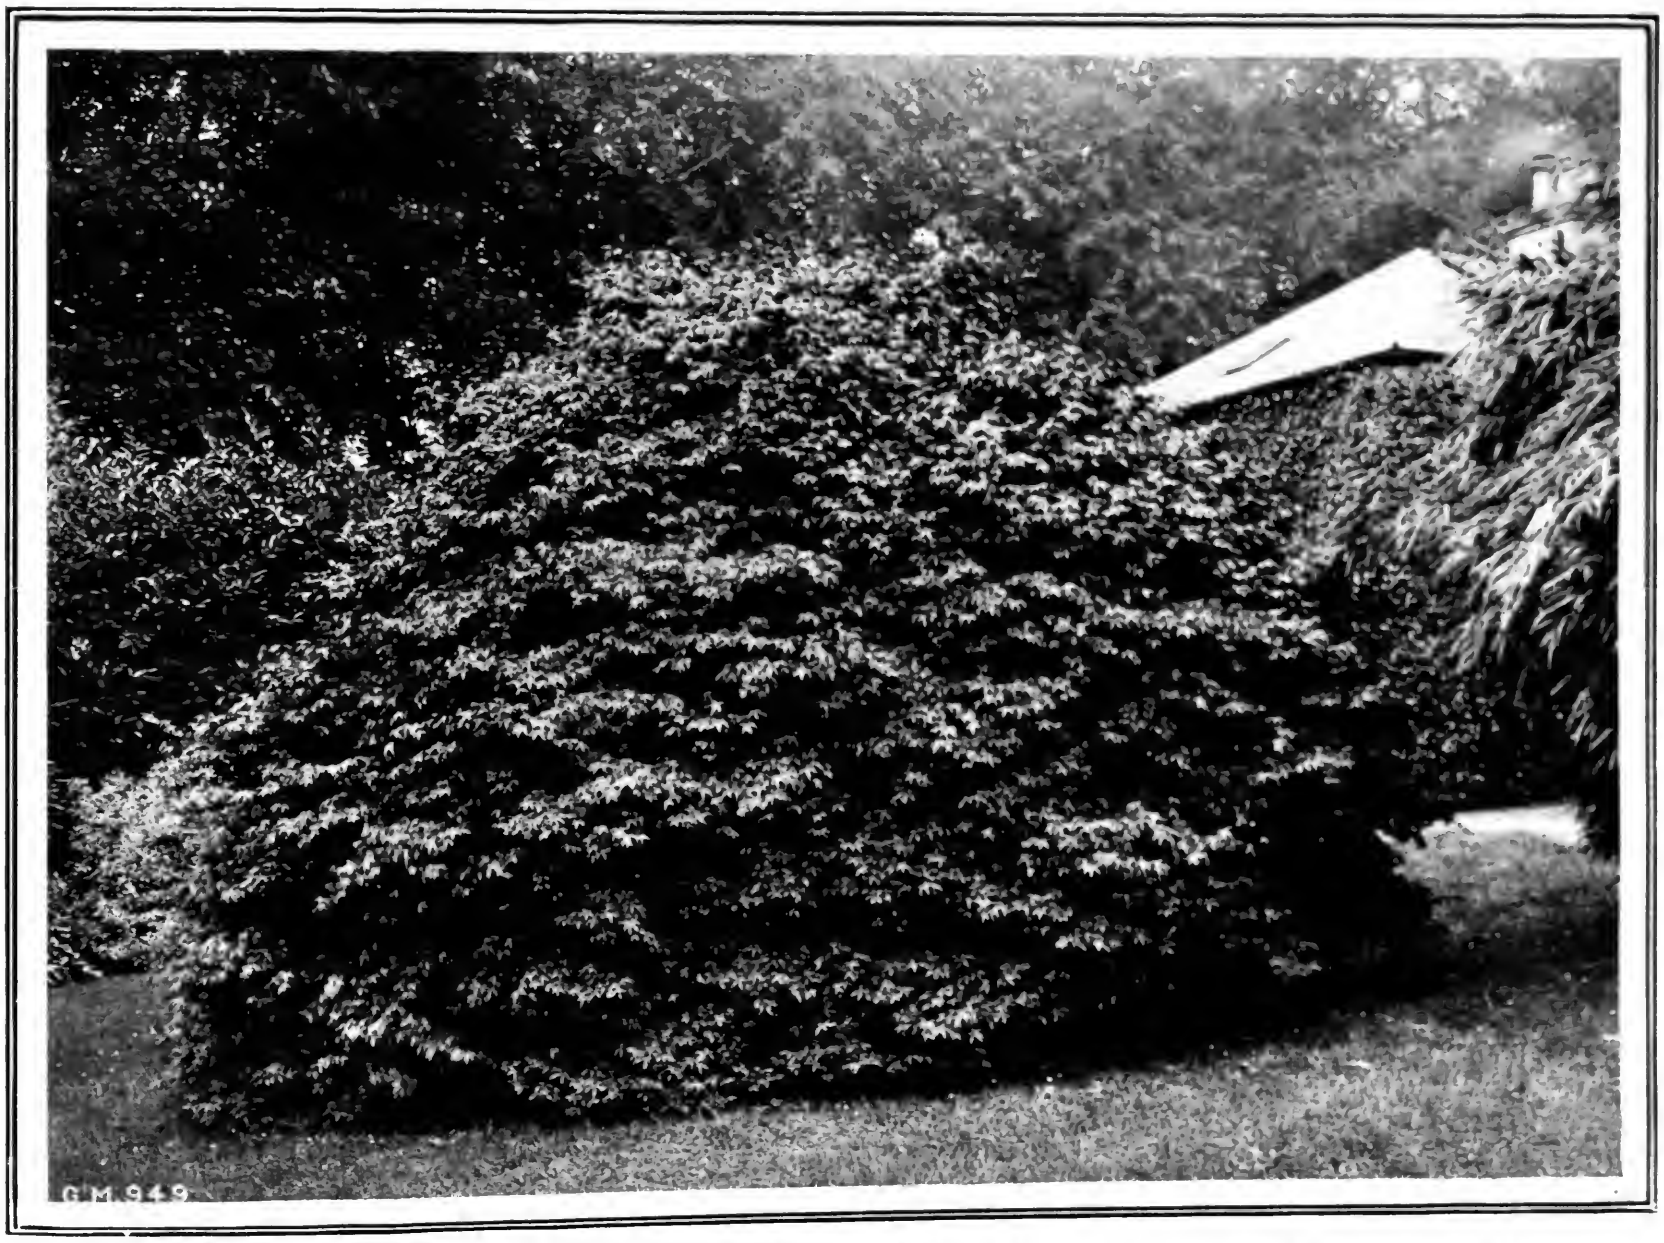
A. p. palmatifidum, an extremely elegant form, somewhat resembling A. p. dissectum, differs from it in colour, both the shoots and leaves being bright green. It is of much value, more especially as a distinct contrast to the highly-coloured varieties.

A. p. roseo-marginatum is a very pretty form, and the leaves are relatively small, and bright green, with a light rose margin.

A. p. septemlobum has leaves rather larger than those of the typical A. palmatum, which have 7-9 lobes. There is also a form known as A. p. s. atro-purpureum, with bronzy-red leaves, which is very effective, and deserves to be generally planted.

A. p. sanguineum is so distinct and remarkably effective that it deserves special attention, for the brilliant colour of the leaves, which, in large masses, as in the case of a well-grown specimen, is strikingly effective.

G. G.



A FINE SPECIMEN OF THE RED JAPANESE MAPLE AT CASTLEWELLAN, CO. DOWN.

FIRM SOIL FOR VEGETABLES.

The importance of firm ground in vegetable culture is a matter worthy of more consideration than it generally receives. Most of us have our pet ideas and fads, and no doubt we are apt to regard them through magnifying glasses, making them assume a value out of all proportion to their true merits. It is only when we glance over our neighbour's hedge, and find him turning out stuff equal to our own by methods flagrantly violating our cherished precepts, that we realise how it is possible to raise some minor detail to the eminence of an indispensable factor.

But there is nothing in the nature of a fad in my plea for firm ground in the vegetable garden; it involves a principle which must in every case be respected if the best results are to be achieved. By sowing or planting in loose soil the crop is laid open to dangers from various directions, simply because the very foremost of necessities in a rooting medium is disregarded. In their natural state, plants of the higher orders, such as we are discussing, send their roots down into the solid undisturbed earth, and

for many ages have found in it the most perfect conditions of anchorage and of growth. Now, although I admit that it is unsafe to urge too close a parallel with Nature in our dealings with horticultural subjects, I think that in the fundamental process of root-action the best soil conditions are those obtaining in uncultivated virgin earth, so far as the question of firmness is concerned. The further the cultivator departs from this standard of solidity, the further he departs from a perfect rooting medium.

But there are other aspects of soil preparation of very great importance tending to leave the garden ground hollow and loose. Soils of all kinds must be deeply dug and manured; clays must be improved by the plentiful addition of light, opening material; sandy soils must be bound together by the incorporation of pulverised clay or marl. These operations, if rightly performed, thoroughly disintegrate the staple, leaving it open to the beneficial action of frost, wind, and sunshine. Viewed solely as a preparatory stage, this looseness is highly commendable; the trouble begins when we plant upon a soil which has not had ample time to settle down and become really firm.

It would be too much to say that crops on such a soil are in danger of absolute collapse, but a few moments' reflection will show the disadvantages they have to contend against. Foraging rootlets, striking down into the soil, must needs be in closest possible contact with the moist particles of earth. They absorb their food entirely from solutions in the soil-water, and, besides this, the slightest suspicion of dryness is sufficient to destroy the tiny root-hairs by which nutriment is taken in. It is unnecessary to point out that loose soil, by the free admission it gives to the air, is likely to withdraw nourishment from the tender, newly-emitted roots, and to deprive them of their organs of assimilation at the same time. Again, the constant settling movement of the unstable ground is in itself a means by which roots are torn and mutilated. The more deeply the soil has been dug the more lasting and formidable do these several drawbacks become.

The destruction or starvation of a root here and there may not seem a great disaster, especially when a plant becomes established, but, believe me, it makes just that difference between a first-class production and a mediocrity. A check is occasioned by the tearing of the smallest piece of root, or by the loss of a single spongiole, and every check takes something from the quality and growth of the finished plant.

I believe, too, that there is a connection between hollow ground and the attacks of those malignant diseases which threaten some of our vegetable plants so sorely. Crops sown or planted in recently-dug plots seem unable to resist fungoid maladies or insect pests with anything like the same power as those put in where the ground has thoroughly settled. No doubt, this is attributable to the numerous small checks received by the roots in the unstable ground, which, lowering the standard of health, give a footing to various enemies.

These points come to my mind now the season of digging and soil amelioration is with us, and I would urge those who have trenching under hand to push on with it, in order to give the soil time to settle before planting.

We cannot get soil too solid by natural means, provided always that its mechanical character is correct, and in solidity lies one of the greatest safeguards to the health of vegetables.

J. E. SIMMS.

Elkington Hall Gardens, Louth.

DAHLIAS IN 1913.

The dahlia season just over has been, probably, one of the longest on record, for there were plenty of flowers on the plants in this district as late as November 20th. This lateness will surely assist in making the dahlia more popular than ever for garden decoration, because, where the plants were grown freely in their early stages, and planted out at the latter end of May or early in June, they commenced flowering in July. I am not altogether an admirer of the dahlia during the summer months, for it seems to me the plants are not very happy in hot, bright sunshine.

The Weather.

This season could not by any stretch of imagination be called an ideal one, for during June and July the weather was too dry, cold, and sunless for the plants to make much headway. It made watering a burden, even at the end of a hose pipe, and watering did not appear to help the plants very much. So, early in August, it seemed as though the dahlias would never reach the top of their stakes, and that we should have to view whole regiments of stakes, with a few flowers. But this was all altered early in September, for the warm nights, heavy dews, and welcome rain caused the plants to grow away as though they were taking a new lease of life, and constant tying was necessary throughout the month. I do not remember a season when there was so little damage by the wind; but this, I hear, did not apply to all districts. The absence of frosts enabled flowers to appear in competition with chrysanthemums at our autumn shows, and this was unfortunate for the latter, as they cannot compete against the brilliant colouring seen in the dahlia.

Popularity.

It has been said many times during the past autumn that the general public do not yet know the modern dahlia, and I am convinced that this is so from the remarks made at flower shows and other places. There is an idea that the dahlia is a plant which takes up an enormous amount of space in the garden, and produces heavy, lumpy flowers, quite useless for either cutting or decorative purposes; that flowering starts just before the frost cuts it down, and, above all, that it collects all the earwigs in creation! Just how long it will take to dispel all this it is difficult to estimate. The room a plant occupies depends entirely on the cultivator and the section of the flower chosen. There are dahlias that can be grown in a space two feet square, and grow only eighteen inches high. Now, as to the flowers themselves, I admit there are plenty of heavy lumpy flowers, but there are those which are light and graceful, and can be used for any decorative purpose. Even the flowering period rests, to a great extent, with the cultivation, and earwigs are no more troublesome to the dahlia than they are to the chrysanthemum, or many other garden flowers. Once the public becomes educated in the matter of dahlias I feel sure the family will become more popular.

The Duffryn Trials.

The year 1913 will long be remembered by dahlia growers all over the country in connection with the elaborate trials carried out by Mr. Reginald Cory, at Duffryn, near Cardiff. Mr. Cory is an enthusiast in all matters pertaining to horticulture, and he sought by these trials to demonstrate the value of the dahlia for garden decoration. With this end in view he planted all the varieties he could get together, and they were judged in September by a joint committee of the Royal Horticultural Society and National Dahlia Society. They were judged from a purely decorative point of view, and nearly a thousand varieties were represented. It was, perhaps, the finest collection of dahlias ever brought together, and although I am informed Duffryn was a sort of Mecca for those interested in the dahlia, and hundreds besides, it was a pity such trials could not have been seen by thousands, for there were whole beds of one variety, borders of a single section, dahlias on terraced banks, without stakes, dahlias as "dot" plants, in company with ordinary summer bedding plants, dahlias in the herbaceous borders, dahlias, in fact, in every conceivable position, and most successfully cultivated.

Other Events.

The Challenge Cup, known as the Cory Cup, presented by Mr. R. Cory to the Council of the Royal Horticultural Society for an exhibit of decorative garden dahlias, open to the trade, and a silver cup, offered for amateurs, excited the keenest interest. The traders turned out in strong force at Westminster, but the amateurs did not respond very well. Perhaps they were nervous, but I am given to understand this will not be the case next year, for there are already many stalwarts prepared to try their skill.

The National Show.

This was held at the Crystal Palace, and was well up to the average in point of entries, showing an increase on its predecessor. At the same time I do not think the flowers were quite up to the usual standard. It will be remembered that some parts of the country were deluged with rain, and swept with wind, a week before the show, and so some exhibitors were not able to stage in their usual form, while some amateurs failed to fill their entries. The improvement in the stems of the cactus varieties was a noticeable feature.

The New Varieties.

I may not be correct, but I am under the impression there was a dearth of really good new varieties. The show and fancy sorts failed to score a single award, while those in the most popular section, the cactus, certainly were not represented by so many new varieties as in former years, and there was nothing standing out beyond all else. I suppose it is now very difficult to obtain a really new colour. I also think the standard of perfection has become somewhat strained, thus making it exceedingly difficult for the raisers to obtain the coveted awards. The pompon varieties, what few there were of them, were distinctly good, and there were others in this section which might well have been honoured. Singles, too, were few in number, although some exhibited quite new shades of colour.

The pæony-flowered section continues to advance in spite of its critics, and is making far greater headway than some care to admit. The improvement in the stems was most marked, while the new varieties showed a greater refinement than their parents. The latest aspirant to popular favour, the Collerette dahlia, bids fair to take its place in the dahlia world in no mean spirit. This section secured more honours than any other. The varieties are improving rapidly, not only in colour, but in form and stem. The decorative varieties are not happily classed; some produce huge flowers, while others are small, yet they are all lumped into one section, and require re-classification.

BARR'S SPECIAL BULB PLANTER
Rd. 548091.

Specially designed for planting Daffodils and other bulbs in grass. This tool cuts and lifts a clean circular piece of turf, which is released from the cup when the second hole is made, and lies ready at hand to fill in the holes when the bulbs have been put in, it being only necessary to remove a little of the soil from the bottom of the sod. By its use a large quantity of bulbs may be planted in a very short time, and without the least disturbance of the sward. The cup is manufactured from high-class hardened steel, and always carries a keen cutting edge. 10s. 6d. each.—BARR and SONS, 11, 12, and 13, King Street, Covent Garden, London.

THE LOWFIELD NURSERIES.

The art, science, and craft of gardening are united in a remarkable fashion in the extensive business conducted by Messrs. J. Cheal and Sons at the Lowfield Nurseries, Crawley. For many years past this firm has been steadily developing its landscape gardening department, until now it has works on hand in various parts of the United Kingdom and Ireland, and in some cases these are very extensive and important operations. Garden planning has been made a great feature, and the preparation of designs and plans now occupies a considerable staff, and proves one of the most interesting features of the nursery to anyone privileged to inspect it. With the growth of this department the provision of garden furniture became an important matter; eventually the Messrs. Cheal added a large workshop for its manufacture, and are now able to meet all demands for summer-houses, tea-houses, garden seats, and tables of all shapes and sizes, screens and treillage, gates, fancy fencing, etc., etc., and a few moments watching the men at work gives one a very good idea of the distinct advantage this addition must be to the firm.

During the late autumn the large and well-devised fruit room attracts attention, and its well-filled shelves testify to the influence of good cultivation and fresh air upon fruit production. The offices and methods followed to ensure promptitude in dealing with correspondence and orders all point to a large business conducted on the most up-to-date lines. Mr. Joseph and Mr. Alex. Cheal, with Mr. J. Cheal's two sons, take charge of various departments, but the arrangement is such that all things work together for the good of the firm and of the customers.

Fruit Trees.

Fruit tree culture has always been a large business with the Messrs. Cheal. Some years have elapsed since the writer visited the Lowfield Nurseries, but during that period the demand for hardy fruit trees has steadily increased, and now the firm has from 30 to 40 acres under their culture, and a finer lot of trees it would be a very difficult matter to find. Having seen the new Crawley Beauty apple, we were anxious to find out what kind of a tree this variety made. So far there is every indication of its success as a standard, and the original tree in the locality is further proof. It is a free-growing variety, makes a capital bush, and buds up so well all along the stems that it is also one of the best of apples for cordons. A fine late fruit, it is also a late-flowering variety, and is self-fertile, as it blooms when practically all other varieties except Court Pendu Plat, are over; indeed, in most seasons, the flowers fall about the second week in June. Altogether there seems very good reason for selecting Crawley Beauty as a variety well worthy of trial.

Cordon apples and pears are splendidly managed here, and trained trees of all descriptions are extensively grown. Customers can inspect the trained trees with the greatest of ease, as all are planted in regular, straight lines, instead of being trained just as and where they developed in their earliest stages of growth. Although the extent of the nursery is so considerable that anything like a full inspection is an arduous task, it must be allowed that the grass walks, and the regular blocks and lines of fruit trees, roses, etc., render inspection both pleasant and interesting.

In passing along the apple quarters we noted grand lots of Lord Derby, a variety that does well as a cordon; Lane's Prince Albert, very fine on the free stock as well as on the Paradise; Bramley's Seedling, notably fine in standard form; Grenadier, one of the best selling apple trees; Newton Wonder, splendid in every form, and superbly cropped here; Blenheim Orange, Bismarck, Emperor Alexander, Peasgood's Nonsuch, Chas. Ross, Rival, and other popular apples in quantity and in various forms of training.

Of special interest is the plot devoted to pyramid and bush trees, where about three trees each of a number of the best varieties are cultivated as though in a private garden. Some of the trees are of considerable size, and were planted fourteen years ago; others are small, and represent such new varieties as Rev. W. Wilks, Wm. Crump, etc. But the way the older trees crop, with every branch like a cordon, is an eye-opener. In most cases the branches had to be tied to each other for mutual support, and in several instances stout wooden props were requisitioned to support the heavy crops. Lord Derby, Jubilee, The Queen, Lane's Prince Albert, Schoolmaster, Sandringham, Newton Wonder, Bismarck, Gascoyne's Scarlet, and Chelmsford Wonder, are varieties that everyone would want to plant if they saw the trees carrying their wonderful crops as the writer saw them at the Lowfield Nurseries.

There has been an increasing demand for stone fruits of late, and the Messrs. Cheal are prepared to meet it, as they have peaches and nectarines of first-rate quality, well trained, and with capitally ripened wood; plums, too, are excellent, and cherries especially good.

Ornamental Trees and Shrubs.

Quite naturally, with increasing activity in the landscape department, the Messrs. Cheal have added extensively to their collection and stock of ornamental trees and shrubs. Whether we do or do not like topiary work, the fact remains that clipped yew and box are in great demand in connection with the more formal portions of newly-designed gardens, and so all kinds of quaint designs are manufactured at Crawley, and their evolution can be watched, if need be, for the firm has found so much difficulty in securing the right kind of tree at the right moment that it has been making its own for some years, and now there are all designs, from footballs to alligators, from teddy bears to suffragettes, from chairs to churches, and from barges to galleons and steamboats.

There is no intention of turning this notice into a catalogue, as the Messrs. J. Cheal and Sons issue departmental catalogues, which are models of conciseness and restrained descriptions; but a few of the ornamental trees and shrubs which arrested attention may be mentioned, and first of all there is Platanus Suttneri, a form with beautiful cream-coloured leaves, prettily blotched with green of several shades. It is a very handsome standard tree that deserves attention. Rhus typhina laciniata is not new, but its merits as a foliage plant are not yet fully understood. Cotoneaster thymifolia, with smaller foliage than C. microphylla, promises well as a small shrub for the rock garden; while Sequoia sempervirens albospica is a quite showy tree of considerable size. Standard trees for avenue planting are especially good, as they stand out clearly above lower subjects, and have well-developed heads; the Cornish elm, Acer colchicum, silver lime, the finer thorns, and sycamores appeared to be special lines.

Conifers are a great success, and frequent transplanting is followed so that in the fairly heavy soil at Crawley the root system becomes a dense rounded mass of fibres. Conifers for specimens in the garden and pleasure grounds are as much in evidence as the batches of various sizes for plantation work and for hedges. Cedrus atlantica glauca is finely represented, and yews are grand, including a block of plants clipped closely on two opposite sides so that when transplanted they make a dense hedge immediately There are also fine collections of ceanothuses, berberis, ornamental crabs, rhododendrons, mollis azaleas, and heaths.

Dahlias.

The roses, grown in quantity, must be passed over with merely a mention, although there must be hundreds of thousands. The dahlias deserve a few words, because the Crawley firm has for so long been intimately connected with the advance of these popular flowers. Their own introductions among pompon and single varieties are well known to fanciers, and there are those who appreciate the lowly-growing Tom Thumb series of garden varieties. The latter strain possesses a rather stiff habit, and will have to give place to the Mignon varieties, which is wonderfully free-flowering, and carries single blooms of great beauty on plants from 1½ to 2ft. high, furnished with very neat foliage. Here, surely, are dahlias for small gardens, and just the dahlias for bedding, or for association, as groundwork, with the taller cactus, decorative, and paony-flowering sorts. These dwarfs need no staking.

A wonderful sight are the dahlias at Crawley, as, besides pot roots and stock plants of special kinds, there were 2,500 named specimen plants planted in great blocks according to their sections, and a further range of 1,200 seedlings on trial. Viewing the several sections, block by block, one had to confess that for garden decoration the order of effectiveness appears to be collerettes first, paony-flowered and decorative sorts second, pompons third, shows and fancies fourth, singles fifth, and cactus varieties "also ran." The most effective and floriferous collerette sorts were Henri Farman, Maurice Rivoire, Diadem, and Mdme. Porrier, but there were others of almost equal merit Coronation, Mrs. Greville, Freedom, Niobe, Selma, Queen of Pinks, Mrs. Paton, and Mrs. Lonsdale were the best of the cactus sorts. All the pompons were good for garden decoration, although our own taste selected Nerissa, Regulus, Bacchus, Glow, Ideal, Jessica, Darkest of All, and Elsa The rounded florets of the modern single varieties were very pleasing, and if only the blooms lasted a little longer it is doubtful whether other sections would stand much chance in our gardens, and it is just here that the collerette varieties have the advantage. However, varieties like Vesuvius, Mrs. Joynson Hicks, Glencoe, Elaine, Miss Morland, Flora, and Owen Thomas are so meritorious that they are already popular

The seedling dahlias were wonderful, even in October, and we assisted in the selection of several sorts for further trial. The new decorative variety named Reginald Cory, red, white tipped, was very showy here, as at Duffryn. Near by was the old Glare of the Garden, not to be despised even now in colour schemes; and not far off was the new Crawley Star, a lovely semi-double pink dahlia with crimson bases to the petals; it is lasting, very graceful, of beautiful colour, and wonderfully free-flowering. A white counterpart of this distinct form has now been raised, and it promised to be as good as its forebear.

The half has not been told, but one must stop somewhere, and the glory of the dahlias may well be our last thought. C. K.

Potatoes.—The sets for forcing should now be placed in shallow trays or boxes, and be covered lightly with finely sifted leaf-mould; put them in a newly-started peach house to sprout. They may then be potted up in 8-inch or 10-inch pots, or in heated pits. Select for this purpose quickly maturing varieties, and those which make but little top growth. Sutton's May Queen and Sharpe's Victor are two excellent varieties for this purpose. It is of the utmost importance that the sets should have young shoots, slowly and sturdily made, before planting takes place.—W. MESSENGER, Woolverstone Park Gardens.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

MEXICAN LÆLIAS.—There are numerous species, and several natural hybrids, among the Mexican lælias that are easily cultivated, and suitable for the supply of choice bloom during the months of December and January. Where a small structure can be set apart for the cultivation of these lælias and other light-loving plants, there is little difficulty in producing satisfactory results, and, although some of the kinds may not flower so satisfactorily when grown under the same conditions as the cattleyas or in an ordinary plant stove, they are generally found to grow very well, even under such treatment.

L. AUTUMNALIS AND L. ANCEPS are the first of this section to commence flowering. The plants are usually imported in strong masses, and are procurable for a moderate outlay. There is considerable variation in colour, but the pure white L. autumnalis alba is a very rare plant. The coloured varieties of L. anceps immediately follow with their flowers, and they always succeed and usually flower well when grown under the same cultural conditions as the cattleyas, and given a position in the lightest part of the house. The white varieties, with the exception of L. a. alba, L. a. Dawsoni, and the pale L. a. Percivaliana, do not flower so freely, unless they are exposed to plenty of strong light. In the immediate neighbourhood of London and smoky districts, where the conditions are so detrimental to expanding flowers in general, the culture of these lælias is a hopeless business, as the least trace of fog injures the flower buds, and they rarely give satisfaction.

L. SUPERBIENS produces a flower scape several feet in length with a cluster of flowers at the apex. This species requires plenty of light, and should not be disturbed at the roots more frequently than is absolutely necessary. It always flowers best when baked by the sun and root-bound. L. albida is another species that flowers about the same time as L. anceps; its fragrant, white flowers are always appreciated. The natural hybrid, L. Gouldiana, derived from L. autumnalis and L. anceps, is exceedingly variable, and in its best dark-coloured forms it is one of the most attractive of the Mexican orchids. The miniature L. rubescens flowers later, and, when large specimens flower, it is very attractive. Plants of all these kinds must be carefully watched for insect pests.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

WINTER-FLOWERING CARNATIONS.—These are flowering very freely this season, owing, no doubt, to the exceptionally mild weather. Water the plants with care, but do not allow them to become really dry. Rain-water should be used for this purpose whenever possible. The plants are now well rooted and full of growth, so stimulants may be afforded frequently. Keep a sharp look-out for red spider, as unless this pest is checked in its early stages it will do considerable injury. Give plenty of air during favourable weather, always remembering that a close, stuffy atmosphere is favourable to the rapid development of carnation rust. If the main batch of cuttings has not been put in, no time should be lost, as the growths are in splendid condition. The weather has been favourable for the Malmaison varieties, as it has been possible to keep the ventilators wide open both day and night. Afford water sparingly, keeping the plants rather dry. If there is any sign of rust, dip the plants in one of the specifics recommended for this troublesome disease. The operation should be repeated every two or three weeks until the foliage is clean.

ANNUALS FOR POT CULTURE.—These must be repotted as required, and kept growing slowly in a cool house as near to the light as possible. Clarkias must be carefully handled for the next few weeks, as they are very subject to damping. Stopping is sometims recommended for clarkias, but I find they do better if allowed to grow unchecked. Aphis will do considerable damage to schizanthuses and clarkias, but a light fumigating is sufficient to kill this pest. Mignonette, which was sown in small 60-size pots in the autumn, should be potted into 48's in a compost of loam, leaf-soil, and coarse sand.

CYCLAMENS.—The early batch is now in full flower, and to keep the plants in good flowering condition over a long period requires careful treatment. Every favourable opportunity must be taken to admit air, but this must be done with due consideration to the conditions prevailing outdoors. Cyclamens are now in need of plenty of stimulants, but watering must be done with care, keeping the centre of the plants as dry as possible. Dead flowers and leaves must be regularly removed, and should be pulled out from the base to prevent damping.

HUMEA ELEGANS must be carefully handled for the next few weeks. I find the hardier they are grown the less liable they are to fail. During the winter months they should be stood on a cool ash or gravel base near the glass. If repotting is necessary it must be carefully done, and the plants must afterwards be watered with extreme care.

RICHARDIAS.—These appear to be flowering much earlier than usual, although they have been grown under very cool conditions. They are not, as a rule, required until the chrysanthemum season is over, therefore they must be retarded as much as possible. A house with a northern aspect is best for this purpose, and fire-heat must be given only to keep out frost. Now that the pots are full of roots, stimulants must be afforded more frequently, and at increased strength. —E. HARRISS, Lockinge Gardens.

HARDY FRUITS.

ORCHARDS.—If a constant supply of good clean fruits is to be expected from the orchard, the heads of the trees should be kept well open, so that both light and air can reach the interior. If the orchard is grassed, keep the grass grazed very closely, and feed liberally at intervals with rich farmyard liquid manure, especially if the soil is porous and well drained. Many of our old orchards where the fruits are poor, and the crops light, might be greatly improved by attending a little more to the roots, and thinning the branches annually. When pruning, first remove all crossing and interlacing branches, and it is better, when tackling large, neglected trees, to have two men to do the work, one using the saw, and the other directing which branches must be removed. When the pruning and thinning are completed, scrape the trunks and dress with lime, or spray them with caustic alkali according to directions given. All orchard and fruit plantations should be thoroughly drained, and screened from the north and north-east winds; belts of damson trees will answer for screens, and will also be profitable; plant them rather closely.

STAKES AND TIES must be thoroughly examined annually and made good, for if this work is overlooked much injury may follow. Keep the varieties correctly, named, and see that tree stems are well protected against sheep, hares, rabbits, etc. Mulch the roots of all newly-planted trees with a little strawy manure, and heavily top-dress older trees with rich farmyard manure, poultry manure, or anything that will assist them.

RASPBERRIES.—These root very close to the surface, so that deep digging among them must not be practiced. Good surface dressings of sweet loam and decayed manure along the sides of the rows will prove very beneficial to the old shoots and canes, and help to increase fruitfulness the following year. After tying out the canes, prick up the surface soil with a fork. The formation of new beds should also receive attention. Where the old beds are failing, select a good site, trench deeply and break up the subsoil. In the warmer districts raspberries succeed admirably when growing on a cool north border.

FRUIT ROOM.—Keep a sharp look-out for decaying fruits and remove them at once. When only just commencing to decay the fruits may be made use of for cooking purposes. Apples are keeping rather badly this year, excepting those allowed to hang on the trees until very late. With us, the fruits began to drop early, before they were fully matured.—H. MARKHAM, Wrotham Park Gardens.

THE KITCHEN GARDEN.

SEAKALE. It is the practice with many cultivators to force seakale on the outdoor beds, and, where it is possible, to procure a quantity of good oak or beech leaves to make up a mild hotbed. This method generally proves successful, and the quality and size of the heads is usurpassed under any other method of forcing. When raking leaves or rough grass the mixture of grass and leaves will give a sufficient temperature; but with leaves only it may be necessary to add some stable manure to obtain the required heat, which should be of a mild nature throughout, as an excess of heat will cause too rapid growth and thin, spindly heads. The seakale pots may be placed over the crowns some days in advance of the fermenting material. Stout sticks should be inserted to test the heat of the bed; snow or heavy rains will quickly affect the heat, and it may be necessary to add more stable litter to correct the deficiency. The permanent beds of seakale should have the foliage cleared away, and the surface soil well stirred with the hoe. A good dressing of kainit, as advised for asparagus, will prove beneficial.

ASPARAGUS.—As the season advances the crowns more steadily respond to mild forcing; further supplies should be introduced according to demand. The crowns should be lifted and placed on a mild hotbed made up in a pot where heat can also be obtained from hot-water pipes. When the heat of the hotbed has fallen to about 80 degrees, plant the crowns thickly together on a thin layer of soil, and cover them with another layer; any soil of a light nature will be suitable. Water with tepid water, maintain a moist atmosphere, and a temperature not exceeding 60 degrees.

EARLY CARROTS.—An early supply of small, succulent roots is much esteemed, and to provide these, a hotbed should be made up of leaves and stable manure. Ordinary wooden frames are suitable if the lights are well glazed and in good condition to prevent drip. Where the subsoil is porous it is a good plan to dig out a wide and deep trench, and in this place the fermenting material, making up the bed 18 inches above the ground level; tread the whole firmly as the work proceeds, place the frame in position and fill in with 6 or 7 inches of fine, rich soil. As soon as the heat has settled down to a comfortable warmth sow the seed, in drills 7 inches apart, for such varieties as Inimitable Forcing, Early Gem, and the well-known French Shorthorn type. As soon as the young plants are visible, admit air to the frame according to the condition of the weather. Steady, sturdy growth must be aimed at.—W. MESSENGER, Woolverstone Park Gardens.

TRIAL OF DECORATIVE GARDEN DAHLIAS AT DUFFRYN.

To the splendid dahlia trials carried ont at Duffryn this year on behalf of the Royal Horticultural Society and the National Dahlia Society we have already referred at some length, and we have published illustrations of certain features of the trials. The official report, drawn up by the two societies, has now been issued, and we have much pleasure in publishing such an interesting and instructive account:

By the kindness of Mr. Reginald Cory, these trials took place in his charming grounds at Duffryn to demonstrate the value of the dahlia as a decorative garden subject, and with this end in view all the rasiers in this country and some on the Continent were invited to send plants of every section of the flower they deemed to be valuable as decorative garden plants. The response was far in exces sof all anticipations, for nearly a thousand distinct varieties were sent in, some as pot roots, others as green plants, the whole number mustering between seven and eight thousand plants, truly a gigantic total; and when it is remembered what a strong point it is to make an early start and grow on without a check, so as to ensure early flowering, one can imagine how this vast number must have taxed even the glass resources of Duffryn, especially as the majority of the plants were potted on as they required it into six, seven, and eight-inch pots.

The trial was quite unique, inasmuch as it differed from the row-after-row type of trial, for they were planted in a series of gardens, in beds, on borders, as bank plants, and even as "dot" plants for summer bedding. The various sections were planted together as far as possible, while the shades of colouring were also associated harmoniously; the varying height of the plants was also studied, the whole producing an effect absolutely different from the usual trials of such subjects. The cultural details were more simple, for the soil appeared to be a good holding loam, which had been deeply cultivated, a light dressing of pit manure applied, and at planting time each plant was placed in a station of sifted potting mould. The necessary support to the plant was a single stake, to which the growths were looped up; thinning out or disbudding was strictly forbidden, so that all the varieties in their respective sections were on the same plane.

This briefly sums up the cultivation of the plants in this trial, except, of course, the watering of the plants necessitated by the dry season during their growing period, which was never neglected, needless to add, with the result that when visited by the Joint Committee of the two societies on September 3 and 4 they presented a glorious display, which called for unanimous thanks to Mr. Cory and for unstinted admiration of the excellent results achieved.

The cactus section was the largest in point of numbers, there being approximately two hundred and fifty varieties. They were, however, in the opinion of the committee, the least satisfactory section, for numbers of them did not possess the faintest conception of being decorative garden plants. As a consequence, only thirty-three were considered worthy of award. It should be added, however, that other varieties would no doubt improve at a later date.

Next in importance, as far as numbers are concerned, was the pæony-flowered section. This was represented by about two hundred varieties, and as a mass of colouring the plants were exquisite, but their unequal heights rather told against them, as far as the general effect was concerned. This might be avoided if the seasons could only be gauged, as the growth of individual varieties depends so much on the weather. This trial, however, demonstrated quite clearly that the newer forms possess better stems and more lasting flowers than those raised earlier. Thirty-two varieties secured the approval of the committee.

The collerette section was represented by about one hundred and fifty varieties, a formidable list for such a late aspirant to public favour; still, at the date of inspection they produced the greatest impression, for they were literally masses of flower, due doubtless to their free-flowering propensities, shy varieties being quite rare in their ranks. However, only twenty-three varieties were honoured.

The decorative section is very difficult to define, consisting as it does at the present time of all those varieties which cannot be placed in any other recognised section, and in this trial many large-flowering varieties had been sent, which would be handsome for vase decoration, but, as garden decorative plants, belied their description. Many were evidently late-flowering varieties, and quite unsuitable for such a trial. Nearly a hundred varieties were represented, but only twelve met with approval.

The single section produced a fine effect. There were about a hundred varieties, and at the time of inspection those were quite in their best form. Sixteen varieties were recommended by the committee.

The pompon varieties were represented by about sixty kinds, which were much admired for their decorative effect. These little Lilliputians had, however, overgrown their allotted space, and, unlike the other sections, were somewhat crowded. Nevertheless they secured twenty-six recommendations, the highest percentage in the whole trial, except in quite the minor sections.

The show and fancy varieties totalled fifty, and some of them, though somewhat formal when compared with other sections, were undoubtedly highly decorative as garden plants, and ten varieties (most of them old ones) secured the necessary number of marks for an award.

The pompon or miniature cactus varieties found the soil at Duffryn much too congenial for their requirements, and in most cases had produced flowers beyond their normal size. Five varieties, however, were recommended out of a total of twenty-five entrants.

The section entered as bedding varieties was rather misleading, as it included nearly all the types; the five, however, selected by the committee, were all excellent in their respective classes, though there were plenty of forms in the other sections that would be equally well placed under this category.

The Mignon section was quite a small collection, but a very noteworthy one, the flowers single, and growing about eighteen inches high, with bright, well-defined colours, each flower carried erect; a very fine section for bedding or massing purposes.

The giant single varieties did not meet with favour, for, although their individual flowers are handsome, they appear to lack the freedom so essential to decorative garden plants.

While the Star dahlias did not on this occasion secure the support of the committee, they certainly produced a blaze of colour in the garden, though of a somewhat bizarre character.

The Parisian singles and anemone types were not, as a whole, sufficiently advanced in growth to judge of their merits, with one exception. The continental varieties arrived so late that they had made little growth, and were not in flower on September 3.

(To be continued.)

HORTICULTURE AT THE ANGLO-AMERICAN EXPOSITION, 1914.

The Anglo-American Exposition, which will be held at the White City, Shepherd's Bush, next year, has for its object the celebration in a fitting manner of the hundred years of peace and progress between the English-speaking peoples since the Treaty of Ghent in 1814. It has been felt that no more appropriate means of celebration could be adopted than a magnificent joint display, showing the vast gains which have accrued to mankind through this peaceful development of Great Britain and the United States of America during the past century.

As becomes an exhibition illustrative, in the fullest possible sense, of the activities of two great nations famous for the prominent part they have taken in the advancement of the gardening art in its varied aspects, demonstrations of both American and British horticulture are being organised on as comprehensive a scale as possible. From what has already been accomplished, it is believed that these demonstrations will be equally remarkable for their beauty, interest, and usefulness, and will prove a great source of attraction to visitors from both sides of the Atlantic.

This section of the Exposition is being organised by the Committee of Horticulture, Arboriculture, and Forestry, which includes among its sixty members the foremost horticulturists, arboriculturists, and forestry experts of the present time, who have also had much experience in the organisation of exhibitions of the highest class. The committee has already made considerable progress, and formulated a scheme which there is good reason for believing will ensure a representation of horticulture, arboriculture, and forestry worthy of the two great nations interested.

Adequate provision has been made for the displays of rock and water gardening, which have of late years attained to so high a state of development, more especially in this country. A large area on the western side of the grounds will be placed at the disposal of those who are specially interested in this fascinating branch of the gardening art. Hardy herbaceous plants, now so popular with all classes of the flower-loving community, will not be less liberally provided for, and the spacious Court of Progress has been allotted to them and to English formal gardens and rhododendrons, and here the firms who devote special attention to these important classes of plants will show their taste in arrangement and skill in cultivation.

Roses, in view of their importance and popularity, will have much space devoted to them; and under the scheme the Elite Gardens will be almost wholly occupied by these fragrant flowers. Ornamental trees and shrubs, which have had so many valuable additions made to them, as the result of the explorations in Western China within recent years, should also constitute a great feature of much interest and usefulness. Indeed, arrangements are being made for the representation of many other classes of plants that can be successfully grown in the open during the summer months.

Forestry, which is now being recognised in this country as of immense importance, both to landowners and the general community, is receiving special attention, and the scheme that is now engaging the attention of a special committee of experts will, it is fully believed, ensure an adequate representation of the varied aspects of this great industry.

Four conferences will be held in the course of the summer, and as promises of support have already been made by the leading societies identified with the special subjects, these should be highly successful. These conferences are: Perpetual Carnation Conference, at the end of May; Hardy Plant Conference, about the middle of June; Rose Conference, at the end of June; Carnation and Sweet Pea Conference, towards the end of July;

Forestry Conference in August; and a Fruit Conference in September.

We may add that Mr. Owen Thomas is the Hon. Secretary of the Horticultural, Arboricultural, and Forestry Committee, and he will gladly furnish any information regarding the work and operations of his committee. Letters should be addressed to him at the Anglo-American Exposition, Shepherd's Bush, London, W.

AURICULAS.

In somewhat belated reply to Mr. Gibson's note in the "G.M." of October 18, I may say that it was no part of my object in writing to draw attention to little-known, expensive, or unprocurable novelties, nor was I writing for the information of auricula specialists.

My idea was merely to jot down a gossipy, timely kind of note on the flower of which I am fond, based on the appearance of my plants at the time of writing; and, incidentally, to give a list of decent, cheap, robust varieties that any beginner could scarcely fail with.

Wm. Smith and the other varieties Mr. Gibson mentions may be—and I hope they are—all his fancy pictures them, and the Collier's Grey-edge may be as good as George Lightbody; but if these cannot be obtained, or have yet to gain an assured place in the auricula world, what would be the use of my mentioning them?

It is nearly forty years since I first began to take an interest in auriculas, and I have seen, during that time, hundreds of novelties that were going to beat the varieties I named, but, for one reason or another, they have not done so.

It is certainly news to me that no one dreams nowadays of staging Ruby; it is a flower I do not like, but it will grow and increase well, is fairly correct, and the usual run of amateurs cannot yet safely dispense with it.

I did not mention Robert Traill, and I am not fond of Beauty or Acme, but they are the best and cheapest of the white-edges that will grow and increase easily. At the London show this year I noticed that Acme carried off the whole of the prizes in the class for single plants. At the same show Mr. Gibson staged Smiling Beauty and Rev. F. D. Horner, which are more obsolete varieties than any I mentioned. I was, at the same time, pleased to see that Smiling Beauty still existed, as it was raised here where I live, and if Mr. Gibson has a bit of it to spare I shall be glad to have it.

I do not know what length of experience Mr. Gibson has, but Messrs. Horner, Douglas, and Simonite can hardly be described as growers of twenty to thirty years ago, as they have all died recently.

In conclusion, I may say that I have seen, in past years, greens that beat Mrs. Henwood, greys that were as good as George Lightbody, and whites that were better than Acme; but where are, for example, Horner's Greyhound, Horner's Magpie, and Barlow's President Royds? New varieties are of no practical use unless they have certain properties; they must be good growers, increase well, and be fairly constant at blooming time. The Collier's Grey, though as good as George Lightbody, if it is "growing, very, very slowly, and will not increase," as Mr. Gibson writes, is of no practical use.

I welcome Mr. Gibson's "dressing down," as he calls it, but fail to see where he scores.

JAMES W. BENTLEY.

Stakehill, Manchester.

Crotons, Dracænas, and Acalyphas, which have been used for house decoration, and are past their best, may be shortened, cleaned and returned to the stove for stock purposes. Keep them rather dry at the roots; they will soon "break," and by early spring will afford a useful lot of growth suitable for cuttings.— H. Prime, Hatfield House Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Perpetual-Flowering Carnation Society.

At the close of the show on December 3 about forty members of the society assembled in the Lecture Room at the Royal Horticultural Hall, for the annual general meeting. Mr. J. S. Brunton presided. The report was taken as read, but the Chairman reviewed the work of the year, and said they had reason to congratulate themselves on the excellent progress made. Much of the credit was due to the carnation itself, which was undoubtedly forcing itself into favour everywhere. The wonderful increase in the number of registered varieties indicated that both trade and amateur growers were paying much attention to the delightful work of raising seedlings. The increase of membership was highly satisfactory, and he urged all members not to relax their efforts in securing more members. The Chairman then drew attention to the fact that they had two Belgian members with them, and he tendered a hearty welcome to both M. V. Bouchenooghe, of Ypres, and M. E. Draps Boudry, both of whom were large growers of carnations. They also had had the pleasure of the company of Mr. Collard, gardener to the King of the Belgians, that day. The Chairman also referred to the magnificent George Monro, jun., Cup, which had been won by Mr. C. Engelmann.

Audited, November, 27, 1913,
RICHARD PINCHES.
E. F. HAWES.

The acceptance of the report was then proposed by the Chairman, seconded by Mr. W. A. Sherwood, and carried unanimously.

The Treasurer, Mr. Lawrence Cook, then read the financial statement, which was accepted as being very satisfactory.

Mr. M. Todd then proposed a vote of thanks to the retiring officers, which was seconded by M. V. Bouchenooghe, and carried unanimously. Lord Howard de Walden, as President, and all the vice-presidents, were re-elected. Mr. W. A. Sherwood and Mr. Tandevin moved the re-election of Mr. J. S. Brunton as chairman of committee, and the motion was carried with applause. The Chairman briefly responded, and said it was a pleasure to be associated with such a harmonious committee as the P.F.C.S. always had. During his association with the society, there had never been any strong dissension, but everything worked as harmoniously as could be desired. Mr. W. E. Page proposed, Mr. A. F. Dutton seconded, and it was carried that Mr. W. E. Wallace be re-elected vice-chairman.

On the motion of Mr. Wallace and Mr. C. Engelmann, Mr. L. J. Cook was re-elected treasurer. (Carried.) Mr. Cook returned thanks for the honour, and said that since Mr. Weston had become secretary his own duties had been greatly lightened. Mr. R. F. Felton and Mr. H. T. Mason moved the re-election of Mr. T. A. Weston as secretary, and each paid a tribute to Mr. Weston's ability and energy. The proposal was carried with applause, and Mr. Weston thanked the members for their appreciation of his services, and for the honorarium voted him. The duties were by no means light, but the committee and members generally had been exceedingly kind to him, and now he had fully gripped the work he ventured to promise that he would not be found wanting during the ensuing year. Mr. E. F. Hawes was re-elected show superintendent, and the ballot for members of committee resulted in the election of Messrs. A. F. Dutton, C. Engelmann, F. Fitch, F. W. Harvey, W. A. Sherwood, W. Lawrenson, Percy Mount, A. Smith, H. Taudevin, and W. Holder—all to serve until 1916.

The Chairman then referred to the subject of affiliation. From time to time this had been discussed, but nothing had been done, and it was now felt that the present was an opportune time to deal with the subject. Mr. T. C. Loosemore proposed that the General Committee be empowered to draw up a scheme whereby horticultural societies throughout the country could become affiliated for a fee to be decided upon; such societies to receive a medal, or some suitable prize, to be competed for by their own members. Mr. R. F. Felton seconded the motion, and proposed that the fee be £1 1s. Mr. A. E. Usher strongly opposed a fee of one guinea, and said the P.F.C.S. did not want a few select societies on its list but many of the small societies up and down the country. The big societies could look after themselves, and so he advocated a fee of 10s. 6d. Mr. F. W. Harvey supported Mr. Usher, and, as Mr. Felton withdrew his amendment, the original proposition was carried, and the Chairman said that 10s. 6d. would be the minimum fee for affiliation.

M. V Bouchenooghe, the senior Continental member, said he and his friends were amazed at the wonderful show they had seen that day. The quality of the blooms gave them much encouragement to go on with their work in Belgium. He appreciated the honour of being asked to act on the jury, and referred to Mr. J. S. Brunton, who, whenever he came to Belgium, talked carnations all the time, and it was due to him that they had such a wonderful display of carnations at the Ghent Show in May last, for which Mr. Brunton had been specially thanked by the King of the Belgians, who had since become a keen carnation enthusiast.

Mr. E. Draps Boudry, briefly endorsed his friend's remarks, and announced that he desired to present the society with the sum of two guineas, to be offered as a prize for

twenty-four blooms, an offer received with applause.

Mr. W. H. Page proposed a vote of thanks to their Belgian friends. He himself had been impressed by the unbounded hospitality shown when visiting Ghent, and anything the society could do to further the interests of carnations on the Continent he hoped they would do. Mr. Harvey, in seconding the motion, expressed the pleasure of meeting Mr. Bouchenooghe, who, he had learned, was an old Kewite. He hoped that the next dinner of the P.F.C.S. would not fall on the same date as the Kew Guild dinner, as he wanted Mr. Bouchenooghe to be at the Kew Guild celebration, while he himself wanted to be at the P.F.C.S. dinner. The proposal was carried with much applause.

A vote of thanks to the chairman brought the meeting to a close.

National Chrysanthemum Society.

This society held its winter exhibition at Essex Hall, Strand, London, W.C., on December 10, and, for so late in the season, the display was a charming one, the flowers fine and the colours especially good. The competition in the several classes was not very keen, but some non-competitive displays atoned for any failure here.

The Floral Committee granted First Class Certificates to Essie Walters, a terra-cotta single, from Mr. P. Ladds, Swanley Junction; to Commodore, a crimson single, from Mr. Thos. Stevenson, Woburn Place Gardens, Addlestone; and to Heston Pink (also a First Class Market Certificate), from Messrs. Cragg, Harrison, and Cragg, Heston.

Commendations were made to Ronald, a golden-bronze decorative variety, from Messrs. Cragg, Harrison, and Cragg; to White Wonder, a white Japanese variety, from Mr. David Ingamells, Covent Garden; to Louis Germ, an ivory-white sport from Sax Export, from Messrs. J. and J. Sax, Nordrecht, Holland; and to Orangeman, a yellow single, from Mr. B. Nash, Cheam.

The leading class was for eight vases of disbudded chrysanthemums, nine blooms in a vase, and here there were two competitors. Messrs. Cragg, Harrison, and Cragg, Merivale Nurseries, Heston, Middlesex, secured the premier award with vases of first-class blooms of Heston Pink, Russet, Mrs. J. Thompson, Godfrey's Crimson, Mrs. F. Judson, Matthew Hodgson, F. Pilon (a bright yellow incurved form), and December Pink; second prize went to Mr. J. Godber, Willington Nurseries, near Bedford, who showed Mrs. J. Thompson, Golden Thompson, Mrs. Judson, and Bronze Thompson in good form.

The best set of three vases of white blooms came from Messrs. Cragg, Harrison, and Cragg, who chose as their varieties Mrs. Judson, Mdlle. Pankoucke, and Mrs. J. Thompson, all finely represented; Mr. J. Godberg second, and Mr. T. Stevenson, gardener to E. G. Mocatta, Esq., third. The class for three vases of blooms, distinct varieties, found Messrs. Cragg, Harrison, and Cragg in the first place, with fine flowers of Heston Pink, Russet, and Yellow Thompson; Mr. J. Simon, gardener to W. W. Mann, Esq., Ravenswood, Bexley,, second; and Mr. J. Godber third.

Mr. Thos. Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, Addlestone, led the way for three vases of singles with delightfully fine blooms of Mrs. Hubert Williams, Kathleen May, and Brightness; Mr. L. E. Lawrence, gardener to Mrs. Roger Gregory, Shoreham, second. Messrs. Cragg, Harrison, and Cragg annexed the first prize for a vase of disbudded singles, winning with the rich crimson Kathleen May. For partially disbudded singles, the same firm held premier position with Godfrey's Perfection; Mr. J. Clayton, Greycot, Addlestone, second; with Cecily Joyce Clayton, a red seedling.

Mr. Thos. Stevenson scored for a vase of a dozen blooms of single varieties, with a finely grown set, which included Kathleen May, Brightness, and Mrs. Hubert Williams; Mr. F. D. Humphries, gardener to F. B. Mildmay, Esq., Shoreham Place, Sevenoaks, second.

The best bloom in the show was a large example of Mrs. Gilbert Drabble, shown by Mr. R. B. Leech, Woodhall Gardens, Dulwich, in a large vase of big blooms associated with fronds of Woodwardia radicans. This vase was one of three large ones boldly filled with big blooms of Mr. Leech, and which made a charming exhibit to which a silver-gilt medal was awarded.

Messrs. Butler Brothers, Bexley Heath, were the only exhibitors of a group of dwarf plants in pots, and they secured the first prize with freely-flowered specimens in small 48's, grown in the usual first-class fashion common to this firm.

The finest individual exhibit, and one to which a gold medal was awarded, was set up by Messrs. Cragg, Harrison, and Cragg, Heston, Middlesex. This firm set up grand bunches of Matthew Hodgson, Manor House Gem, Yellow Princess Victoria, Well's Late Pink; Yellow Mrs. Thompson, Russet, Phœbus, Rosalind, and December Gold, all lovely decorative Japanese varieties; with such fine singles as Kathleen May and Crimson Queen. Four plants of Heston Pink, with some grevilleas, formed a good background for this display of nearly a thousand blooms.

Messrs. W. Wells and Co., Merstham, secured a large silver medal with their stand of the lovely pink Bertha Lacheau; the yellow James Fraser, an elegant new Japanese variety; Wm. Turner, Daily Mail, and Mauve Beauty, besides the singles Marjorie Harris, Mrs. W. Prowting, and Merstham Jewel.

THE ANNUAL DINNER.

There was a very large attendance at the Holborn Restaurant on November 28, when the National Society held its annual dinner, under the chairmanship of the President, Sir Albert Rollit, LL.D. After an excellent dinner the usual loyal toasts were honoured, and then Sir Albert distributed the principal cup and medals won at the Crystal Palace early in November.

The chief toasts, all enthusiastically received, were: "The Donors of Special Prizes," given by Mr. John Green, and responded to charmingly by Mr. J. R. Jackson; "The Exhibitors and Affiliated Societies," given by Mr. R. J. Frogbrook, and responded to by Mr. R. B. Leach; and, of course, "The National Chrysanthemum Society," proposed by the President in an able and humorous speech, and duly responded to by Mr. Thos. Bevan. Sir Albert pointed out that the society had a larger number of guinea members than ever before, and many of these moved in a high state of society; and that the income was larger than usual, and so the society was in a better financial position than for many years past. He made special reference to the value of the Society's Conferences, and to its publications, and to the great success of the society's November show, when 20,000 people passed through the turnstiles at the Crystal Palace.

Sir Albert had to leave somewhat early, and the toast of "The President" and that of "The Press" were honoured after he had left.

Among those present, not already mentioned, we noticed Mr. R. A. Witty, Mr. Prickett, Mr. E. F. Hawes, Mr. D. B. Crane, Mr. D. Ingamells, Mr. R. Ballantine, Mr. Hiehle, Mr. W. Wells, Mr. W. Howe, Mr. Emberson, Mr. Ladds, Mr. Schneider, Mr. G. Hunt, Mr. T. Stevenson, Mr. T. Bevan, Mr. C. H. Curtis, Mr. Cowley, etc.

National Hardy Plant Society.

The annual meeting of this society was held in the Horticultural Club Room, Hotel Windsor, Westminster, on December 9. Mr. J. Bonskell occupied the chair, but the attendance was quite modest. After the minutes had been passed, the annual report was read by the hon. secretary, Mr. A. J. Macselfe, and it covered the work of the society during the year, referring chiefly to the awards made by deputations at various exhibitions throughout the country where hardy flowers were prominently displayed—notably at Taunton, Shrewsbury, York, and Edinburgh. The financial statement, presented by the hon. treasurer, Mr. Robert Morton, showed a total turnover of just under £100, and included £31 expended on the society's "Year Book," and a balance of over £36 to be carried forward to the credit of the society. It was agreed, however, that the treasurer should keep the accounts open until December 31, meanwhile paying one or two outstanding liabilities, and endeavouring to secure some subscriptions still unpaid.

The Hon. Vicary Gibbs was requested to act as President for 1914. Mr. Bonskell was re-elected chairman of Council; Mr. A. J. Macselfe as hon. secretary; and Mr. R. Morton as hon. treasurer. The Council and the Executive Committee were re-elected, as were the Publications and Scientific Committees, with a few additions to fill up vacancies caused by resignation and death.

It was agreed that the society hold its competitive exhibition at the Royal Horticultural Hall, Westminster, on June 4, 1914, and also combine with the Horticultural Committee of the Anglo-American Exposition, at Shepherd's Bush, in 1914, for the purposes of holding an exhibition of and conference on hardy plants at the White City.

Numerous suggestions were made for furthering the purpose of, and increasing the interest in, the society, and most of these will be published in the society's "Annual." It was also agreed that the Executive Committee meet during the greater part of the year, at five p.m. on the first meetings of the Royal Horticultural Society each month.

The Horticultural Club.

The usual monthly dinner of the club was held on Tuesday, December 2, at the Hotel Windsor, Westminster, Sir Harry J. Veitch presiding.

After the dinner, as is customary, a lecture was given, the subject this time being "A Ramble Along the West Coast of Vancouver Island," illustrated by a large number of lantern slides, taken and coloured by the lecturer, Mrs. Julia L. Henshaw, at present on a visit to London from Canada.

About a year ago this lady favoured the club with a description of some of the Canadian flora and fauna, which was so much appreciated that a second lecture was solicited, and now gave, if possible, even greater satisfaction. By means of a map of Canada, thrown upon the screen, she demonstrated the peculiarly favourable position of Vancouver Island as regards vegetation, its position on the extreme South and its entire environment by the Pacific Ocean, imparting mild climatical conditions, not unlike those of our Western Coasts, or even milder still, though

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,

London, E.C.,

who will give the matter immediate attention.

the existence of a range of snow-topped mountains in the centre provided such varied conditions as regards humidity that the rainfall ranged between 28 inches and 100 inches, while their slopes furnished nearly every zone of vegetation from the mild-temperate to the arctic.

The views, both of the coast and the interior, were charming, and the lecturer's own colouring, so well done that they were taken for nature prints, until she explained to the contrary. Grand views of deep and well-wooded villages, leading up to a range of snowy peaks, demonstrated clearly that, as regards picturesque and even grand scenery, Vancouver could well hold its own with many European resorts, Swiss and others, while, as she expressed it, they possessed in addition the subtle lure of the West and of the unknown. The slides depicting the varied flora of the locality were equally well done, peculiarly so indeed, their arrangement and perfect focussing giving a truly stereoscopic effect. One in particular, of Cornus Nuttalli, showed a tree over 60ft. high, and one mass of beautiful flowers hiding the foliage entirely, and this was followed immediately by a slide showing the individual beauty of the flower clusters themselves, and evoked special admiration, as in this country the species can only be developed as a shrub.

The slides followed in rapid succession, and were accompanied by most interesting remarks concerning native customs, adventures en route, peculiarities of habitat, etc., of the plants found at the very varied levels the mountains provided, historical data of the localities visited, and so on, which rendered the lecture one of the most instructive and amusing in the annals of the club.

After some remarks by Sir Harry J. Veitch and Messrs. Cheal, Druery, and others, to which Mrs. Henshaw replied, a most cordial vote of thanks to her was passed with acclamation, and the hope was also expressed that on a future visit to England the club might be favoured with another lecture, as it was Mrs. Henshaw's intention to devote herself still more to the research concerned.

Bournemouth Gardeners' Society.

Mr. Elfrod, of Winton, near Bournemouth, gave a very able and interesting lecture on "Border Carnations" before this society in Tuesday, November 4. Mr. Elford is an expert cultivator; he dealt with the cultivation of border carnations in pots, first, and then as border plants. His remarks were concise and to the point. Mr. Heath, gardener to G. G. Russell, Esq., Glenfallock Gardens, occupied the chair, and led the long discussion which followed the lecture.

In propagation, the lecturer advised the selection of sturdy shoots, the removal of the old soil to a depth of 1in., the use of a gritty compost, and slitting the stem up to the first joint from the insertion of the knife. The soil should never become dry. When well rooted, the young plants should be placed in pots 2½in. wide by 4in. deep. The pots and crocks used must be quite clean and dry. The secondary potting should be done in March; good loam cut and stocked the previous summer, with rotted leaves and a small quantity each of mortar rubble, and bone-meal added, being the compost recommended. Staking must be done when the flower stems become prominent. Referring to carnations grown in the garden borders, Mr. Elford said they rarely had fair treatment. Instead of being planted in good positions, they were often given odd corners and indifferent soil. He advised members to try the plants in rose beds, also in ground previously occupied by sweet peas. The following twelve varieties were named as being good standard sorts, when asked to name a dozen by a member present: Agnes Sorrel, Bob Acres, Old Clove, Duchess of Wellington Elizabeth Schiffner, Glory de Nancy, Linkman, Lord Steyne, Miss Willmott, Trogan, Mandarin, and Sir Galahad.

Smithfield Club.

The annual show at Islington, which opened on Monday, December 8, and continued until Friday, December 12, was, in general aspect, just like the shows of former years, and the seedsmen's stand and exhibits of implements in the galleries were for the most part such as we have seen time after time. The swedes, mangels, and sugar beet shown by the large growers, were of good, all-round quality, and potatoes were forthcoming in quantity, albeit we heard frequent remarks on the meagre crops obtained in many districts. From a commercial point of view, Smithfield Show is an event of great importance, and we are glad to record another successful exhibition of Britsh-grown produce at the Royal Agricultural Hall.

Messrs. Sutton and Sons' extensive stand was made attractive by means of a series of colour photographs, showing many kinds of flowers, vegetables, etc., both growing and in a cut state. Mounted specimens of injurious insects, and preserved examples of black scab in potatoes, with other exhibits of scientific interest, made the stand an object of educational value, and, it may be added, that the vegetables exhibited were of the firm's usual high standard .

Messrs James Carter and Co., Raynes Park, had their seed germinators on view, and there were also excellent tubers of many varieties of potatoes, with Ailsa Craig and Record onions and other vegetables. Messrs. E. Webb and Sons, Wordsley, staged a large variety of potatoes, some of the best sorts being New Provider, New Majestic, Stourbridge Glory, and Arran Chief.

Messrs. John K. King and Sons, Coggeshall, showed the quaintly-named potatoes Mighty Atom, and Rent Payer among other good sorts; and an excellent flat-bulbed onion, named Reading Matchless, was well shown. About sixty varieties of potatoes were exhibited by Messrs. C. Fidler and Son, Reading, a few varieties that stood out conspicuously being Dalhousie, Table Talk, Dreadnought, Dalmeny Hero, and Duchess of Cornwall. Messrs. Harrison and Sons, Leicester, as usual showed some good serviceable onions, beetroot, parsnips, and their round white potato Weight and See, a heavy-cropping second early. Mr. A. Findlay, Auchtermuchty, had fine tubers of the latest introductions among potatoes. One of the principal varieties was Majestic, which last year was shown as an unnamed seedling. It is a handsome potato of good size and shape.

Messrs. Kent and Brydon, Darlington, had Arran Chief potato in good form, other varieties being The Brydon, which yielded 16 tons to the acre this year, and The Darlington, a late variety, which is white-flowered, an unusual characteristic in late potatoes. There were several good exhibits of fruit, the extensive display from King's Acre Nurseries, Hereford, being replete with highly-coloured dessert and culinary apples. Messrs. W. Horne and Son, Lim., Cliffe, Rochester, also showed fruit and young trees, while other firms represented were Messrs. Dickson's, Lim., Chester; Messrs. W. and J. Brown, Stamford; and Messrs. W. Seabrook and Son, Chelmsford.

Tunbridge Wells Gardeners' Association.

The annual dinner of this association was held at the Friendly Societies' Hall, on Tuesday, December 2, when over 60 members sat down to an excellent repast. Mr. E. Charlton was in the chair, and, after the loyal toasts, presented the cups and prizes to those successful at the recent chrysanthemum show. After other toasts had been honoured and speeches made, the rest of the evening was devoted to a musical programme, over twenty local performers voluntarily contributing to the enjoyment of the gathering.

It is possible that the chrysanthemum show of 1914 may be held in the Pump Room, instead of the Great Hall, as a change of site may prove beneficial.

Scottish Horticultural Association.

The monthly meeting of this association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on the 2nd inst. Mr. King, the president, was in the chair, and there was a good attendance.

The meeting was an open one, and devoted to the discussion of various matters connected with horticulture, including size in relation to quality in judging potatoes; the brighter colouring of the foliage of the scarlet or red oaks on the shoots produced from near the base, as compared with that higher up the tree; the covering of vine borders with straw at mid-summer; and the flagging of chrysanthemum blooms on the exhibition table. It was contended on one side that the brighter colour in the oak leaves was for protective purposes; on the other that it was due to better nourishment. It was generally conceded that medium-sized potatoes, with shallow eyes, of good shape, and of good quality, were to be preferred to larger tubers. An insufficient supply of water, due often to their being placed in too small vessels, was given as the most common cause of chrysanthemum flowers flagging; and there was diversity of opinion as to whether vine borders should be covered. A question relating to the best means of utilising the land had to be abandoned owing to lack of time to discuss it.

The exhibits were a collection of single and decorative chrysanthemums, displayed by Messrs. Dobbie and Co., Edinburgh; Chrysanthemums Miss Marion Raven, Margaret Gray, Mensa, Phyllis Bryant, Mrs. R. C. Cowan, and Miss E. L. Cowan, exhibited by Mr. W. G. Pirie, Dalhousie Castle, Midlothian; and spikes of Cymbidium Traceyanum from Mr. D. Halliday, Ascog, Buth. Each of the exhibitors received a Cultural Certificate.

It was intimated that the balance of receipts over expenditure at the Chrysanthemum Show was about £80, and that the drawings from the bazaar in aid of the Horticultural Institution Fund had realised over £800. November 19, 20, and 21 were fixed as the dates of the 1914 exhibition.

Dundee Horticultural Association.

Mr. William Christeson presided at the monthly meeting on December 5, when Mr. J. S. Chisholm again lectured, this time on "The Cultivation of the Apple." In dealing with the subject, the lecturer gave delight to his audience by the scientific and practical manner in which he discussed every detail regarding successful cultivation. His own conviction, "that Scotland might produce more and better fruits if land could be had in suitable localities," was endorsed by all present. Points emphasised in the lecture were the importance of lime, soil of a moderately heavy loam, a slight elevated site, with a south-western aspect, natural or artificial drainage, and the necessity of working on practical and scientific lines in regard to manuring, feeding, pruning, etc., always keeping a good natural balance between branches and roots, encouraging the latter near the surface, and restricting the former by summer pruning. The effect of spraying with approved sprays at various seasons, to ward off attacks of, and destroy insect and fungoid pests, was clearly demonstrated. He said bush trees on the English paradise stock, planted at 8ft. to 10ft. apart, were the most economical, coming quickly into fruit-bearing, and easily managed in regard to spraying and pruning.

After satisfactorily disposing of a few questions from members, the lecturer was cordially thanked.

Mr. James Staward, St. Fort Gardens, set up an exhibit of Begonia Gloire de Lorraine and a well-grown cyclamen. Mr. James Bethel, The Grange Gardens, showed blooms of a yellow sport from Western King chrysanthemum, which he fixed last year.

THE GARDENERS' MAGAZINE

ON AND AFTER JANUARY 3, 1914,
The Gardeners' Magazine
WILL BE PUBLISHED AT
One Penny
INSTEAD OF TWOPENCE

THE NEW SERIES.

SIZE AND STYLE.

Although the price will be reduced, there will be no reduction in the amount or quality of the literary matter provided, or in the number of illustrations.

HORTICULTURAL NEWS.

Reports of Flower Shows, Meetings of Horticultural Societies, and news of current events in the World of Horticulture will be a leading feature.

NOTES OF OBSERVATION AND EXPERIENCE.

A quite new feature will be the regular publication of short notes dealing with the peculiarities of Plants, Flowers, Fruits, and Vegetables, Interesting Experiences, and the results of close personal observation.

THE PROFESSIONAL GARDENER.

First and foremost "The Gardeners' Magazine" caters for Professional Gardeners, and no effort will be spared to provide sound and practical advice and information on the many important matters that claim the attention of the supervisors of large Private or Public Gardens, and the workers in trade establishments.

THE YOUNG MAN.

Special attention will be devoted to the needs, aspirations, and education of Young Professional Gardeners; and those who have risen from the ranks by means of their own study and industry will, in "The Gardeners' Magazine," record their experiences, and contribute Articles on Landscape Gardening, Garden Management, Note Taking, Soil Science, etc., etc.

GARDENS OF BEAUTY.

"The Gardeners' Magazine" already enjoys a high reputation for its descriptive and illustrated accounts of Gardens and of Garden Scenes. The larger establishments will be dealt with, but special attention will be devoted to others which possess unique features and compare favourably in beauty, if not in extent, with those more frequently described.

NEW PLANTS AND FLOWERS.

This feature will be continued and, week by week, comparative and interesting descriptions of novelties will be published, and the important subjects illustrated.

HARDY HERBACEOUS PLANTS.

"The Gardeners' Magazine" will give the fullest possible assistance, by text and illustration, in the preparation and planting of Flower Borders, Colour Schemes, and the General Management of all kinds of Hardy Flowers.

FRUIT CULTURE.

In this department "The Gardeners' Magazine" will find no difficulty in maintaining the foremost position it has so long occupied. The most skilful cultivators and exhibitors have promised to give us their assistance.

ROCK AND WATER GARDENS.

While the more imposing Rock Gardens and Water Gardens will be described and illustrated, a special effort will be made to show that Alpine Flowers and Aquatics may be enjoyed in Gardens of modest dimensions.

THE ADVANCED AMATEUR.

The wide-spreading popularity of horticulture has created a new class of amateur gardeners, who, with professional assistance, find healthful pleasure and recreation in the cultivation of their gardens, often specialising in one or more subjects. For their special benefit, skilled amateurs will contribute to the new series, and illustrations of successful cultivation will be published.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of THE GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Specimens of plants, flowers, and fruits for naming, or opinion, should be sent to the Editor of THE GARDENERS' MAGAZINE, 2, Adelaide Road, Brentford, Middlesex, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notifications of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in THE GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

LILAC SUCKERS.—S. G., Hendon: I am an amateur with a fairly large garden, and so have frequently to employ professional help. The man employed is very intelligent and has a far wider knowledge of plants and gardening than the average jobbing gardener, but I am wondering whether he is correct in wishing to root out all the basal or sucker growths from a lilac. We have a large tree with three main stems, and the flowers were very fine last season. Several sucker growths have appeared round the base of these stems, and, rightly or wrongly, I have not permitted their destruction. The point is, should they remain, or be destroyed?—In the case of fine varieties of lilacs, sucker growths should be removed, and the growth on the main stems should be pruned after flowering, the old flowering stems being cut out, and only sufficient new growths for where there is room, allowed to remain. Liquid manure or a mulching of rich manure should be given immediately after flowering is over.

A HUGE CHRYSANTHEMUM.—R. B., Roydon, very kindly sends us a cutting from a Denver newspaper referring to the huge chrysanthemum, and he writes that the illustration of this enormous plant reached him while he was reading our paragraph on page 916. There is no further information on this subject than we have already given, but our friend wonders whether the illustration could be produced.—We are much obliged to "R.B." for sending us the cutting referred to in his letter, and, though the illustration is quite useless for reproduction, this does not lessen our indebtedness to him for the trouble he has taken.

COMPETITOR'S QUALIFICATION.—Vectis, Newport: I shall be obliged if you will kindly give me your opinion of the following matter. At our chrysanthemum show, of which I enclose a schedule, we have a cottagers' section, and it is in connection with this I am writing. Rule 12 states: "No one will be allowed to enter as a cottager whose rent exceeds £15 a year, or who is a gardener's assistant." Rule 14 reads: "All specimens must be the bona fide property of the exhibitor or his employer, and have been under their cultivation at least two months previous to the show; and must be plants of one year's growth, and single plants in a pot. Each plant must show a clear stem above the pot. All plants must be grown on premises in the occupation of the exhibitor." A young man who exhibited lives at home, and pays his father a nominal sum of about £8 a year for a room and piece of the garden, and here he grows his chrysanthemums. The house and garden are rented at about £30 a year. This young man entered as a cottager, and some of us contend he has no right to compete in the cottagers' section. Unfortunately the committee seems inclined to let the matter slide, although an objection has been lodged against the young man.—We admire the energy and skill of the young man who so successfully grows chrysanthemums in his father's garden, but obviously he is not a cottager. A piece of ground in a large garden is very different to a fenced-in garden of the same size as the piece. We take it the premises on which the chrysanthemums were grown are in the occupation of the father, therefore the plants were not grown "on the premises in the occupation of the exhibitor," and such an exhibitor's claim to be a cottager within the reading and meaning of the society's rules, would not, as we understand it, be upheld in a Court of Law.

POTATO BUTLER'S DEFIANCE.—Our Grimsby correspondent who desired to know something about a potato named Butler's Defiance, will be glad to learn that our note on page 934 has brought an answer from Mr. W. E. Sands, of Hillsborough, Ireland, who has a very wide knowledge of potatoes. He writes: "Noticing the request on p. 934 of THE GARDENERS' MAGAZINE, for information concerning Potato Butler's Defiance, I hasten to say that this variety was introduced in 1912 by Mr. A. J. Butler, of Scotter, near Gainsborough, Lincs., who raised the varieties King George V. and King Edward VII. Butler's Defiance is a splendid potato, a good cropper, fine cooker, and of lovely shape, being a kidney variety with shallow eyes right on the surface. I have grown this potato for the past two seasons." We are obliged to Mr. Sands for his letter.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

M. E. J., Maidstone.—Pittosporum undulatum.

S. J. Bournemouth.—1, Pteris umbrosa; 2, Eranthemum pulchellum; 3, Aglaonema costata.

N. G. A., Alnwick.—1, Lilium nepalense; 2, Gazania latiflora; 3, Gaultheria procumbens; 4, Arearia balearica.

L. C. C., Emsworth.—1, Salvia Betheli; 2, Eupatorium ianthinum; 3, Phyllanthus glaucescens; 4, Cupressus funebris.

J. D., Ryde.—The specimen enclosed was Clematis cirrhosa; no flower of a salvia was sent, though your letter referred to one.

NAMES OF FRUITS.

When sending fruits for naming, will our readers be good enough to send good specimens, as without these it is not possible to accurately determine the varieties. Pack firmly, using light tin or wood boxes, and send not more than six varieties at once. Label each specimen and enclose letter with the fruit, whether a separate notification is sent or not. Address the packages to the Editor, GARDENERS' MAGAZINE, as advised in the notice at the head of "Answers to Correspondents."

G. C., Derby.—1, Blenheim Pippin; 2, a small Gascoyne's Scarlet.

T. C. A., Colchester.—1, Sykehouse Russet; 2, New Hawthornden.

R. H., Wye.—1, Newton Wonder; 2, Lane's Prince Albert; 3, probably Bramley's Seedling, a deformed specimen.

F. K. G., Tunbridge Wells.—1, Claygate Pearmain; 2, Smart's Prince Arthur; 3, King of the Pippins; 4, Kerry Pippin; 5, Fearn's Pippin; 6, Winter Nelis.

FORTHCOMING ENGAGEMENTS.

TUESDAY, December 16.—Royal Horticultural Society; Committees meet at 12 o'clock to consider novelties, but there will be no exhibition.

WEDNESDAY, December 17.—Royal Meteorological Society.

THURSDAY, December 18.—Linnean Society.

CATALOGUES RECEIVED.

VILMORIN-ANDRIEUX AND CO., 4, QUAI DE LA MEGISSERIE, PARIS.—A wonderful catalogue of seeds of hardy trees and shrubs, running to over fifty closely-printed octavo pages. Quite a dictionary of genera and species.

NORMAN DAVIS, FRAMFIELD, SUSSEX.—An autumn catalogue of unfailing interest to all lovers of chrysanthemums and Michaelmas daisies. Mr. Davis is a past master in raising and cultivating varieties of both these useful floral families.

COUGHS, COLDS,
ASTHMA, BRONCHITIS.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Silver-leaf Disease.

The ravages of the disease commonly known as Silver-leaf continue to spread with ever-increasing rapidity, and have now become so widespread as to annually inflict heavy losses upon the owners of fruit gardens and plantations, more especially in districts where plums are largely grown. This disease has long been known to fruit growers in this country from the silvered appearance of the leaves of the trees suffering from an attack. Not, however, until within a quite recent period has its direful effects upon plum trees been fully recognised by practical cultivators, or its cause otherwise than imperfectly understood even by the most advanced of plant pathologists. No farther back than fourteen or fifteen years ago the silvering of the leaves of the plum and some other fruit trees was believed to be chiefly, if not wholly, due to a deficiency of iron in the soil, and the remedy almost invariably recommended was sulphate of iron, applied in the form of a top-dressing, and well watered in. Now it is known to those who have devoted some share of their attention to the study of plant diseases that when a plum tree has leaves of a silvery-grey hue the tree is not suffering from an insufficiency of iron or other mineral essential to its healthy development, but is the victim of an attack by one of the most insidious of the fungi that prey upon fruit trees. One of the scientists to engage in the investigation of the Silver-leaf disease was Professor Percival, of the Reading University, and as the result of his well-directed efforts he was able to show, in a communication to the Linnean Society's Journal in 1902, that the disease was of fungoid origin. He was also successful in proving to demonstration that the fungus causing the disease is Stereum purpureum, which bears its fruits only on the dead wood of a tree killed by the attack. At first Professor Percival's conclusions were received with some doubt, but this has long since passed away, and they are now accepted by all who give attention to the experimental aspects of fruit culture. Mr. Spencer Pickering, whose work as Director of the Woburn Experimental Fruit Farm is well known, was one of the first to put Professor Percival's conclusions to a thorough test, and in the course of his investigations he obtained unquestionable evidence as to their correctness. He, as Professor Percival had done, found that the fungus could be readily studied in the various stages of its life history, and that the disease could be conveyed from an infected tree to one that is perfectly healthy without any difficulty by inoculation. The fungus, when it reaches the fruiting stage, forms flat discs on the surface of the infected branch, and it was simply necessary to take a portion of one of these, not exceeding double the size of a pin's point, and insert it in a small cut on one of the branches, to infect a healthy tree, and cause its untimely death. The

MR. J. R. TOOLEY.

facility with which disease can be conveyed from one tree to another is a point of considerable practical importance, inasmuch as it indicates the necessity of care in pruning, and the avoidance, as far as practicable, of injury to the bark. Careful pruning consists in cutting away dead or dying branches well below the indications of disease, and in avoiding the use of the same knife in pruning diseased and healthy trees without sterilising, previous to commencing to prune the latter. The spores of the Stereum are carried by the wind from one tree to another, and if they can effect a lodgment on an abrasion of the bark or a cut, they soon germinate and penetrate the tissues, through which they spread at a somewhat rapid rate. If, on the other hand, they alight on a branch with perfectly sound bark, the spores fail to germinate, and quickly perish. This fact suggests the desirability of not only preventing injury to the bark, but of covering the larger wounds made in pruning the trees with gas-tar, which at Kew is used with much success in coating wounds caused by the removal of large branches of ornamental trees, for Stereum purpureum is not the only fungus that can obtain access to the tissues of trees by means of cuts and other wounds. Mr. F. T. Brooks, of the Cambridge University, has also devoted much time to the investigation of Silverleaf disease, and in an important contribution to the current issue of the "Journal" of the Board of Agriculture he not only describes the scientific aspects of the disease, but makes special reference to the means by which it may be held in check. He suggests that not only should the infected branches be removed but that they should be cut back below the limit of the discoloured wood. Cases of natural recovery of trees which are slightly diseased are, as both Mr. Brooks and Mr. Spencer Pickering have found in their investigations, not infrequent; but trees that are badly silvered, and beginning to die back, should, in Mr. Brooks's opinion, be destroyed. Such trees should not only be cut down, but they should be removed from the plantation and burned. To allow dead trees to stand in the plantations, or to be piled up on their margins, is a practice by no means unknown; but it should be carefully guarded against, for each tree or pile of trees becomes a centre of infection. Improper grease-banding is regarded by Mr. Brooks as another factor which favours the development of the disease, for where the grease has been placed directly on the tree, or has soaked through the band, the bark frequently becomes torn and decayed, and such tissues offer every facility for Stereum purpureum to obtain ingress to the tree.

Mr. J. R. Tooley.—A native of Boston, in Lincolnshire, Mr. J. R. Tooley comes of a seafaring stock, but the ocean did not appeal to him, and at the early age of thirteen he was apprenticed for six years with Mr. J. Christie, in the Park Nurseries, Boston. After his apprenticeship Mr. Tooley decided to enter private service, and three years later he was at Waddesdon Manor, learning something about orchids under Mr. J. Jacques, but it was at Trent Park, New Barnet, under Mr. H. H. Lees, that Mr. Tooley acquired the taste for exhibiting which has never left him. During the seven years he stayed at this establishment the names of Trent Park and Lees were household words among lovers of chrysanthemums, and the young foreman was entrusted with the staging of many a winning exhibit in

England, Ireland, and Scotland. Mr. Tooley's first charge as head gardener was at Maesgwynne, in Wales, where he got together a very fine collection of rhododendrons, azaleas, and peat-loving plants. On the death of his employer he returned to England, and was engaged by Mr. Hugh Andrews as head gardener at Toddington Manor, in Gloucestershire. Here Mr. Tooley has had scope for the exercise of the splendid abilities he possesses as a gardener. He is a man of small physique, but abundant energy, and nothing comes amiss to him. This season he has added dozens of prize cards to his already big stock. Mr. Tooley is a man of many parts, however, and he grows vegetables that are good enough to win in the big open classes at Shrewsbury, and he is one of the most successful grape growers in the West of England. Those who saw the splendid collection of grapes exhibited at the Bristol Chrysanthemum Show from Toddington, not for competition, will testify to this; and amidst all his success Mr. Tooley is modest and unassuming, keen, and with an ambition that his brought him right into the front line of British gardeners.

A Successful Chrysanthemum Conference. — At Essex Hall, Essex Street, Strand, W.C., there was an audience of upwards of a hundred members and friends on Wednesday, December 10, when the National Chrysanthemum Society held a most successful conference. Mr. Norman Davis dealt with "The Evolution and Development of Outdoor Chrysanthemums," and he was followed by Mr. Thos. Bevan, who gave an especially instructive lecture on "Chrysanthemums for Outdoor Garden Decoration," and made his discourse doubly interesting by the free use of lantern views, showing how he grows his plants at the Marylebone Cemetery, East Finchley, and the manner in which he displays them in beds and borders for the creation of beautiful effects in the autumn. Mr. E. F. Hawes presided. It was evident from the numerous questions asked and the many points raised that the interest in chrysanthemums is as keen as ever, though, perhaps, the enthusiasm has passed on a little from the big blooms to the single varieties, and those grown for market and for outdoor decoration.

Sale of the Covent Garden Estate.—Seldom has a change in proprietorship caused such a sensation as the sale of the famous Covent Garden estate of the Duke of Bedford to Mr. Mallaby-Deeley, M.P. The estate covers about nineteen acres, and includes twenty-six streets, Covent Garden Market, and several of the largest hotels and theatres in London. It was on Tuesday last that notification of the sale became public, and since then many folks have guessed at the number of millions of pounds Mr. Mallaby-Deeley, M.P., is paying for one of the most valuable estates in London. It is in Covent Garden Market that we, as horticulturists, are most interested. Long years ago growers of vegetables and fruits, resident in the villages of Kent, Surrey, and Essex, used to gather to sell their wares in an open square, and so, gradually, the market became a recognised institution. In 1671 market rights were granted by charter to the Earls of Bedford by Charles II., and these have been most carefully preserved, and consequently the Russell family has a monopoly of the sale of fruits, flowers, and vegetables, on the Covent Garden estate. The present market was built in 1831, and additions have been made on several occasions, but even now the accommodation is insufficient for the proper conduct of the enormous business done daily in the market. When the estate passed into the hands of the Dukes of Bedford it was supposed to have had a yearly rental value of £6 6s. 8d. Some years ago it was admitted that tolls, etc., brought in £17,000 a year, and in later times the income from the market alone has risen to £25,000 a year. Covent Garden is generally supposed to be a corruption of Convent Garden, and in early times the property belonged to the Church, and part of it was used as a garden and burial ground by the monks. History shows that the Dukes of Bedford obtained grants of land from the monks of Westminster during the reign of Edward VI., the grants including Sevenacres, which evidently contained Covent Garden and Long Acre. The purchaser of the estate, Mr. Mallaby-Deeley, is member of Parliament for the Harrow division, and has been prominent in several large purchases of land in London; but the present deal is far and away his largest, and, indeed, the largest private purchase of land on record.

Public Bowling Greens at Glasgow.—The Glasgow Parks Department has just issued a schedule showing that the twenty-eight public bowling greens, in nine parks, have cost £15,414 13s. 11d. for formation and equipment. Of this amount the sum of £14,255 18s. 9d. has been met out of Parks Assessments, and the idea is to clear off the whole amount within five years from its being incurred, therefore we find a capital debt remains on only thirteen of the greens. The total revenue from the greens since the first were opened in 1903, up to May 31, 1913, was £12,515 18s. 2d., this sum including over £400 from the hire of rubber shoes. Against this has to be set an expenditure of £11,215 15s. 5d. During the season just ended there have been no fewer than 278,472 players on the twenty-eight greens, and the revenue therefrom amounted to £2,149 1s. 8d.; in May there were 24,620 players; in June, 68,620; in July, 88,392; in August, 64,932; in September, 30,868; and in October, 4,040.

National Diploma in Horticulture.—Readers will remember that in our issue of August 30 we published full particulars of a scheme for the National Diploma in Horticulture, to be awarded by the Royal Horticultural Society under a scheme approved by the Board of Agriculture and Fisheries. These particulars, together with the syllabus of the examination to be held in June next (exact date to be subsequently advertised), are now obtainable in pamphlet form on application to the Secretary, R.H.S. Offices, Vincent Square, Westminster. The preamble states: "It has long been felt desirable in horticultural circles that some diploma should be available for professional gardeners, the holding of which would be an indication of real professional ability. In 1912 the Council of the R.H.S. accordingly approached the Board of Agriculture on the subject, with the result that the approval of the Board was given to the proposal, and authority from his Majesty's Government was given for the diploma to carry the title "National." The examinations will, as far as possible, be held in the latter part of June of each year. Among those for whose benefit the diploma is established are the following: Florists, fruit growers, gardeners, horticultural inspectors, horticultural instructors, landscape gardeners, market gardeners, nurserymen, public park gardeners, and seedsmen. Horticulture is defined as follows: "Horticulture is a definite craft of itself, and not a department of agriculture. Horticulture, as differentiated from agriculture, includes the more intensive cultivation (as usually practised in gardens) of fruit, vegetables, flowers, shrubs, and ornamental trees."

The Gardeners' Magazine for 1914.—The announcement which appeared in our advertisement pages on December 13 to the effect that the GARDENERS' MAGAZINE would be issued at one penny per week on and after January 3, 1914, instead of twopence, has brought us shoals of congratulatory letters. Under the new regime the high quality of our illustrations will be maintained and their number increased, and nothing will be left undone to make the "G.M." increasingly instructive and interesting. We shall continue to cater for the professional gardener, but at the same time pay more attention to the needs of high-class amateur gardeners, and to the young men who are striving to rise in the world of horticulture. Famous contributors to these pages have promised to give us the results of their experience and skill, and numerous new writers, having a practical acquaintance with all that is newest in the science and practice of horticulture, will place their services at the disposal of our readers. We do not wish to labour these points now, because from time to time we shall announce special features. For the present we confidently appeal to our subscribers to show their appreciation of our intention to publish the GARDENERS' MAGAZINE at 1d. by telling all their gardening friends of this great event in our history—a history covering more than eighty years.

Lawes and Gilbert Centenary Fund.—Dr. E. J. Russell reminds us of the movement on foot to celebrate the centenary of the birth of Lawes and Gilbert by the erection at Rothamsted of a commemoration laboratory, at a cost of £12,000. The movement has been so far successful that only the sum of £2,500 remains to be obtained to complete the voluntary contribution of £6,000. The committees are therefore making a special effort to gather this in as early as possible. It rarely happens that so large an amount as £12,000 (£6,000 will be forthcoming as a grant if the other £6,000 is raised voluntarily) can be secured for scientific agriculture for so relatively small a sum as £2,500.

The Chief Attractions at Kew at present include a fine plant of Luculia gratissima, bearing numerous trusses of its sweetly-scented flowers, in the Temperate House; several Javanese rhododendrons are also flowering in the same house, and R. Diadem is especially bright. Some large specimens of cycads coning at the south end of the Palm House are interesting, and the bananas fruiting in the same structure attract much attention. The orchid houses are still very bright with cypripediums in flower, hybrids, of course, being in the majority; a few of the best are C. Maudiæ, C. gigas, C. Manchunian, and C. St. Alban, the latter of fine shape and colour. Many varieties of C. insigne are in bloom, and C. i. Harefield Hall is one of the best. Besides these orchids, there are Vanda suavis and V. s. Veitchi making a good display in the warm division, with a fine batch of Calanthe Bryan, and a few plants of the popular C. Veitchi. No. 4 house (the conservatory), which is always attractive, is very gay just now with chrysanthemums, and a batch of the hybrid Begonia Optima is producing a pleasing effect; while some epacris lend their grace

and beauty to the scene, mixed with winter-flowering heaths. Even out of doors there is much of interest, including the completion of the alterations in the Rock Garden; while the Witch Hazel is flowering, and numerous groups of the hybrid heath (Erica hybrida) are to be found in various parts of the grounds.

Climbing Plants at Nuneham Park, the residence of the Right Hon. Lewis Harcourt, M.P., are a fine feature, as has been shown in these pages during the year now closing, and we refer again to them because Mr. C. E. Munday, the head gardener, delighted the members of the Oxford Gardeners' Association, a few days ago, with a lecture entitled "Creepers, and Rock and Water Plants." Needless to say, Mr. Munday had a wide experience to draw from, and the gardens at Nuneham Park provided him with ample material for a long series of excellent lantern slides wherewith to illustrate his lecture.

Royal Trees at Chatsworth.—During their stay at Chatsworth their Majesties, planted thrifty young specimens of the Cedar of Lebanon to commemorate their visit. Chatsworth already possessed three royal trees—a goodly oak planted by Queen Victoria in 1832, when she was a princess; a Spanish chestnut, planted at the same time by the Duchess of Kent; and a sycamore, planted in 1843 by the Prince Consort. All these royal trees are in excellent health.

Gardener Killed by Falling Tree Limb.—A few days ago, while superintending the lopping of trees in the grounds of St. Michael's Vicarage, Grove Park, Chiswick, a gardener, aged seventy years, was warning passers-by of the possible danger of falling branches, when, it appears, a large branch fell upon him. He was rendered unconscious, and died shortly after his admission to the Chiswick Hospital. The deceased man's name was Mr. Harry Gardiner.

A Check to Fraudulent Exhibiting.—At the Stowmarket County Court a case was brought recently before his Honour Judge Eardley-Wilmot, by the Secretary of the Needham Market Horticultural Society, in which the Committee of the Society sought to recover prizes alleged to have been won with produce not grown by the exhibitor. It was stated the rules of the Society laid it down that all produce shown must be the property of and grown by the exhibitors. Evidence given in support of the Society went to show that the exhibitor in question had not grown the produce wherewith he won prizes in September. His Honour gave judgment for the Society, and ordered the prize in kind to be returned within a few days, and the prize money by instalments, with costs.

Cornish Wallflowers in the Market.—Although it is not at all unusual to find wallflowers in bloom in the late autumn during a mild and open season, it is unusual to find these fragrant flowers sent in some quantity to Covent Garden Market in December, as they have been lately from Cornwall.

Holly Berries are fairly abundant this year, though in some seasons the bright red fruits have been more numerous than now. However, there will be plenty of colour to go with the rich green leaves when decorations begin for the Christmas festivities.

NEW PLANTS AND FLOWERS

CATTLEYA PERCIVALIANA ALBA LADY HOLFORD.

This is a wondrously chaste and beautiful orchid; indeed, one of the loveliest plants seen for a long time. The specimen exhibited carried four flowers, each about five inches across, with sepals and petals of the purest whiteness, and a large lip that is white at the slightly-frilled apex, but rich orange-yellow at the base and in the throat, this bright colouring serving to throw up finely the clearness of the white in the rest of the flower. F.C.C., R.H.S., December 16. Lieut.-Colonel Sir G. Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury.

CYPRIPEDIUM BOURTONENSIS.

A very bold and stately hybrid obtained by crossing Cypripedium insigne Harefield Hall with C. Blanche Moore. Though unusually large, the flower is of fine form, the rounded dorsal sepal being 3¼ inches wide, with a green base, spotted with dull purple, and a broad white apex. The petals and the lip are light green with a little soft purple-brown shading. The lower sepal is as large as the dorsal segment, pale green and white, with a few purple-brown spots. One of the largest cypripediums known. A.M., R.H.S., December 16. Mr. G. F. Moore, Chardwar, Bourton-on-the-Water.

CYPRIPEDIUM CHARLESIANUM VAR. SMARAGDINUM.

Two yellow cypripediums have been combined in this hybrid, its parents being C. Sallieri Hyeanum and C. Leeanum aureum; so it will be readily understood that the newcomer is bright greenish-yellow, with a wide border of white at the apex of the rounded dorsal sepal. The flowers are bold,

CATTLEYA PERCIVALIANA ALBA LADY HOLFORD.

An exquisitely beautiful Cattleya with white flowers and orange-yellow colouring on the lip. F.C.C., R.H.S., December 16. Lieut.-Colonel Sir George Holford, Westonbirt, Tetbury.

large, and substantial, and they shine as though polished. A.M., R.H.S., December 16. F. J. Hanbury, Esq., F.L.S., Brockhurst, East Grinstead.

ODONTOGLOSSUM CLEOPATRA ROSEFIELD VAR.

Though not quite of the best shape, as judged from a florist's point of view, this is a splendid hybrid. The bold sepals and petals are deep Venetian red, with an iron-red tinge, a few very faint markings of pale-yellow and white tips. The lip has a deep rose-red base, and a large clear white apex, carrying a few red spots. The flowers have a breadth of 3¾ inches, without spreading. A.M., R.H.S., December 16. De Barri Crawshay, Esq. (gardener, Mr. Stables), Rosefield, Sevenoaks.

ODONTONIA LANGOWOYI.

This is a distinct and striking hybrid between Odontoglossum Uro-Skinneri and Miltonia Schroderianum. The flowers are of modest size, carried on a stiff and rather upright spike, and they are somewhat starry. Sepals and petals are deep red-brown, with darker and indistinct spotting. The lip has a wide white apex, a rose-red base, and a few rose-red spots on the white part. A.M., R.H.S., December 16. Messrs. Charlesworth and Co., Haywards Heath.

CARNATION PHILADELPHIA.

Another fine addition to the growing list of good perpetual carnations. The flowers are large, shapely, and of a bright rose-pink shade. Stem and calyx are both excellent, but we could not detect any fragrance in the blooms exhibited. A.M., R.H.S., December 16. Messrs. W. Wells and Co., Merstham.

CATASETUM MICROGLOSSUM.

An interesting species, discovered by Mr. W. Fox, growing on a dead stump near an Indian house on the River Igaraparana, a tributary of the Putumayo river in Peru. The species was presented to the Kew collection, and, placed in a tropical house, it has grown satisfactorily under the conditions suitable for other members of the genus. The flowers are borne in gracefully arching racemes, and are dull purple, a colour that is not particularly attractive. It is described as being rather closely allied to Catasetum barbatum, but differing from it and other members of the same group in having a greatly abbreviated and saccate lip, with, as a consequence, the aggregation of the appendages in a dense mass. Bot. Mag., t. 8,514.

IRIS MELLITA.

A hadsome iris, which has been presented to the Kew collection by the Hon. N. C. Rothschild, who states that it was obtained, in the first instance, from Messina, is Cilicia. It is pointed out that, "in referring to this Iris Mellita, it will be observed that Dr. Stapf applies the name, first employed by Professor Janka to a plant from Thrace, in such a way as to include the iris from Asia Minor, described by Mr. Baker as I. rubro-marginata, and at the same time yet another plant which, fourteen years ago, was introduced by the late Mr. Max Leichtlin under the name I. Straussi. In connection with the expression of this more comprehensive view, it may be remarked that Professor Velenovsky, whose local knowledge is so exhaustive, admits that I. rubra-marginata Baker and I. Mellita Janka are identical, and Mr. Dykes, in his recent authoritative review of the genus, does the same thing." It is further stated that "the plant figured is, then, a rubra-marginata, without any trace of the purple edging." The growth is dwarf, and the comparatively large flowers are lurid purple or yellow, veined and blotched with red. Bot. Mag., t. 8,515.

UTRICULARIA LONGIFOLIA.

A well-known and attractive bladder wort which has been in cultivation in this country between thirty and forty years, and has been grown with remarkable success in the Cambridge Botanic Garden. The species is a native of Brazil, and was first discovered by Professor G. Gardner, who found it growing in moist localities on Mount Pedra Bonita, near Tejuco, in the State of Minas Geraës. The leaves are long, slender, and remarkable for their elasticity, and the flowers are of a rich rose colour. Bot. Mag., t. 8,516.

SELECT GRAPES FOR PRESENT PLANTING.

Referring to Mr. E. Molyneux's article on the above topic on page 940, I am not out to criticise, but I should like to know why he did not include Golden Queen in his list of white varieties? I quite agree with all he says about Foster's Seedling and Buckland Sweetwater as early grapes, and, as everyone knows, Muscat of Alexandria is unsurpassed; but in my opinion Golden Queen is a valuable late grape, possessing a crisp and agreeable flavour, and it will hang for a long time. Mr. Molyneux says, in respect of Muscat of Alexandria, that it is rarely a success in a mixed collection. Just so, and this is where Golden Queen scores, for I have recollections of splendid examples of the grape grown twenty-five years ago in company with Lady Downe's and Alicante. The grapes I refer to were highly appreciated for dessert, and bunches from the vines won more than one prize in good competition.

My point is that there are many small establishments where late grapes are wanted, but there is not enough accommodation to enable a whole house to be devoted to Muscat of Alexandria. It is therefore grown in company with Lady Downe's and Alicante, and not often with great success. Still, it can hardly be left out, and, being used first, there are no white grapes when it is over. By including Golden Queen, however, there is a white grape of far better flavour than some black varieties grown to succeed the Muscats, and I have had them, with golden-yellow berries, keeping late with Lady Downe's, after being cut from the vines. Therefore, I wonder why our friend Mr. Molyneux will have none of Golden Queen when he mentions such coarse varieties as Gros Colmar and Gros Maroc, though I am glad to see he does not recommend them. The latter are hardly worth mention, but Golden Queen is worth growing.

G. H. H.

PROTECTION FOR HORTICULTURAL NOVELTIES

The Editor of THE GARDENERS' MAGAZINE is undoubtedly doing a great service to horticulture by allowing correspondence upon this most important subject to continue. If the raiser of new and improved varieties of plants is not safeguarded in some way his business will cease to be a lucrative one, and horticulture, to a large extent, will stand still, for, no matter how interested we may be in our pet subject, few of us are philanthropists. The whole matter is a difficult one, but something in the way of a patent right is necessary.

In carnation growing we calculate that the average is one good novelty in every 5,000 seedlings, but even if we have this number of seedlings, we are not sure of obtaining one of real value, so the expense and uncertainty of it all can be imagined, particularly so when we consider that, after obtaining a seedling of worth, we have to grow it for three or four years to work up sufficient stock and test its qualities. It is necessary to have from 10,000 to 15,000 plants of a sterling novelty the year you send it out, both for exhibition and propagation purposes, so there is some risk. It may develop disease at the last moment. It may not be popular, or some one else may send out a better or similar variety the year previously.

But the lot of the rose and chrysanthemum specialist is worse, because it is practically easy to market carnation blooms without risk of the variety being stolen, but not so with roses and chrysanthemums.

Another great advantage of protecting the raiser of new plants, beyond allowing him to get a fair and just reward for his labours, is that it would protect a man against himself. Anyone selling choice varieties of plants cheaper than the raiser is usually selling over-propagated, weakened stock which may condemn the plant.

MONTAGU C. ALLWOOD.

Hayward's Heath.

Regarding the question of "Protection for Horticultural Novelties," personally I do not think correspondence upon this subject will do much good, for, as we know full well, many of the raisers of sterling novelties do not care to have their names disclosed, and so we do not get the right class of people to take this matter up.

The two writers in THE GARDENERS' MAGAZINE of December 13 are certainly a little green on the subject or they would not write in quite the same strain as they do. The suggestion from "R." is out of the question, because, even if the trade signed an agreement not to reduce prices for a certain period, there are, alas, dozens of so-called amateurs who buy novelties, propagate them all through the season, and sell the plants. Your correspondents certainly have not taken the trouble to read advertisements wherein novelties are offered at low prices within twelve months of their introduction.

Merstham. W. WELLS, JUN.

NERINES.

It is with very great pleasure I find several firms are now seriously taking up the cultivation of the most interesting family of nerines, and I am sure anyone possessing a greenhouse will be well repaid for the little care and attention they give to nerines by the lovely heads of very pleasing flowers which most varieties carry in a free manner, and at a season of the year when greenhouses and conservatories are none too gay.

Unfortunately, with nerines, as with many other plants that are not now in the front rank of popularity, naming and descriptions have become lax, and it is for this reason that I am writing. Although very much interested in the article on "Nerines" written by Mr. Herbert Chapman, which appeared in THE GARDENERS' MAGAZINE of November 29, page 901, I certainly think that portions of it may cause trouble. Mr. Chapman writes: "The first of the species to open, and perhaps the handsomest of all, is N. Fothergilli." Well, I think the gentleman who buys N. Fothergilli may be annoyed to find that his neighbour has N. Fothergilli major in bloom a month or six weeks before him, and also that this variety bears much larger and brighter umbels of flower; the two plants will not stand comparison for a moment.

Again, Mr. Chapman writes: "N. sarniensis (or N. Corusca) comes a little later, bearing heads of orange-scarlet." This statement is very misleading, for, in the first place, N. sarniensis is totally distinct from N. corusca; the latter is orange-scarlet, while N. sarniensis is rosy-carmine. Further, if these two were compared with N. Fothergilli, which Mr. Chapman uses for comparison as regards time of flowering, N. sarniensis and N. corusca would be well over when N. Fothergilli came in—and N. sarniensis is the earlier of the two.

Another point I cannot accept is that N. flexuosa alba should ever be thought a "white form of crispa," as the two are about as wide apart in every sense as are any two nerines. N. crispa has rush-like foliage, and very thin and narrow petals; whilst N. flexuosa alba is probably the nearest variety we have to an evergreen, and is the parent of varieties now being used to obtain an evergreen section.

In conclusion, I would say that my sole reason for writing thus is that, having been interested in nerines for a great number of years, and having handled them in large quantities, I do not want anyone to write me to the effect that our stocks are wrong because they do not agree with Mr. Chapman's descriptions.

SARNIA.

LAELIA ANCEPS.

Where choice orchid flowers are in demand during early winter there is nothing that exactly takes the place of Lælia anceps and its varieties, as the long flower spikes render them suitable to any kind of floral decoration. A representative collection of the varietal forms of this species show great diversity of colouring, from the pure white L. anceps alba to the intense colouring of L. a. Chroderæ. All are beautiful, and worthy of cultivation.

The earliest flowers are now unfolding, and as the coloured varieties are the first to bloom the season extends over a considerable period. The white-flowered varieties, which flower later, include some of the most lovely flowers imaginable. In some cases these white L. anceps do not flower satisfactorily. This is attributable, perhaps, to improper treatment, such as growing the plants in too shady quarters during the summer months.

These Mexican lælias delight in an abundance of light, fresh air at all times, and, when in full growth, a large supply of water at the roots and in the atmosphere. They are sometimes grown on blocks and in baskets, but I prefer the ordinary half-pots or orchid pans as receptacles. No plant that it is possible to grow in a pan should be grown on a block. A healthy batch of L. anceps should carry green, sturdy leaves, as firm as leather. All the varieties of L. anceps succeed in an intermediate temperature, and where a house can be set apart for them their cultivation is simplified. It should be remembered that they flower most freely when allowed to become large specimens, and when cut up into small plants they are scarcely worth house-room.

In the numerous forms of L. anceps the differences are so slight that an ordinary observer can hardly find them. It is not necessary to give a detailed list of varieties, and it will suffice to state that L. anceps Chamberlainiana is the largest and best dark variety, and L. anceps Schroderiana the largest and best white variety. As previously remarked, all are desirable, but the employer's taste must be the rule as to which shall be grown. Perhaps, for the production of large quantities of flowers, the typical L. anceps is the best, as it blooms more freely than the larger and scarcer varieties.

While the plants are developing their flowers they must have water whenever the compost becomes dry, and when in bloom the atmosphere should be kept dry to prevent "spotting." After the flowers have faded only sufficient water should be given to keep the leaves and bulbs plump and healthy. A very dry condition at the roots at this season causes the leaves to turn yellow, and it is with the greatest difficulty they are brought back to a healthy state. It also causes the loss of valuable roots, but the other extreme (overwatering) brings about the same trouble.

When new roots are seen to be pushing from the rhizome of the last-made pseudo-bulb any necessary repotting should be done. After repotting water must be applied with extreme caution, only sufficient being given to keep the plant plump until the new roots have entered freely into the fresh material. The best compost ever put together is easily ruined by an excess of water at this stage. Any compost in which cattleyas succeed will suit L. anceps to perfection; the one I use is made up of equal parts of osmunda, peat, and polypodium fibres, with a small quantity of broken leaves and sphagnum moss, all well mixed together. To prevent this becoming sour all the small earthy particles should be removed, and the whole placed firmly in the receptacles.

When remaking specimen plants as many of the leads should be turned towards the centre of the receptacle as possible, and it is not advisable to leave more than three bulbs behind each leading growth. These back bulbs, having no active roots of their own, obtain their sustenance from the front portion.

During its season of growth the treatment of L. anceps is summed up as follows: warm days and cool nights, with a supply of fresh air at all times. As regards varieties, any orchid dealer's catalogue will give a list of them. J. T. BARKER.

CHRYSANTHEMUM MAUD LOUSADA.

Few of the new chrysanthemums which have appeared this season can compare with Maud Lousada in grace and beauty. It is in no sense a small flower, however, but up to full exhibition standard as regards size, and its long florets curl loosely and droop in a most charming manner, so that a well-developed bloom has great depth as well as breadth. The colour is silvery-mauve, with a paler reverse, and the softness of the shade cannot fail to please lovers of chrysanthemums, while it will also prove of great value to exhibitors in the arrangement of their blooms on boards or in stands. The variety was exhibited before the National Chrysanthemum Society on November 17, by Messrs. H. J. Jones, Lim., Ryecroft Nurseries, Lewisham, and on that occasion was granted a First Class Certificate.

CHRYSANTHEMUM MAUD LOUSADA.

A new, silvery-mauve Japanese variety. F.C.C., N.C.S., November 17. Messrs. H. J. Jones, Lim., Ryecroft, Lewisham.

PREPARING FOR WINTRY WEATHER.

The weather continues mild, and as yet there is no appearance of severe frost, but a change may soon come, and it is therefore a good plan to make preparations accordingly, or serious damage may be done. I remember, in 1879, the weather was very mild until the latter part of November, when severe frost set in and continued for several weeks. Many were not prepared for such a long spell, and, consequently, suffered. Sometimes we have quite mild weather until the turn of the year, and then cold piercing winds, with sharp frosts, prevail for several weeks in succession.

We have now a host of shrubs from the shrubs will often ward off the cold winds, and thus save the plants from harm.

For subjects growing against fences and low walls there should be no difficulty in providing protection. Here, wooden frames with a thatch of ling or straw will be found serviceable; these are very portable, and may be used for other purposes. The ling or wild heather grows in many parts of the country, and is readily procurable. Such coverings could be made ready when the weather is unfavourable for outside work.

Not only do shrubs suffer from the severe

STROBILANTHES GOSSYPINUS.

An attractive plant, worthy of consideration for its white, woolly foliage.

various parts of the world, and these will usually withstand the frost of an ordinary winter unprotected, but should weather of unusual severity visit us, and find us unprepared, many of these choice plants will, in all probability, suffer, particularly those newly planted, for where the soil has been moved quite recently the frost usually penetrates to a greater depth, and for this reason the ground around the roots should be mulched, and if this mulching is brought up round the stems it will protect them likewise. It often happens that frost does less damage than the cold penetrating winds that accompany it, and older plants suffer more than young ones as they are not so readily protected. Where there is a collection of choice shrubs special precautions should be taken for their protection.

In many districts the common bracken grows most luxuriantly, and where it can be readily procured there is no warmer material, or one more readily applied. Branches of spruce placed over and among frosts, but in some places herbaceous plants do so likewise. Where the soil is heavy and of a very retentive nature the crowns of tender plants should be covered with some light material, such as coal ashes, leaf-soil, or powdered moss litter. It is not often the frost penetrates light peaty soil to any considerable depth, therefore plants suffer much less when growing in material of that kind.

Vegetables, too, have to be considered. It is always advisable to have sufficient, turnips, Jerusalem artichokes, carrots, parsnips, and the like, in the store-room, in case severe weather should set in. We all know that such roots are sweeter when lifted from the ground just previous to use, but when sharp frost and deep snow prevail it is a difficult task to lift them. Parsley and other herbs should also be protected in readiness for use. There should always be a good supply of the former in a cold frame, where it may be gathered at any time. The early broccoli must also receive attention, especially those that are turning in. These should be lifted and laid in by their roots in a sheltered place, with their hearts facing the north; a covering of mats can then be thrown over them in case of severe frost, and litter of some kind may be used in very severe weather. In most establishments these winter broccoli are highly prized, and where there are not sufficient pits for their protection much trouble is often experienced in keeping up a supply. It is always advisable to have a supply of seakale roots in readiness for forcing. These should be lifted and laid in where they can be covered with litter.

Chicory and endive should also receive attention. Where the soil is light, and the situation a dry one, the latter will usually withstand the winter in the open, but in some places it is necessary to lift the plants and transfer them to a cold frame, peach house, or other structure.

H. C. PRINSEP.

THE HORSE CHESTNUTS.

(Concluded from page 943.)

Æ. turbinata.

This species is a native of Japan, attaining in that country a height of 100ft. In growth and foliage the small trees in this country show a resemblance to the Common Horse Chestnut, though the panicles of flowers are not so long, and the fruits are smooth. The flowers are creamy white. A tree, probably the first in this country, flowered in Messrs. Jas. Veitch and Sons' Coombe Wood Nursery in 1891. Even when leafless the clean straight branches of the young trees, and the brown bark, give the Japanese Chestnut a distinct and attractive appearance.

Æ. Wilsoni.

This new species was introduced by Mr. E. H. Wilson, in 1908, from Central China. He collected seeds in Western Hupeh and Szechuen, which were raised in the Arnold Arboretum, and a plant sent from there by Professor Sargeant is now in cultivation at Kew. As far as can be judged in a young state the leaflets are longer than those of Æ. chinensis, and in this respect they resemble Æ. indica, but, having a more southern distribution, it may not prove quite so hardy as Æ. chinensis.

Small trees of the following chestnuts are in cultivation at Kew: Æ. Buckleyi, Æ. Busi, Æ. Lyoni, Æ. Sanguinea, and Æ. Whitleyi. So far, their growth and characters suggest they are hybrids, probably between Æ. Pavia and Æ. flava. One or two show signs of proving useful small trees with red, or red and yellow, flowers, but it is too early yet to judge of their merits.

A. OSBORN.

STROBILANTHES GOSSYPINUS.

This is a striking and attractive bush when in full bloom, with its showy, white, woolly leaves. The flowers, borne in large heads, are pale blue or mauve, and very elegant. As with many other species of strobilanthes, S. gossypinus blossoms only once in a number of years, usually about seven years, i.e., when raised from seeds, as in a state of nature. The plant is, however, well worth growing in an English greenhouse or temperate house on account of its effective foliage. It is a native of Assam, being found at 3,000 feet to 6,000 feet elevation. In Ceylon it thrives best at altitudes of 4,000 to 5,000 feet.

H. F. MACMILLAN.

Peradeniya, Ceylon.

THE COTONEASTERS.

(Concluded from page 922.)

C. humifera is a scandent-habited plant from Hupeh. The trailing branches grow with considerable rapidity, quickly covering a wide area. The evergreen leaves are oval in shape, dark green, with a silvery reverse, and up to three-quarters of an inch in length. Its white flowers are succeeded by red fruits. There is no easier kind to increase, as the branches root readily without being detached from the plant.

C. integerrima, a native of the mountains of Europe, is said to have occurred in a wild state in North Wales at one time, notably on Great Orme's Head, but always rare. The deciduous, broadly-ovate leaves are from half an inch to two inches long, and up to one and a-quarter inches wide. The flowers are not showy, and the dark red fruits are less conspicuous than those of many species. It is sometimes called C. vulgaris.

C. laxiflora is a deciduous species from Siberia, of upright habit, with ovate leaves one to one and a-half inches long, which are intensely hairy on the under surface, and axillary clusters of small flowers, which are followed by dark purple, or almost black, fruits.

C. microphylla is, perhaps, one of the best-known of the dwarfer kinds. A native of the Himalaya, it is recognised by its compact growth and more or less prostrate branches. Planted in the open it grows to a height of one and a-half feet or so, but planted against a wall it attains a height of twelve or fifteen feet. The tiny, dark green leaves, white flowers, and red fruits are very attractive. With it may be included the Himalayan C thymifolia, as the two plants are very similar in many respects.

C. nutiflora may be recognised by its long, slender, drooping branches, clothed with ovate or rounded leaves, up to two inches long and one and a-half inches wide, by its clusters of white flowers and rather large red fruits. It is seen at its best after it has formed a definite trunk.

C. nummularia, a deciduous shrub, with rounded leaves, small, white, pink-tinged flowers, and red fruits, is sometimes planted, but is less generally useful than many other kinds.

C. pannosa, a Chinese species, was introduced from Yunnan about twenty-five years ago. Forming a tall, wide-spreading bush, it produces small, ovate or oblong leaves, often less than one and a-quarter inches long, pale green above and grey beneath, small-flowered, and a profusion of red fruits.

C. rotundifolia is one of the most satisfactory of all kinds for general cultivation. Attaining a height of four feet, it is well branched, bears small, dark green, box-like leaves, and a profusion of bright red berries, which often hang throughout winter until the end of March. For some reason birds appear less fond of the berries of this than of any other kind, and only take them when other food is scarce. The species is a native of the Himalaya.

C. Simonsi.—This is a well-known Himalayan species, easily recognised by its stiff, upright habit and profusion of orange-scarlet berries, which are larger than those of most kinds. It is a particularly useful kind for shrubbery planting.

C. tomentosa is an alpine species of little decorative merit.

W. DALLIMORE.

Kew.

ERINACEA PUNGENS.

This beautiful little plant is by no means a new one, as it was in cultivation in this country as far back as 1759; and yet it is still rare in our gardens of to-day. This rarity is partly due to the idea that it is not perfectly hardy in some of the colder parts of the country, but if it is planted at the foot of a warm south wall, or in a sheltered sunny nook in the rock garden, it may be grown quite successfully, and become an object of great charm.

It forms a dense, spiny, almost leafless little bush, producing flowers during April and May, which are arranged in clusters of five to eight, and of a bluish-purple colour. It is closely allied to the anthyllis, being at one time included under that genus, the flowers being very similar, and the chief difference appearing in the habit.

Seeds are produced very sparingly, even in its native country, and this is undoubtedly the chief reason why Erinacea pungens is somewhat scarce. Such seeds should be sown as soon as ripe. If cuttings of young shoots are put in sandy soil, and placed under a handlight, it is possible to secure a few plants, but a better method than this is layering.

The illustration shows an exceptionally good specimen in the Botanic Gardens, Cambridge, measuring 1ft. high, and 27in. in diameter. E. pungens is a native of Spain, and was first discovered by Clusius, who may well have exultingly termed it "A plant undoubtedly new, and full of beauty." It is extremely pretty when in bloom, and therefore deserves to be more widely known and cultivated.

F. G. PRESTON.

ERINACEA PUNGENS.

A close-growing, bushy plant, from Spain; flowers bluish-purple, in clusters.

THE JAPANESE WINDFLOWER.

To Japan, that land of blossom, we are under a heavy obligation. Its flowering trees and shrubs are the glory of the garden in spring; a number of alpines of great beauty come from thence, and Japan gives us in Anemone japonica a plant of incomparable loveliness wherewith to grace our gardens in autumn. This remark applies most literally to the white form, for although the type was known to gardens as far back as 1844, it was some years later before the white variety originated as a sport, while at present probably quite a dozen or more forms have been given distinctive names.

The Japanese Windflower is a familiar subject. The leaves spring in whorls from the woody rootstock, and are ternate or triangular in outline, the lobes being unequal and the segments toothed. Above these, often to the height of three feet or four feet, rise the stiff, wiry stems that invariably carry a whorl of small leaves, which form a common centre, from whence spring the footstalks that carry the flowers. These latter are of good size, frequently three inches across, with the floral segments spread out. Their substance is wax-like and lustrous, and the cluster of anthers in the centre is like a boss of gold.

The rootstock of Anemone japonica spreads underground in a most insidious manner. As illustrating its capacity for increase, I came upon an old garden in Surrey this year where at least twenty yards of a border had become overrun from what was originally but two clumps. Any bit of root having a crown will grow, but it requires some years to establish itself and disclose its fullest beauty.

The Japanese anemone is a subject to conjure with in any scheme of garden decoration where a late display is wanted. I like to have it well in front in border planting, for it imparts that boldness and dignity that we commonly associate with the lupin and delphinium. For a like reason its presence is invaluable among shrubs, as the anemone flowers are well displayed against the flowerless branches. It is, however, when opportunity occurs for planting on a lavish scale, as in wild gardening, that Anemone japonica merits to the fullest its popular name of Windflower. Then it presents a spectacle of such beauty that one would travel far to see.

Under any of these conditions the ground should be deeply worked before planting, incorporating a moderate dressing of old farmyard manure, and some light material where the natural soil is inclined to heaviness. The ideal soil for Anemone japonica is a chalky one. I have known it flourish in this material, where soil, in the ordinary sense was conspicuously absent, and manure never deamt of; yet under these apparently adverse conditions it developed luxuriant masses of leafage two feet in height, and the flower stems were never less than four feet high.

Beside the type, with its flowers of rose-carmine, there are others in which this colour varies. Mont Rose has received the imprimatur of the Royal Horticultural Society, and it is practically a double flower of largest size, coloured silvery-rose, with lilac reverse; Koenigin Charlotte has semi-double flowers over three inches across, the segments coloured flesh-pink, and deepening to a pale shade of rose; Prince Heinrich is another semi-double form, not so tall as the type, but with larger flowers of a deep, rich carmine-red.

A BEAUTIFUL BED OF THE JAPANESE WINDFLOWER (ANEMONE JAPONICA).

The white forms are most chastely beautiful, as even in the bud stage these look like inverted pearl-drops. Alba, also known as Honorine Joubert, was the earliest white form, and is still worthy of a place in the garden, as it flowers freely, and continues right up to the time it is cut down by frost; Lady Ardilaun is one of the best, with large flowers, having thick segments of purest white arranged so as to form a faultless flower; Lord Ardilaun is also white, semi-double, compact in growth, and with darker foliage; Whirlwind is dwarf in habit, flowers semi-double, surrounded by green bracts; Geante des Blanches is a single white of the largest size, and regarded as one of the best of recent additions; Coup d'Argent has several rows of wavy segments, coloured creamy-white. Other kinds show slight variations, but those named embrace the best of the old and newer varieties. THOMAS SMITH.

Coombe Court Gardens.

ROSE MARECHAL NIEL.

I do not know of any yellow rose that can equal this in any way except in regard to flower stem. The weak flower stem, and the liability of the trees to canker are, undoubtedly, weak points, the latter being sufficient to deter many persons from growing the variety.

I know of one instance where canker did not kill or even lessen the flowering qualities of the tree. The specimen in question I saw growing in a greenhouse in Cheshire. The cankered portion of the stem resembled a very big cocoanut, and the owner informed me that the tree had been in the condition described for about twenty years, and yet it flowered so freely that he could gather blooms every week throughout the year. The tree appeared to be in very good health, notwithstanding its badly-cankered stem. The roof space covered measured nearly five hundred square feet.

I have grown this lovely rose under glass for many years and in various forms. The best crops of blooms were secured from plants on their own roots. Both these and worked plants cankered. Those on their own roots generally cankered about the seventh year; the worked plants a little earlier. In my cases, however, the trees lost vigour, and branches soon began to die after the canker was very pronounced. In order to have a regular supply of blooms I propagated cuttings every few years, and had good-sized plants to put out.

My plan was to grow the plants fan-shaped, thinning out surplus shoots every year. The system of growing these as cordons is a good one, and perhaps the best blooms are grown on the cordon or spurred system. The Marechal Niel is a splendid rose for forcing. I have propagated young shoots, with heels attached, in a mild bottom heat early in the New Year annually, and trained the resultant shoots to form a nice bush in a 9in. pot. At this stage, the second and third year from propagation, the plants forced well, bearing medium-sized blooms very freely.

GEO. GARNER.

LEONOTIS LEONURUS.

This striking South African labiate forms a notable feature in the greenhouse during the autumn and early winter months. In the extreme West of England it is hardy in some districts, but, generally speaking, it needs protection in winter. Introduced into this country some 200 years ago, Leonotis leonurus would, after a time, appear to have become lost until it was reintroduced about 25 years since, and is now fairly well known It is an erect growing plant, which, if stopped freely when young, will form an upright bushy specimen. The oblong, lanceolate leaves are of a pale green tint, and somewhat soft in texture. They are markedly serrated, from four to five inches in length, and about three-quarters of an inch wide. The flowers are borne in large whorls at the points of the shoots, there being a considerable space between each whorl. From their orange-scarlet colour they are very conspicuous. Propagation is an easy matter, as cuttings of the young shoots strike root readily in spring, and the plants may be given much the same treatment as a chrysanthemum during summer.

S. W.

PRUNELLAS.

The members of the genus Prunella, commonly known as Self-heal, constitute a small family of dwarf border plants, some of which are also suitable for the larger rock gardens. They are quick growing, soon forming a dense carpet of creeping stems and foliage, with numerous erect spikes of somewhat attractive flowers, all through the summer months. Among the easiest of plants to grow, any light, rich, and well-drained soil will suit them, and they may be increased freely by means of division in autumn or spring, or by means of seeds, which most of them freely produce. The Common Self-heal (P. vulgaris) is a common plant in our pastures, and an unwelcome subject in any well-kept lawn. Apart from this native plant there are only two others grown in gardens.

P. grandiflora is a European species, with large, handsome, purple spikes, produced from June to September. It is the largest-flowered kind of all, and there are many varieties of it. P. g. rubra has beautiful red flowers, while P. g. Webbiana, a handsome plant of garden origin, has bright rosy-purple flowers. It is a most effective plant for the border or the rock garden.

P. laciniata, sometimes made a variety of P. vulgaris, is very distinct, with spikes of yellowish-white flowers. It is not so strong as the above, but is very free flowering. The Common Self-heal (P. vulgaris) has spikes of flowers varying in colour from deep purple to nearly white. In habit and foliage all the above are very similar, differing only in the lobing and size of leaf.

PRUNELLA GRANDIFLORA RUBRA.

A showy herbaceous perennial with rich rose-red flowers.

TWO INTERESTING PRIMULAS.

The accompanying illustration of Primula pulchella depicts one of the newer species which are attracting so much notice at the present time. It is one of a number of charming novelties which have been introduced to our British gardens through the enterprise of Messrs. Bees, Lim., whose collectors have done so much splendid work in China and other parts of the globe. It was collected in Yunnan by Mr. George Forrest, and introduced in 1908, and only into gardens in 1911, and has, therefore, not yet found its way largely into cultivation. It belongs to an interesting section of the Chinese primulas—that of the Nicales—and has, so far, turned out to be one of the most easily-grown of this group.

As proved by one of the ablest cultivators of these primulas, Professor I. Bayley Balfour, of Edinburgh, damp is the chief enemy of this section, and the plants should be kept dry overhead during the wet months, deriving their moisture from beneath only. P. pulchella seems to be less susceptible to overhead wet than its allies, and should therefore do well in the drier districts of the United Kingdom, provided it is moist at the roots. It grows from about six to twelve inches in height, and has flowers of violet, pale purple, or lilac. The calyces of the plants in this section are usually coloured with purple, and a prominent feature in P. pulchella and others of the same section is the presence of farina (golden in P. pulchella) as a lining of the long calyx segments. The underside of the leaves, which are not at their full length until after flowering, is also coated with a charming golden farina.

P. pulchella makes a capital plant for growing in pots in a cool or cold house, where it may be planted in loam, peat, or leaf-soil or sand. In the open it should be grown on a rockery in a similar soil, and it is desirable to cover it with glass to throw off the rain in winter. It is as yet scarce and expensive. Propagation is effected by division, or by seeds if these can be ripened. P. pulchella flowers about the same time as P. sikkimensis, i.e., in early summer.

Primula sibirica.

Though our gardens are being rapidly enriched by the influx of new primulas from the East, we find that there are many of the older and longer-known species which have not yet found their way into places where we should expect to find them. Some of them are quite easy to cultivate, and they have about them a beauty and a charm which soon endear them to the cultivator.

Such a species is Primula siberica, which is well figured in the accompanying illustration from a photograph. It was introduced as far back as 1818, so that it is surprising that it has not been more largely cultivated, especially as it is by no means so difficult to grow as many primulas which are more frequently seen in gardens. It can be grown on the ordinary rockery, always provided that it has plenty of moisture during summer, but it prefers a moist, rather boggy position, and there will not only grow better, but will increase with more freedom, and will produce much finer flowers. It has been well said that P. siberica resembles the favourite P. involucrata, and this is the case, both with regard to its appearance and its requirements. It grows from three to six or eight inches high, and has pale green leaves without any farina, and rather elliptical or ovate leaves, which are either entire or are obscurely toothed. The scape or flower stem is slender, and bears a number of flowers in a loose umbel. They usually open with us about May, and are of a light lilac or rose colour.

The plant is rather variable in hue, and also in several other respects, and several forms have been described by different botanists. The principal variety is called P. sibirica var. integrifolia, which must not, however, be confounded with P. integrifolia of Linnæus, quite a different plant. The variety known as P. sibirica var. Finnmarchiana has dark lilac flowers, and has longer pedicles and lanceolate leaves. Another variety, P. s. arctica, has smaller flowers. P. sibirica is very widely spread in Nature, and extends through the Himalayas to China, where it is found in several provinces, and the Arctic regions of Europe, Asia, and America. It is easily raised from seeds or increased by division. A soil of loam and peat or leaf-mould, with a little sand added, will suit this primula well.

Dumfries. S. Arnott.

PRIMULA PULCHELLA.
One of the newer species, with violet-coloured flowers.

DAHLIAS AT CHRYSANTHEMUM SHOWS.

After twenty-five years experience on the committees of horticultural societies, I quite realise the difficulty of providing classes that will prove an additional attraction to cultivators and the public. Orchids, carnations, zonal pelargoniums, and winter-flowering begonias find a place in most schedules, in addition, of course, to the chrysanthemums, fruits, and vegetables. The last week in October and the first week in November are rather late in the season for staging dahlias, but there have been thousands of fine flowers as late this autumn, and I feel sure, if classes are provided, these flowers will be well staged. Cultivators will protect their blooms in adverse weather. To begin with, societies might provide an open class for a display of dahlias in a given space. Other open classes might be listed for cactus varieties, singles, and pompons, etc., as well as for local classes. I think the inclusion of dahlias would prove a great attraction and win a lot of extra support for our many chrysanthemum shows. Perhaps some of our expert growers will give their opinion.

Geo. Gardner.

EFFECTIVE HARDY PRIMULAS.

Primulas are coming to the fore for garden decoration, and my few general notes may serve as a reminder to garden lovers to use this splendid group of plants more freely. For beauty, attractiveness, colouring, and interest primulas are surpassed by few other plants, and the wealth of species and varieties in cultivation, and the splendid new forms introduced from the mountain ranges of Western China, suffice to create a keen interest in the family.

What I wish particularly to enforce are the splendid possibilities of the hardy primulas for creating delightful garden effects; and there is no reason why the more telling species should not be planted in masses, by the hundred or thousand, in the same way as polyanthuses and cowslips.

The one primula that has forced its way to the front in advance of its fellows as a subject for creating garden colour is P. pulverulenta. This is a grand plant, and as grown in large quantities at Easton Lodge, and elsewhere, there is nothing to equal it for effect at its season of flowering. For waterside, woodland, or wild garden planting P. pulverulenta is ideal.

The question arises, Can we utilise other primulas so freely, and, if so, what can we select? The answer is obvious, and there are many primulas we can choose for our purpose.

To take a few: The creamy-white form of P. pulverulenta, known as Mrs. Berkeley, should prove of distinct value. Lissadell Hybrid and Unique, two fine hybrids with the blood of P. pulverulenta in them, should become extremely popular. Another fine favourite will be P. Bulleyana, with its wealth of golden-orange blossoms and stout leafage, a grand primula of the greatest possible value for massing and contrasting. Grand, too, are P. Poissoni, rosy-mauve, with a golden ring at the eye, and P. Beesiana, which is splendidly floriferous, and produces its reddish-purple flowers in tiers, like most of the preceding forms.

The Himalayan Cowslip, P. sikkimensis, with its charming fragrance and drooping yellow blossoms, intermingled in a stream-side grouping with the rosy-purple P. vittata and the claret-hued P. secundiflora, provides one of the daintiest garden-pictures imaginable. The use of P. japonica and its varieties has much to commend it, but the grower would be well advised to discard weak colours and mottled flowers. The clear colours, particularly the pinks and the deep reds and crimsons, are simply splendid when the plants are well grown.

Primula rosea grandiflora is lovely in quantity, and few flowers can approach it in rose-pink colouring. Again, the Bulgarian P. deorum is a fine plant for massing in cool ground or by the waterside.

It will be noticed that the majority of the primulas mentioned are really moisture-lovers, and their cultivation is most successful when they are grown in a fairly deep, cool, and moderately rich soil. This is so, but I do not wish readers to lose sight of the mountain primulas, which delight in rock-garden conditions. A really good selection of alpine forms grown in masses on the slopes and in the bays of the rock garden, or even used for covering low, sloping banks, will provide a feast of interest and beauty.

In closing may I also urge the free use of showy primulas in beds cut out in the grass. In such cases one species should be grown in each bed, but if a succession of beauty is wanted a planting of montbretias, gladioli, or similar subjects will provide colouring during late summer.

Claeton. P. S. HAYWARD.

EVOLUTION OF WINTER-FLOWERING BEGONIAS.

Sir Harry J. Veitch recently exhibited a beautiful series of winter-flowering begonias before the Royal Horticultural Society's Scientific Committee, to illustrate the evolution of these useful and beautiful plants from the original forms. Begonia socotrana, a species discovered in Socotra by Professor I. Bayley Balfour, and brought to England by him under some difficulties owing to the Phylloxera orders in existence on the Continent, was crossed with one of the tuberous forms, which had been retarded for the purpose, by Mr. John Heal. B. socotrana, which was shown, flowers normally at this season, and it imparted this character to the seedling from the cross. The first of these was John Heal, a very floriferous variety with rather small flowers. This was crossed again with tuberous forms, and others raised, including Mrs. Heal, and later double-flowered forms and plants with quite large flowers and of a variety of shades, but none pure yellow or pure white so far. Along with the increase in size there was at first a drooping habit of floreseence, but this was corrected by crossing back on to the original species, B. socotrana, which carries its flowers erect. B. socotrana does not appear to have handed on its peltate leaves to its offspring, but its persistent floral leaves are seen in the new forms, which retain their flowers for more than a month, until they fade without dropping. The committee unanimously recommended a Certificate of Appreciation to Mr. John Heal for the remarkable and successful work he had accomplished in raising these decorative plants.

PRIMULA SIBIRICA.

A beautiful primula with bright lilac flowers.

WORK FOR THE WEEK.

STOVE PLANTS.

PROPAGATION.—When preparing for the winter work of cleaning the house, it will be necessary to get rid of surplus and worn-out plants, and although this is by no means the season for general propagation, batches of easily-rooted subjects, such as Panicum variegatum, Pilea mucosa, Fittonia argyroneura, etc., grown chiefly for edging purposes, may be inserted now. These will soon be nicely rooted, thereby liberating the propagating frame in good time for general propagation. Coleuses will also root easily, and inserted now will make a useful early batch.

STREPTOCARPUSES. — Where a very early batch is desirable a selection may be made of the young plants now in 54-size pots. Remove a little of the old surface soil and add fresh loam, leaf-mould, and sand, to which may be added a little fine bonemeal. They may then be transferred to a house in which a temperature of not less than 60 degrees is maintained. In these pots they will make a good display during early spring, or, if considered desirable, they may be given a shift when growth has well commenced.

GLOXINIAS.—A selection of the earliest ripened tubers may now be made to provide the earliest batch of these valuable stove flowering plants. First see that the drainage is in good condition, then, with a label or pointed stick, remove as much of the old soil as possible without damaging the tuber. Top-dress with fresh, rich compost. At this season no better place will be found for gloxinias than the stove shelf. Little water will be needed for some time.

GENERAL REMARKS.—Now that the days are short and dull, and even stove plants are more or less resting, it is advisable to guard against high temperature, and the unnatural conditions attached thereto. In the stove 65 degrees on dull days and mild nights is quite a sufficient temperature. Damping down will rarely be necessary, and should not be practised during a low temperature. Keep the intermediate house temperature a little lower, and take advantage of every opportunity for slightly opening the roof ventilators a little while in the middle of the day.—H. PRIME, Hatfield Gardens.

THE ORCHID HOUSES.

DECIDUOUS DENDROBIUMS.—Where the early-flowering species and hybrids of deciduous dendrobiums are required to flower early in the coming year, it is desirable that a selection of the most forward plants be made at once, and those selected should be placed where they may have the necessary encouragement. It is not always an easy matter to induce the plants to flower satisfactorily thus early in the season, for if the pseudo-bulbs have not matured and ripened properly there is generally a tendency to produce growth where flowers were expected. A sudden removal from the resting conditions to a warm, humid atmosphere is bad practice; when in the warmer divisions give only sufficient root moisture to keep the pseudo-bulbs plump until the flower-buds are distinctly distinguishable, then ample moisture may be afforded. Keep the plants in a position where they may have the full benefit of all available light.

IN THE COOL HOUSE, it is desirable that ample ventilation should be afforded. The mild weather up to the time of writing has been such that very little artificial heat has been needed, even in the North East of England. Watering and damping have had to be done with considerable discretion, and one would now welcome colder and drier weather, which would cause the atmosphere to dry more rapidly. The greatest trouble during such mild, moist periods is the spread of black rust or mould (Gloesporum Bidgoodi). No disease is more injurious to the foliage of orchids, and the rusty appearance is due to the presence of spores. There is no known cure for this trouble, and micro-photographs which I have by me (taken by the late Mr. John Bidgood, who first discovered its havoc among the plants) clearly indicate the destruction of cells, which can only end in the death of the leaf. It is therefore desirable, wherever this pest is discovered, to immediately cut off any affected leaves and burn them.—H. J. CHAPMAN, Oakwood Gardens.

FRUITS UNDER GLASS.

POT VINES.—If started as recommended some weeks ago the earliest pot vines will now be progressing fast. Let the forcing be conducted as much as possible during the day. Renovate the fermenting material if the heat has declined, as it assists the roots of the vines, and creates a more natural atmospheric moisture. Pay due attention to disbudding, and, as soon as the leaves have developed, cease syringing the vines, but continue to syringe the walls and other available surfaces. The temperature may now range from 55 to 60 degrees, according to the weather, until the vines come into flower, when 65 to 68 degrees should be maintained, with 5 to 10 degrees higher during day, with sun-heat. Keep the house considerably drier during the time the vines are in bloom, and take advantage of the maximum temperature for fertilising the flowers; cross-fertilisation is advisable, and a camel's-hair brush or rabbit's tail, with Black Hamburgh pollen on it, should be passed over the other varieties from day to day until the bunches have set. Tying down must be very carefully done, but there need be no hurry if the foliage is kept just clear of the glass, as the shoots may easily be tied into their proper position later, when all danger of breakage is past. Water the vines with tepid water, and with weak liquid manure and other stimulants as they appear needful, as these will play an important part in carrying the grapes to maturity. In the management of the rods and laterals it is most important that a good spread of healthy foliage be maintained. Stop all shoots at the first joint beyond the bunch, except where it is necessary to fill up some vacant space.

PERMANENT VINES.—Much of what I have recommended for pot vines applies to permanent vines, only that more attention is required in regard to watering the former. Disbud when ready, cease syringing the canes, and supply the necessary moisture by damping down all available surfaces. The first Muscat house should be closed this month to obtain ripe grapes next June.

LATE PEACH HOUSES.—These houses must be kept fully ventilated night and day, unless there is any danger of frost reaching the pipes. Pruning and cleaning should be pushed forward where time and labour will allow, or may be held over for bad weather, as such houses will be retarded as long as possible. Meanwhile, any alterations or additions to be made to the borders may be carried out in weather favourable to the disturbance of the roots. As the best month for planting has gone by, such work should, in most cases, be deferred until February; but so accommodating are regularly root-pruned peaches and nectarines that they may be lifted at any season, during mild weather, with every chance of the success of a crop the following season. Follow out the instructions given in my notes of October 11.—F. JORDAN, Warter Priory Gardens.

THE FLOWER GARDEN.

GENERAL WORK.—At this season of the year we expect wintry weather, and when this comes it at once puts a check to planting, turf laying, and, when very severe, to most ground work. At such times endless odd jobs should receive attention, so as to relieve the stress at busier seasons. When the elements make work outside an impossibility, stakes which were put away hurriedly can be re-sharpened, painted, graded, and tied into bundles; seedling boxes, labels, birch brooms, etc., can be made; while during spells of sharp frosts such operations as wheeling, squaring and turning refuse heaps, burning rubbish, tree lopping, and thinning, etc., usually afford ample employment.

VACANT GROUND.—There will now be many vacant plots of ground recently cleared of spring bedding plants, dahlias, annuals, and various summer-flowering subjects. The first opportunity should be taken to give these a good dressing of rotten manure, and have them well dug, keeping the surface as lumpy as possible, to allow free access of frost and air. Consideration must be given to the nature of the subjects which are to occupy the various sites during the coming season, as some will require to be specially treated. Quarters which are to be allotted to sweet peas must be deeply trenched and heavily manured; if it is decided to grow them in rows, and time and labour does not permit the working of the whole of the ground to the desired depth, take out trenches 3 feet wide and 3 feet deep, afterwards returning the soil, mixing with it a liberal supply of good rotten manure. For sweet peas in clumps, the stations should be prepared in a similar manner, taking out holes 3 feet to 4 feet in diameter. Dahlias respond to good cultivation, and their sites for next season should be trenched and well manured.

GARDEN PATHS.—Gravel paths may often be improved by turning the gravel, unless they are in such a state as to necessitate re-gravelling; the present time is an opportune one for giving attention to this work, as probably the paths that are to be treated can be isolated with less inconvenience at this season than at any other. When gravel is being turned or replenished, it is essential that a uniform surface is obtained before commencing to roll it down; round up the centre of the path sufficiently to throw the water to the sides and gratings. All traffic must cease over the freshly-rolled gravel until it has become consolidated. Much annoyance is often caused when paths are not provided with ample means for carrying off storm water, consequently, on level stretches, the gravel along the sides becomes discoloured and infested with moss and weeds. This should be remedied by increasing the number of gratings and catch pits, and providing enough fall towards the gratings to carry off all surface water. Such insufficient provision is, however, often most noticeable on steep paths, the surface of the gratings being too small to carry away a flush of water, and so the gravel is washed out of place after every storm.

SUMMER BEDDING PLANTS.—Fuchsias and heliotropes which are being grown to form specimens for bedding-out pusposes must receive every encouragement. A temperature of 55 to 60 degrees should be maintained by fire heat, and every advantage taken to syringe the plants overhead on all fine days. Occasional applications of soot-water will be most beneficial. Give due attention to staking, tying, and pinching the young growths. Subjects such as pelargoniums, lobelias, iresine, coleus, etc., must be given a light position, and kept in a dry condition until the days lengthen. Dahlias, Salvia patens, begonias, gladioli, etc., should be inspected occasionally—T. B. FIELD, Wych Cross Place Gardens.

ROSES FOR GARDEN DECORATION.

(Continued from 927.)

Lifting and Replanting.

Roses should be lifted and replanted at least once every fifth year, and for several reasons, perhaps the most important being that it enables the rose quarters to be remade and a further supply of the necessary rose food in the shape of manure and fresh loam dug into the beds. It is impossible to do this properly unless the plants are lifted. Another reason: by lifting and root pruning we encourage fibrous root growth. It is generally known that a mass of fibrous roots convey more food to a plant than a few strong coarse roots, owing to the fact that roots feed only through their root hairs, which are necessarily far more plentiful on a large number of fibrous roots than on a few coarse ones. It is obvious, therefore, that we should strive for fibrous roots, and the best way to obtain them is to lift and root prune. By so doing I am confident you will add strength and many years to the life of the rose plants. These remarks on lifting and replanting do not apply to climbing roses, which are best left undisturbed.

Other Ways in which the Rose May be Grown.

As isolated specimens, on the lawn or even in the foreground of a shrubbery, some of the stronger growing sorts are highly attractive. I would mention Gruss an Teplitz; the rugosa, Conrad F. Myer, Macrantha (charming single pure white), Mrs. Stewart Clark, Bardou Job, Beauté de Lyon, Zephyrine Drouhin, Maharajah, Hon. Ina Bingham, Commandant Jules Gravereaux, and Juliet. All these varieties also look extremely well when planted in large groups, say fifteen feet across, and make a mass of colour not easily forgotten. The pruning of plants grown in the way suggested will be entirely different (after the first year) to that of bedding roses. Here you let them grow much as they please, just thinning out where necessary and shortening back the unripe tips of the shoots. A very fine feature may be made in a garden by pillar roses, that is, roses trained up either single posts or tripods. Roses grown in this manner and properly placed help to break up the level of a rose garden, are fine subjects for the back of herbaceous borders, and may be used with advantage in many parts of the pleasure grounds. The stronger growing roses—of which my choice for this purpose includes American Pillar, Excelsa, Blush Rambler, Dorothy Perkins, Carmine Pillar, Jersey Beauty, Alberic Barbier, Hiawatha, Gardenia, Hélène, Evangeline, and White Dorothy—should have pillars at least 10ft. high for them to ramble over, while if shorter pillars are used, say, posts 6ft. in height, the following may be considered the best twelve: Lady Waterlow, Madame Pierre Cochet, Zephyrine Drouhin, Florence Haswell Veitch (one of the newer roses, brilliant scarlet colour and very fragrant), Papillon, Trier, Wallflower, Madame Alfred Carriere, Ards Rover, Longworth Rambler, Lucy Bertram Sweet Briar, and Gruss an Teplitz.

Every garden should possess at least a few standard weeping roses. Very beautiful are many of the Wichuraiana roses when worked on high standards, with their long trailing growths drooping to the ground and covered with thousands of blossoms. Talking of standard roses, I would remind you when ordering this class of rose of the importance of ordering varieties which do well when grown as such. Some varieties will not make standards, and some are better as standards than as dwarfs. One such I think is White Maman Cochet, another is William Shean. Both of these when grown as dwarfs droop their flowers so much that unless you lift the blooms up you cannot see them, and owing to this fault after a storm they are so badly splashed that they are spoilt. Others that make really good standards are Lady Ashtown, Madame Jean Dupuy, Frau Karl Druschki, Gustave Grunerwald, Hugh Dickson, General McArthur, Caroline Testout, Grace Darling, La Tosca, Lady Hillingdon, Madame Abel Chatenay, Mrs. Foley Hobbs, Mrs. Sharman Crawford, Marie van Houtte, and J. B. Clark, and there are, of course, many others.

I have not touched upon roses for hedges, house decoration, or yet roses for walls and pergolas, but I should like to advise you, with regard to pergolas, to be careful where you build them. Nothing, to my mind, looks more out of place than a pergola "starting from nowhere and leading to nowhere." If you can understand me, a pergola should have a definite starting point, and lead to some other definite feature of the garden. If your garden is too small to arrange this be content with arches, which are infinitely more in keeping with a small garden.

Fragrance.

The remark is often made that "our newer roses are lacking in fragrance," and to back up this opinion our good friend Frau Karl Druschki is made the scapegoat. Well, however much Druschki errs in this respect, I would remind you that she is no longer a new rose, but a "thirteen-year-old," and if she sins by lacking scent, so, too, do the old white roses Merveille de Lyon and Marchioness of Londonderry, and Druschki is a long way in advance of these older varieties in every other way. I think there is a good deal of nonsense talked about this matter, for can anyone tell me a sweeter rose than Hugh Dickson, introduced in 1904? Then, how about Rayon d'Or, introduced in 1910; Lady Alice Stanley, in 1909; Commandant Felix Faure, 1902; Beauté de Lyon, 1910; Richmond, 1905; General McArthur, 1905; Avoca, 1907; Chateau de Clos Vougeot, 1908; His Majesty, 1909; Edward Mawley, 1911; and George Dickson, 1912, taking a few at haphazard? I cannot help thinking that these and many others, all introduced during the last ten years, are equal at least in fragrance to the best of the old varieties. Of the old varieties the sweetest I know are Zephyrine Drouhin, La France, Senateur Vaisse, Mrs. J. Laing, Charles Lefebvre, Horace Vernet, and Marie Baumann, and, of course, the old Cabbage or Provence rose and the old common Sweet Briar, but even with the Sweet Briars we have our modern development in the Penzance Briars, many of which are quite as sweet as the old-fashioned variety.

(To be continued.)

WELL HEADS IN GARDENS.

Frequently, by force of circumstances, a well happens to be situated either in close proximity to a dwellinghouse, or in a conspicuous position in the garden, and in these cases it is desirable that a means of protection be designed with a view to artistic effect as well as efficiency. Illustrations of elaborate well-heads in stone have appeared in the pages of THE GARDENERS' MAGAZINE, and these are, of course, the correct thing where the well is in a formal garden. Equally artistic, although totally different in character, is the subject of our present illustration, reproduced from a drawing of a well-head, cleverly designed by Messrs. Boulton and Paul, Lim., Norwich. The circular guard of brickwork is surrounded by stone-paving, and the whole covered by a heather-thatched roof, which is supported by stout oak posts. The material, design, and construction are all appropriate to the surroundings, and, consequently, the well becomes a fine feature in the garden scheme, instead of—as it might have been—an eyesore.

AN ARTISTIC WELL-HEAD.
Designed by Messrs. Boulton and Paul, Norwich.

Christmas Holidays.—The publishers wish to inform readers that, owing to the usual day of publication clashing with the Holidays, next week's GARDENERS' MAGAZINE will be on sale Wednesday, December 24.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

National Rose Society.

The annual meeting was held at the Westminster Palace Hotel, Westminster, at three o'clock on Thursday, December 11. The President, C. E. Shea, Esq., presided, and there was a large attendance, including a considerable number of prominent trade and amateur rosarians. The room did not appear to be a very suitable one for such a large gathering, as the members were crowded, and there was a sound of preparations for the conversazione beyond the screen.

After the usual preliminary formalities, Messrs. C. C. Williams and H. E. Mount were appointed scrutineers of the ballot for the forty-two seats on the Council.

Before Mr. Mawley read the anual report, he read a telegram from Mr. E. T. Cook, President of the National Rose Society of Canada, who landed that day at Liverpool, but too late to permit him reaching the meeting; however, he sent good wishes from his society.

REPORT OF THE COUNCIL FOR 1913.

In presenting their report the Council have pleasure in stating that during the past twelve months, with one exception, more new members have joined the society than in any previous year. This is most encouraging as it shows that the advantages now offered to those interested in roses and rose culture in this country and elsewhere are becoming each year more generally known and appreciated. For the first time in the history of the society the number of members exceeds 6,000.

In order to encourage rose culture under glass, a new departure this year was made by holding a spring show in the Royal Horticultural Hall, Westminster, on May 1. Considering it was the first exhibition of the kind ever held in this country, and that the cold and sunless weather somewhat upset the grower's calculations as to the date, it must be regarded as having been, on the whole, a success, and, judging from the interest displayed by the members and their friends in the exhibits, this spring rose show of the society promises to become an extremely helpful and popular exhibition.

The Metropolitan Show again took place, by the kind permission of the President and Council of the Royal Botanic Society, in their beautiful gardens in Regent's Park, the date of the exhibition being July 4. Favoured by the season and the weather on and before the show day, this proved the largest and finest exhibition the society has ever held. The attendance of members and their friends was also larger than on any previous occasion. It is much to be regretted that the society's Royal patroness, Her Majesty Queen Alexandra, was unable to visit this grand exhibition and inspect the magnificent display or roses.

The Provincial Show took place at Gloucester on July 15. This, too, was a fine and extensive exhibition; indeed, larger than either of the three previous Provincial Shows. The arrangements for the exhibition were excellent, and admirably carried out by the hon. secretary, Mr. W. H. Pickford, assisted by other members of the local committee.

The Autumn Exhibition, held in the Horticultural Hall, Westminster, on September 11 and 12, proved one of the smallest and least attractive shows of the kind the society has yet held. This was no doubt owing to the dry and otherwise unfavourable weather, so far as roses were concerned, during the summer and early autumn of this year.

During the past year the "Rose Annual for 1913," containing for the first time some coloured illustrations, was distributed to the members in April, while a new edition of the "Official Catalogue of Roses" was sent out in November. The warmest thanks of the Council, and also of the members generally, are due to the members of the Publications Committee, who each year devote so much time and care in their endeavours to make the publications of the society as complete and helpful in every way to the members as possible.

At the last annual general meeting the Dean Hole Memorial Medal was awarded to Mr. George Dickson, of Newtownards, Co. Down, Ireland, for the great services he has rendered to the rose during the past half century in raising so many new roses of special merit, and as one of the most successful pioneers in the scientific hybridisation of roses.

The number of societies in affiliation with the National Rose Society is now fifty-five, or about the same as in the previous year.

The Council record, with regret, the death in January last of Mr. Alfred Tate, since 1904 a vice-president of the society, and a keen rosarian. His rose garden at Leatherhead was the largest and finest in the kingdom, and his exhibits of decorative roses were the best ever staged by an amateur. He was regarded with the highest esteem by all who knew him.

They also regret to announce the death in October last of Mr. J. T. Strange, whose genial nature endeared him to all with whom he came in contact in the rose world. He was one of the society's oldest members, having joined the National Rose Society in 1877, when he was at once elected on the Council, and last year he became a vice-president of the society.

Judging by the amount received in gate-money from the general public at the exhibition in the Royal Botanic Gardens, there was a good attendance of visitors. The receipts from all sources during the past year, including a balance from the previous year of £442 12s. 2d., amounted to £4,061 6s. 5d., and the expenditure to £3,586 10s. 6d., leaving a balance at the bankers of £474 15s. 11d., after £500 had been placed to the reserve fund, which now stands at £2,000.

During the past year 1,045 new members have joined the society, or a greater number than in any previous year except 1910, when the number of new members was 1,050.

The Spring Show will be held in the Royal Horticultural Hall, Westminster, on Thursday, April 23; the Metropolitan Exhibition, in the Royal Botanic Gardens, Regent's Park, on Tuesday, July 7; the Provincial Exhibition, at the invitation of the Mayor and Corporation of Bath, in the Sydney Gardens, of that city, on Thursday, July 16; and the Autumn Exhibition at the Royal Horticultural Hall, Westminster, on Thursday, September 24.

The "Rose Annual for 1914," which will contain a number of helpful articles on rose culture, etc., and, in addition to the usual illustrations, will have six page illustrations by the three-colour process, will be issued to the members as early in the spring as possible, together with the new edition of the "Enemies of the Rose," and admission tickets for the spring show. A new edition of the "Hints on Planting Roses" will be sent out to members with the "Arrangements for 1914," together with their tickets for the metropolitan, provincial, and autumn shows, and in December with the notice of the annual meeting will be sent a new and revised edition of "The Handbook on Pruning Roses."

To the donors of special prizes the council offer their grateful acknowledgments. Their thanks are also due to the local secretaries. Among the most successful of these in obtaining new members they may mention Mr. A. E. Hayton (South Africa), Captain Kilbee-Stuart (Newbury), Mr. G. C. Sawday (Weybridge), and Mr. F. J. Woods (Weston-super-Mare), and more particularly Mr. R. E. West (Reigate), who, during the past year, induced no fewer than 64 of his friends and acquaintances to join the society.

GEORGE W. COOK, Hon. Treasurer.
CHARLES BRANNAN,
Chartered Accountant.

12, King Street, E.C.
December 9, 1913.

The President, in moving, "That the report and financial statement be adopted, printed, and published," referred briefly to the splendid position of the society, its record number of members, and its great financial success, as well as its record of exhibitions. He pointed out that never before had so large a sum by £200 been placed to reserve. Altogether, he had the greatest pleasure in moving the adoption of the report. Mr. Frank Cant seconded the motion, and spoke of the good work done by the distribution of literature to members, and the splendid financial position of the society.

Mr. Lewis Pawle thought it was unwise on the part of the council to continue to invest in Consols, and he moved that no more money be so invested. Mr. Johnson suggested that ladies should be eligible for seats on the council, and he urged that the present system of voting by a mere handful of members present be altered as soon as possible to one of postal voting, so that all members could vote instead of 5,000 of them being disfranchised. Mr. W. J. Grant was in sympathy with the last speaker in reference to voting. Mr. Holland did not agree with the suggested system of postal voting, and said that it was open to members to send in nominations for the council, and to include ladies in their nominations. Another member suggested that rosarians of distinction might be placed on the council "causa honoris," and the president pointed out that there were honorary vice-presidents. Other members spoke, and one referred strongly to the noise at the back of the room, as observed by us in our opening paragraph.

The motion was put, and carried unanimously, and the President then moved that an honorarium of £150 be offered to Mr. Mawley, the society's hon. secretary; this was seconded by Mr. W. A. Cook, who spoke very highly of the splendid work done by Mr. Mawley for the society. The motion was carried with acclamation.

ALTERATIONS OF RULES AND BY-LAWS.

Several alterations of rules were proposed, and carried with little discussion, as they were chiefly verbal alterations; but a lengthy discussion ensued over the everlasting question of the constitution of an amateur. By-law No. 7, after describing a nurseryman, proceeds to define an amateur, and points out that "no person shall be allowed

to compete as an amateur who sells rose plants, rose blooms, or buds for budding." To this definition it was proposed to add, "As exceptions to the foregoing, (a) an amateur may sell his rose plants when giving up possession of the garden or place where they have been grown, and (b) an amateur may sell new seedlings or sports of his own raising, but only to nurserymen. No person shall be allowed to compete as an amateur who is a resident member of a household where a nursery business is carried on, nor any person who issues a catalogue or price-list of roses, buds for budding, or other horticultural produce."

Dr. Williams and Mr. E. J. Holland moved and seconded this matter, but it was strongly opposed by Dr. Waddell and Mr. Johnson, the former moving as an amendment the insertion, after "or price list of roses," the words, "other than new seedlings or sports of his own raising." His argument, so far as we could gather, was that if the proposal was carried it would prove a great hardship to those amateurs who were raising new roses and desired to recoup themselves for the time and trouble expended. Dr. Waddell, it seemed to us, spoiled his case by stating his belief that the traders had a vested interest in the N.R.S., and suggesting that the proposition was entirely in their favour and altogether against an amateur raiser. His remarks were greeted with many objections from amateurs and traders alike. The Rev. J. H. Pemberton said he was the culprit, and it seemed to him that the trade were afraid of the amateurs, and desired to have the sole option of purchase of new roses. If the proposal was carried, he could no longer compete as an amateur. Mr. George Paul said the matter was one for amateurs to settle among themselves, and he believed the trade would refrain from voting on the subject. Eventually the amendment was put and lost, and the motion was put and carried by 33 votes to about 7, and, so far as we could see, the traders did not vote either way.

The President declared the election of officers and council, the only alteration on the list being that Mr. Felton gives way to a newcomer.

The conversazione being long overdue at this point, the members quickly dispersed to join their friends and other members gathered in large numbers beyond the screen, and even forgot to thank the President for presiding.

Royal Horticultural Society.

The three standing committees met at the Royal Horticultural Hall on December 16, but, with the exception of the Orchid Committee, they had little to do. This latter body had a large number of exhibits before it, and crowded in one end of the Library the members carried out their duties with some difficulty.

One Award of Merit, to Carnation Philadelphia, from Messrs. W. Wells and Co., Merstham, was granted by the Floral Committee. The Orchid Committee granted a First-Class Certificate to Cattleya Percivaliana alba var. Lady Holford, from Sir George Holford, Westonbirt, Tetbury; and Awards of Merit to Cypripedium Charlesianum smaragdinum, from Mr. F. J. Hanbury, East Grinstead; to C. Bourtonensis, from Mr. G. F. Moore, Chardwar, Bourton-on-the-Water; to Odontonia Langowoyi, from Messrs. Charlesworth and Co., Haywards Heath; and to Odontoglossum Cleopatra Rosefield var., from Mr. de Barri Crawshay, Sevenoaks.

SCIENTIFIC COMMITTEE.—December 2.

Present: E. A. Bowles, Esq. (in the chair), Sir H. J. Veitch, Professor W. Bateson, Professor F. Keeble, Messrs. J. Odell, A. Worsley, W. Hales, J. T. Bennett-Poe, E. M. Holmes, W. C. Worsdell, G. Wilson, J. Fraser, Dr. Voelcker, and F. J. Chittenden (hon. sec.).

POTATOES DISEASED.—Dr. A. J. Voelcker showed examples of potatoes with brown discolouration just beneath the skin, and a soft rot spreading therefrom into the tuber. The tubers had been grown at Woburn, and had been clamped; but not until after the potatoes had been some time in the clamp had the trouble been evident. Nothing had been seen of disease while the plants were growing. The tubers were sent to Wisley for further examination, along with others from Hampshire.

PELARGONIUM HYBRIDS.—Mr. Fraser showed further dried specimens from the Wisley collection, and made remarks on their origin from Pelargonium denticulatum, which appears to vary considerably in the foliage.

SEEDLINGS FROM VARIEGATED PLANTS.—Professor Bateson showed leaves of a pelargonium with a white margin to the leaf and a layer of cells just below the epidermis without chlorophyll, the seedlings of which were always complete albinos owing to the origin of the ovules from the subepidermal layer, and another leaf with tissues without chlorophyll occupying the middle of the leaf overlaid with chlorophyll-bearing tissue, the seedlings of which were all green, as Dr. Baur had shown. The well-known form of Chlorophytum elatum with a white margin to the leaf had, however, apparently produced green seedlings, while the form of C. comosum with a median white stripe down the leaf produced all albino seedlings, three of which were shown. Some conversation took place with regard to the meaning of the phenomenon exhibited by the Chlorophytum, which is not at all clear. Other examples in which albino seedlings were produced were mentioned, and analagous cases of variegation were referred to. It would be interesting to cross the white-edged form of C. elatum with a form having a median white stripe to the leaf, if such is at present in existence. One was known at one time under the name of medio-pictum, but appears to be rare, if not extinct, now. The committee would be glad to hear of its occurrence. It may be noted that the white-edged chlorophytum has no chlorophyll-less subepidermal layer.

LEAF-CUTTING BEE.—Mr. Bowles showed the foliage of horse-chestnut with the well-known circular pieces removed by this insect. No member of the committee had seen the leaves of this tree attacked in a similar way before.

APPLES SPLITTING.—Mr W. Voss, of Raleigh, showed apples which had split after they had been placed in the store. The committee were of opinion that the late rains had swollen the flesh of the apple after the skin had become set, so that the latter could not long withstand the pressure set up. Mr. Voss also sent fruits of Apple Annie Elizabeth and Cox's Orange Pippin apples affected with bitter-pit.

PRUNELLA VULGARIS ON A LAWN.—A piece of turf infested with this well-known weed was sent. It often occurs on lawns and spreads close to the ground when cut down by the mower. It is difficult to eradicate, but probably dressing at intervals with sulphate of ammonia at the rate of 1½cwt. to the acre would kill the foliage and encourage the growth of the grass. Another method suggested was to forego mowing for a time, and so permit the plant to grow tall enough to be handled and removed completely.

GROWTH ON BULB.—A bulb was sent by Miss Skelton with a curious growth on its side, apparently due to the development of numerous adventitious buds.

Midland Daffodil Society.

A special general meeting of this society was held at Birmingham on December 10, to consider the position of the society owing to the death of Mr. Robert Sydenham. The President, Mr. P. D. Williams, was in the chair, and amongst those present were the Revs. G. H. Engleheart and Joseph Jacob, and Messrs. Herbert Smith (secretary), C. L. Adams, H. D. Phillips, J. Mallender, W. A. Watts, C. H. Haynes, T. Humphreys, etc., etc. It was decided to hold no dinner in 1914, but that a meeting of members should be called for the evening of the first day's show to consider the holding of one in future years. As a memorial to Mr. Sydenham, it was decided to add to the medals, and to all the official note-paper, the words, "Robert Sydenham, Founder."

Mr. C. L. Adams was elected as treasurer, and Mr. W. A. Watts to the vacant seat on the Floral Committee.

Mr. Smith, as managing director of Robert Sydenham Limited, intimated that his firm was prepared to give the society the same help in the future as it had been accustomed to do in the past. Votes of thanks to the president and to Mr. Smith concluded the meeting.

CLAY'S
FERTILIZER
THE
STANDARD
PLANT FOOD

"THERE IS NOTHING LIKE
CLAY'S
TO BUCK THINGS UP."
The Fruit-Grower.

SOLD EVERYWHERE in 6d. and 1- TINS: and in BRANDED and SEALED BAGS — 7 lbs., 2 6; 14 lbs., 4 6; 28 lbs., 7 6; 56 lbs., 12 6; 112 lbs., 20 -.
Or direct from the Works, Carriage Paid in the United Kingdom for Cash with Order (except 6d. TINS).

Every Genuine Bag, Tin and Seal bears this Trade Mark.

CLAY'S FERTILIZER LONDON
TRADE MARK

Used at the Royal Gardens; throughout the grounds of the Royal International Horticultural Exhibition, 1912; by Government and Municipal Authorities, and by Horticulturists Universally.

Full Directions for Use are included in "CLAY'S SUCCESSFUL GARDENING" (Fifth Edition), Greatly Enlarged and containing 332 pages of valuable information by over 30 well-known Gardening writers. Embellished with Coloured Plates and bound in Cloth. Price 1 - net. Of Seedsmen, etc., or Post Free for that amount direct from the Publishers:

CLAY & SON, MANURE MANUFACTURERS AND BONE CRUSHERS, STRATFORD, LONDON, E.

National Chrysanthemum Society.

Mr. Thos. Bevan presided over a well-attended meeting of the Executive Committee of the N.C.S. on December 15, at Carr's Restaurant, Strand, W.C. Sub-Committee reports were considered, and the Schedule Committee was empowered to go ahead with the schedules for 1914. A spray of chrysanthemums was defined as follows: A spray is the last flowering growth, consisting of one stem with a central flower or bud, and its surrounding flowers or buds. The financial statement showed that expenditure and income would about reach the amounts estimated at the beginning of the year. The Floral Committee fixed the date of its dinner for January 28. The show dates arranged for 1914 were October 7 and 8, and November 4, 5, and 6; Floral Committee meetings, September 21; October 7, 19, and 26. November 4, 16, and 30; and December 9; Executive Committee meetings, September 21, October 19, November 23, December 14, and January 18, 1915.

GARDENING ENGAGEMENT.

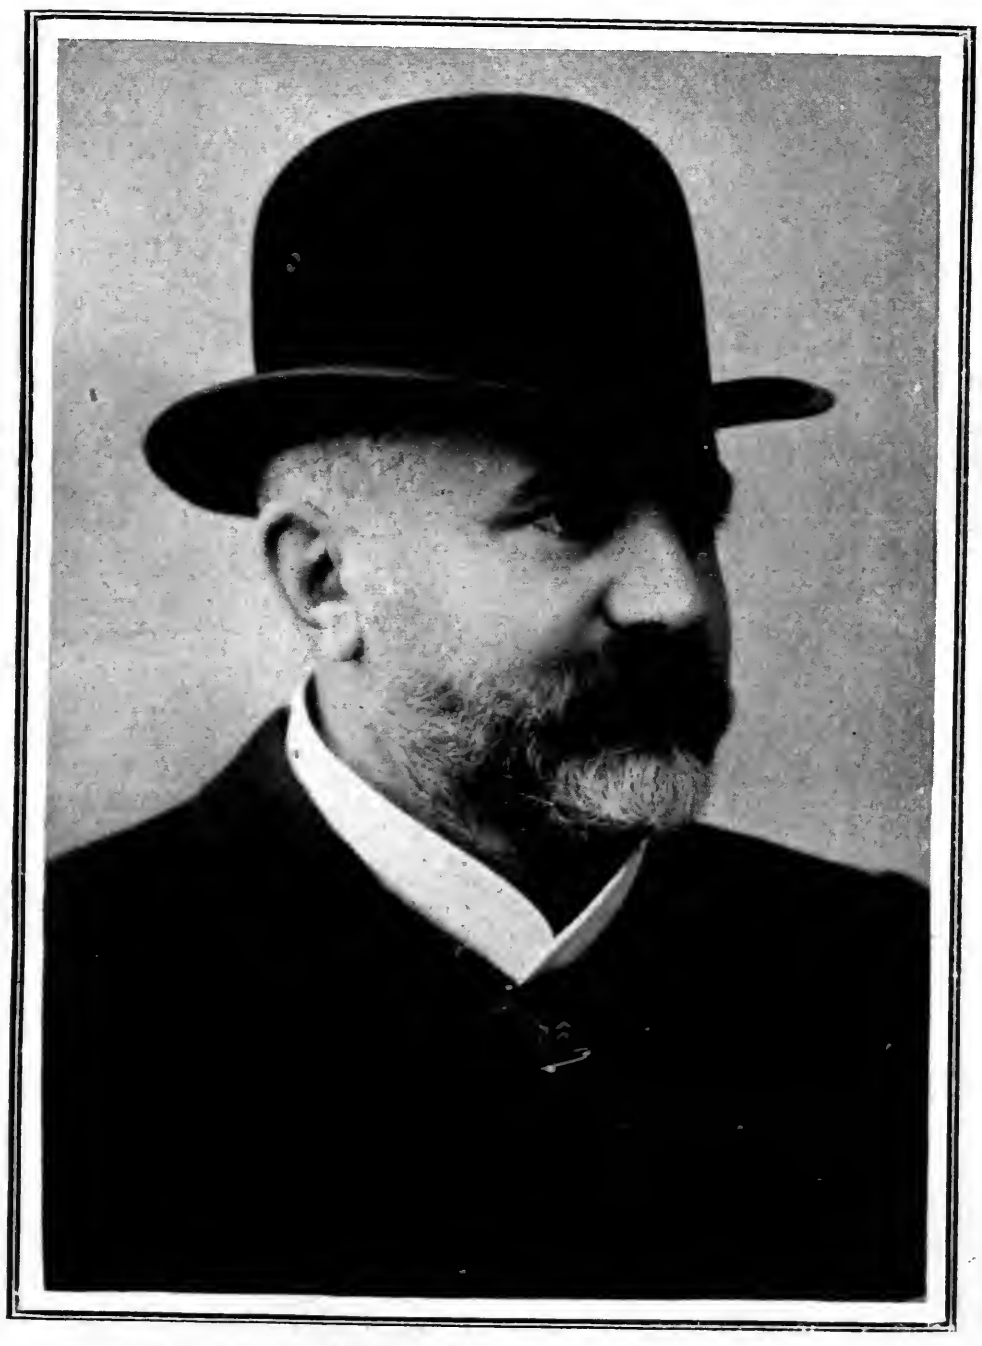
Mr. Joseph Mersh, for ten years head gardener to Major Terry, at Shepperton, has been appointed head gardener to Lady Harrison, The Priory, Beech Hill, Reading.

Travelling Home for Christmas.—Many a garden lover endeavours to reach the old home for Christmas, and large numbers of young men "off duty" for the holidays travel homeward via London. Every effort is being made now to secure comfort as well as speed, and the Great Central Railway Company specially caters for excursionists in these particulars, and even goes so far as to reserve a seat for travellers on December 24, without extra charge, if such is booked well in advance. These special express trains, well warmed and lighted, convenient, and comfortable, depart from Marylebone Station to the leading towns in the Midlands, Yorkshire, Lancashire, and the North of England.

OBITUARY.

MR. MARTIN JOHN SUTTON.

It is with very deep regret we have to announce the death of Mr. Martin John Sutton, head of the firm of Messrs. Sutton and Sons, Reading, which took place, suddenly, on Sunday, December 14, at the Piccadilly Hotel, London, where he was staying for the Smithfield Club Show. Mr. M. J. Sutton, elder son of the late Mr. Martin Hope Sutton, and brother to Mr. Arthur Sutton and Mr. Leonard Sutton, was better known in the world of agriculture than in the sphere of horticulture, and he devoted his great gifts of organisation and foresight to the development of the agricultural side of his firm's business. Among farm crops he was an acknowledged expert, and his work on "Permanent and Temporary Pastures" has become a classic.



THE LATE MR. MARTIN JOHN SUTTON.

Born in 1850, Mr. M. J. Sutton entered business when 16 years of age, was taken into partnership with his father and uncle in 1871, and became the head of the firm in 1887. For about five and twenty years he was a prominent member of the Council of the Royal Agricultural Society, and only resigned his seat when, after strong opposition, that body decided to establish a permanent show ground at Park Royal. He believed in the migratory system, and had the satisfaction of seeing it re-established to the advantage of the Society for which he worked so admirably. He did not wholly sever his connection with the Society, but continued to remain a Governor, and liberally assisted all educational efforts, and only a few days ago, at Islington, the King honoured him with a cordial personal greeting, when visiting the great Cattle Show.

Mr. Sutton was a Chevalier of the Legion of Honour, and a Knight of Grace of the Order of the Hospital of St. John of Jerusalem in England. He gave largely to educational institutions and to the Church of England. In 1904 he was co-opted Mayor of Reading, and received the honorary freedom of the borough. He was a member of the Berkshire County Council and a Justice of Peace for Reading and Oxfordshire. On his estate at Wargrave Manor, Berks, he took a keen interest in the breeding of horses, cattle, sheep, and pigs, and at the same time did not forget the attractions of his garden. Ever a generous giver, Mr. Sutton will be greatly missed because of his many benefactions in and around Reading, as well as farther afield, while his loss to agriculture is greater than can yet be estimated.

The funeral service was held on Wednesday afternoon at the Church of St. Andrew, Sonning, one of the most beautiful of riverside villages, and the large numbers present testified to the high estimation in which Mr. Sutton was held by those acquainted with the splendid services he had rendered the community in the course of his long and active life. The large church was indeed filled to its utmost capacity, and among those who had assembled to do honour to his memory were gentlemen high in the counsels of his native town and county, and representatives of the various religious, philanthropic, and scientific societies in which he had taken so keen an interest. Among the horticulturists present were Mr. N. N. Sherwood, Mr. John Collingridge, Dr. Voelcker, Mr. F. W. Harvey, and Mr. George Gordon.

TRADE NOTES.

Mr. H. Hemsley, Crawley, takes time by the forelock, and has already issued a schedule of prizes offered by him and to be competed for by his customers on September 16, 1914, at Crawley.

Mr. Charles Wall, Melrose Nursery, South Down, Bath, writes that he is afraid our reference to Carnation Lady Fuller as belonging to the Mrs. H. Burnett class may lead growers to believe the variety was raised from Mrs. H. Burnett. Our reference was to colour only, and readers will be glad to learn that Mr. Wall's fine new variety is a seedling from Enchantress crossed with a clove-scented cerise seedling he raised many years ago, and it possesses the fine habit of Enchantress and the vigour and strength of the seedling.

GLASS IS A NECESSITY IN GARDENING. The Chase system enables short glass to be instantly made into cold and plant covers which secure results unattainable by hot-jars, cloches or cold frames. Earlier crops with little attention. Less disappointment throughout year. Cheap and efficient. 50,000 square feet in use. Special shapes for Alpine Plants. CHASE CONTINUOUS CLOCHE, 67, Dale Street, Liverpool.

YORK STONE PAVING, for Garden Paths and Lily Ponds; rectangular or broken for rustic work; steps and wall coping, rockery.—GEO. VINT and BROS., Idle, Bradford.

When answering Advertisements please mention "Gardeners' Magazine."

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of THE GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Specimens of plants, flowers, and fruits for naming, or opinion, should be sent to the Editor of THE GARDENERS' MAGAZINE, 2, Adelaide Road, Brentford, Middlesex, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notifications of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in THE GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

WOBURN CAUSTIC WINTER WASH.—C. C., Barnstaple: A friend of mine wishes to spray his fruit trees this winter to relieve them of lichen and otherwise clean them, so will you kindly give me the formula for the Woburn form of caustic winter wash?—The Woburn caustic winter wash, invented by Mr. Spencer Pickering, is made up as follows: Iron sulphate, ½lb.; lime, ¼lb.; caustic soda, 2lbs; paraffin, 5 pints, and water to make ten gallons of wash. In preparing this spraying mixture the best method is to dissolve the iron sulphate in about nine gallons of water; slake the lime with a little water, and then add sufficient to make it into a milk; strain this through a piece of sacking, and add it to the iron solution. Then add the paraffin to the mixture, and stir vigorously, and, lastly, add the caustic soda. When the latter has dissolved the mixture will be quite ready for use. By the addition of paraffin the wash is rendered more effective in the destruction of Mussel Scale, while the iron sulphate ensures the emulsification of the paraffin.

KEEPING FUCHSIAS IN A DWELLING-ROOM DURING WINTER.—J. H., Blackburn: Will you please tell me how I can best keep some fuchsias through the winter? There are several plants, and I have allowed them to become quite dry at the roots; so far, they are on a shelf in a room where gas is used. Have I done right in ceasing to give water?—When keeping fuchsias during winter it is a good plan, failing a greenhouse, to store them in a shed, where they will be free from frosts. A shed is preferable to a dwelling-room, especially where gas is used. The plants may be allowed to remain dry at the roots until new growth commences in the spring.

BEGONIAS AFFECTED BY MITE.—F. G., Hastings: I enclose a small plant of Begonia Gloire de Lorraine, and should like to know what has caused the leaves and stems to turn brown. I have a good lot of plants, and several of them have turned brown like the enclosed.—The Begonia Mite is responsible for the discolouration of the leaves, and this pest can only be kept away by regularly dipping the plants in a nicotine solution, and, especially, by dusting the undersides of the leaves with tobacco dust. Once the foliage becomes discoloured little can be done to restore it, but steps may be taken to get rid of the mite.

CLIMBING PLANTS FOR NORTH ASPECT.—J. K., Northampton: In addition to the list of roses suitable for a north wall, so kindly furnished in your issue of November 29, will you further oblige me by recommending a few other climbing plants suitable for a similar position?—A fairly good number of climbing plants are available for a north wall, but it must be remembered that thoroughly cultivated soil is essential to their well-being. You may select ivies both green and variegated; Jasminum nudiflorum, which displays its yellow flowers during winter, and is very useful; Ceanothus dentatus and C. americanus, both with blue flowers; Forsythia viridissima, a pretty plant, sometimes used for the purpose; and Cotoneaster microphylla, which makes a good covering for a north wall, as also does Cydonia japonica. Lonicera Periclymenum may be planted, as well as Rubus laciniatus, which has ornamented and deeply-cut foliage, and usually gives a good crop of fruit. Cratægus pyracantha Lelandi is very serviceable, and valuable for its brilliant fruits. Ampelopsis Veitchi is another very useful subject, especially for a high wall.

PROPAGATION OF THE AMERICAN BLACKBERRY.—H. N., March: Will you please tell me how to propagate the American blackberry? I have two plants, both of which fruited this season, and they now have several long canes for fruiting next year.—The blackberry to which you refer is probably the Wilson Junior; if so, the best method of propagation is by layering, which is best done in August or September when the growths have lost many of their leaves. The growths should be pegged down near their tips, three or four inches below the surface of the soil, and when they have rooted they should be cut off and planted. It is also possible to propagate blackberries by cuttings of half-ripened growths and by the separation of sucker growths from the parent plant, but layering is the best method.

EPIDENDRUM VITELLINUM MAJUS AFTER FLOWERING.—G. L. C., Ipswich: I have a nice little batch of the late-flowering form of Epidendrum vitellinum majus; the plants have flowered very well indeed, but in some cases they have now passed their best. What I wish to know is how to deal with this beautiful orchid after it has flowered. Does it need to be dried off or kept well watered, and does it need a lower temperature? Any information you can give will be valued.—The spikes of Epidendrum vitellinum majus should not remain too long on the plants, or the latter will become distressed. When the flowers have been removed only sufficient water to keep the pseudo-bulbs from becoming shrivelled should be given. At this period the plants should be placed in a temperature ranging from 55 to 60 degrees. In the spring, when new growth commences, they require a slightly warmer temperature, and more water may be given, and at this time any plants that need repotting may be dealt with.

ORCHID CULTURE FOR AMATEURS.—N. S. C., Cambridge: Quite recently I have come into possession of a small collection of orchids, chiefly odontoglossums, cypripediums, and lycastes. I carefully read your weekly notes on orchids, but I feel I should have a small handbook by me, as I am always finding myself in need of assistance. I am very fond of the few orchids I have, especially as so many of them flower in the winter. If you will recommend me a useful book at a reasonable price, I shall be greatly obliged.—A book that will just suit your particular purpose is "Orchids for Amateurs," by C. A. Harrison; this is published by Messrs. W. H. and L. Collingridge, and can be obtained post free for 2s. 10d. from 148 and 149, Aldersgate Street, E.C.

NAMES OF PLANTS.

M. S., Sevenoaks.—Hamamelis arborea.

F. S. O., Reigate.—Eranthemum speciosum.

BARR'S SPECIAL BULB PLANTER

Rd. 548091.

Specially designed for planting Daffodils and other bulbs in grass. This tool cuts and lifts a clean circular piece of turf, which is released from the cup when the second hole is made, and lies ready at hand to fill in the holes when the bulbs have been put in, it being only necessary to remove a little of the soil from the bottom of the sod. By its use a large quantity of bulbs may be planted in a very short time, and without the least disturbance of the sward. The cup is manufactured from high-class hardened steel, and always carries a keen cutting edge. 10s. 6d. each.—BARR and SONS, 11, 12, and 13, King Street, Covent Garden, London.

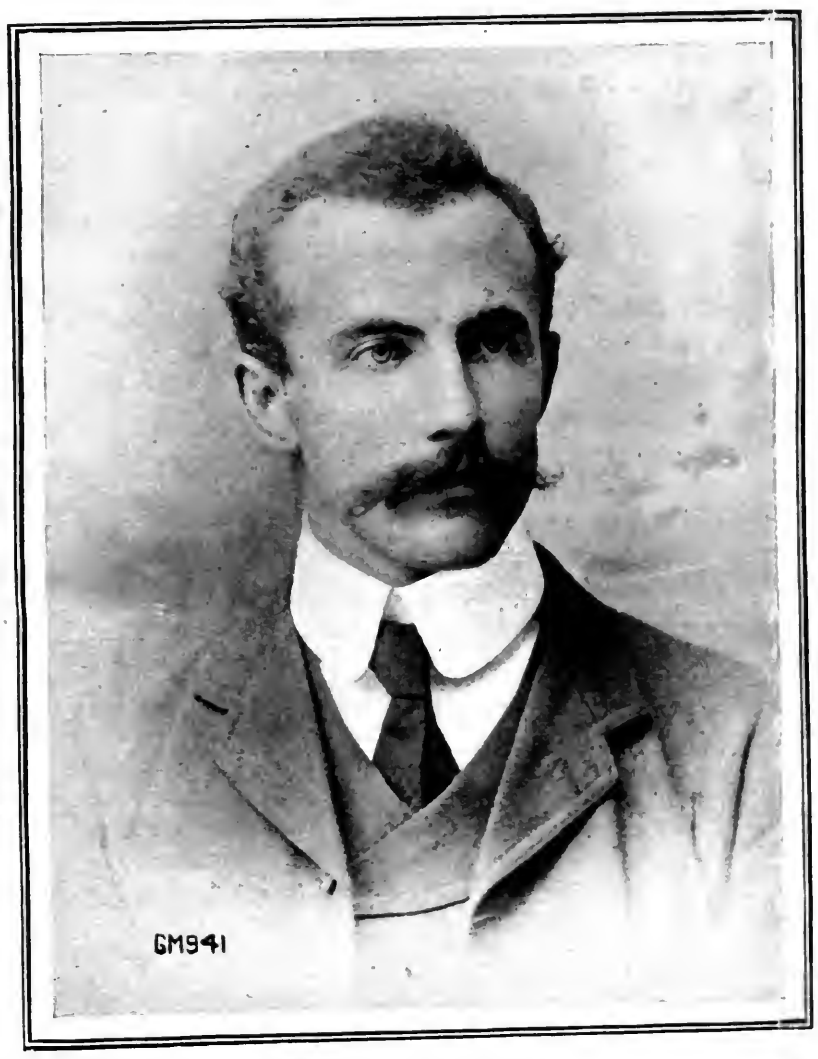
THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

The Philosophy of Trenching.

Although the work of trenching a portion of the garden does not impose a very great strain upon the mental faculties of those actively engaged in it, the operation is one that requires some knowledge of soil conditions and careful consideration to obtain the best possible results.

Trenching, simple as it may appear to those who are not well versed in cultural methods, is one of the most important of the many matters to which those engaged in garden management have to give their attention, and to some who have made considerable progress in the acquisition of horticultural knowledge it has proved a somewhat serious stumbling block. As is so well known to experienced cultivators, the chief advantages in undertaking this decidedly laborious work are the deepening of the soil for the purpose of increasing the range over which the roots of the plants can extend in search of food, and to expose the lower layers of the soil, or a portion of the subsoil, as the case may be, to the ameliorating influence of air, frost, rain, and sunshine, which are agents of first-rate importance in improving the physical condition of soils and converting the food constituents locked up within them into an available form. When the fact is fully appreciated that the beneficial bacteria exist in the largest numbers in the uppermost layer of soil, where they enjoy to the full the air and warmth essential to their activity, it is not difficult to understand how essential it is that the second, if not the third, spit of soil should be brought to the surface from time to time to give the bacteria an opportunity of converting the various constituents therein into a form in which they can be taken up by the roots and utilised by the plants in building up their structures and contributing to the utility or beauty of the garden. There is a general concurrence of opinion upon these points, and there is no great diversity in the views held with regard to the manner in which trenching operations should be carried out. Yet the results obtained from this method of soil preparation are frequently less satisfactory than could be desired, and some difference of opinion is expressed as to the relative advantages and disadvantages of this or that course of procedure. These failures and differences of opinion are largely due to the fact that no one method of trenching is equally suited to all classes of soil There are, first of all, the questions whether the soil should be trenched to a depth of two or three feet, and whether the bottom spit should, in the case of soils that have not previously been trenched, be brought straight to the surface in its raw condition. Some readers will remember the results that followed the adoption of the method that was advocated thirty or more



MR. J. JEFFREY.

years ago by some of the leaders of their day, of bringing the bottom spit to the top without dealing with it in any special manner. We may now frequently read in periodic gardening literature directions for deep trenching, without a word of qualification as to the course which should be taken when subsoil of an exceptional character is brought to the surface. The failure of the writers of the past century to qualify their directions caused much soil which had, by long cultivation and exposure, become highly favourable to plants, to be buried under ten or twelve inches of clay. When this happened the ground was distinctly unfavourable even for the most robust of garden crops, and an infinity of labour was needed to bring this upper layer to a really good tilth. There are two methods by which soils resting on heavy loam or clay, at a depth of twelve inches from the surface, may be dealt with. One is the process technically known as bastard-trenching, and in adopting this the practice is, as the top spit of each trench is taken out, to place a layer of partially decayed stable or farmyard manure, vegetable refuse, or coarse grit, in the bottom of the trench, and then fork over the soil, well mixing the additional material in the process. Under this practice the subsoil brought within the influence of the fork and accompanying fertilisers becomes so greatly improved that it may be brought to the surface without any apprehension as to the results being otherwise than beneficial. Some cultivators, and among them are several of the highest eminence, prefer, in dealing with heavy soils that have not been trenched in accordance with orthodox practice, to bring the bottom spit to the surface, and the results they obtain justify their preference. They have the aid of the several atmospheric agencies in bringing the crude soil into a condition suitable for cropping, and they are careful to take full advantage of them. By trenching the ground early in the winter it becomes sufficiently disentegrated to admit of the surface being broken down when forked over. Cultivators with experience of heavy soils who adopt this practice are careful to bear in mind that, if the addition of manure and other materials that help to lighten it are beneficial to a lower spit, or to the subsoil when in situ, it is equally beneficial when the soil is brought to the surface. Accordingly, as the winter is merging into spring, or at the beginning of the latter season, a liberal dressing of one or more of the materials suggested is given, and the soil is forked over; the fertilisers forming the dressing are incorporated with the top spit, and all the large lumps are broken down to a comparatively small state. Thus prepared the ground will be ready for cropping in the usual way, and if the crops permit the free use of the hoe during the spring and summer months, the soil will be in the best possible condition by the following autumn.

Mr. J. Jeffrey, who has served Lord Ancaster as head gardener at Drummond Castle for eight and a-half years, is coming back over the border soon to take up an important position in the horticultural world, where he will have ample scope for his abilities. Mr. Jeffrey served his apprenticeship under his father, who at that time was head gardener at Harewood House, Yorks. Afterwards he served as

journeyman, under Mr. T. Lunt, at Keir; and left Dunblane during the year Mr. Lunt won the champion grape prize at Shrewsbury. Previously Mr. Jeffrey was with Mr. W. H. Lees, at Trent Park, Barnet, when the latter was so successful with chrysanthemums; here he acted as foreman of the inside department. Then followed considerable experience in laying out gardens, notably at Ard Mulchan Castle, in Ireland, where he was in charge for two and a-half years. An insight into nursery work during eighteen months spent with Messrs. Dickson and Co., of Edinburgh, proved useful, and added to Mr. Jeffrey's knowledge of plants and methods of procedure. Mr. Jeffrey's success at Drummond Castle is an earnest of what may be confidently expected from him in the future

Definition of a Chrysanthemum Spray.—It may seem a quite small and easy matter to define what a chrysanthemum spray is, but a satisfactory definition has hitherto seemed to be beyond the cleverest experts. However, Mr. Percy Cragg, Mr. Ladds, and Mr. C. H. Curtis have formulated a definition which has been accepted whole-heartedly by the Floral and Executive Committees of the National Chrysanthemum Society, and it is as follows: "A spray is the last flowering growth, consisting of one stem with a central flower or bud, and its surrounding flowers or buds." We wonder whether everyone will accept this definition as readily as the N.C.S. Committees have done.

iris unguicularis, better known in gardens as Iris stylosa, is taking full advantage of the open weather experienced to bloom in an unusually free fashion. We have noticed its lovely flowers in many gardens where the plants have a warm position, and in the gardens at Englefield House, near Reading, Mr. A. B. Wadds, the head gardener, tells us that this variable Algerian species is quite at home at Englefield, and invariably flowers well, though in some winters the weather spoils the flowers unless they are cut in the bud state, and allowed to open indoors.

A Precocious Seedling Orchid.—A most interesting little orchid has been flowering in the orchid houses at Kew during the past few weeks. It was raised from seed sown at the Edinburgh Botanic Gardens in January, 1913, and came into bloom early in November, when it was sent to Kew. This precocious hybrid has been named Spathoglottis edinensis, and it is the result of crossing S. Fortunei, the golden-flowered species found by Fortune in Hong Kong long years ago, and S. pulchra. The latter was supposed to have been lost to cultivation. The flowers of S. edinensis have a yellow ground colour, overlaid with brown.

Cure for Streak Disease in Sweet Peas.—Through the kindness of Mr. H. A. Perkin, the National Sweet Pea Society is offering its gold medal and ten guineas to the first person who can prove to the satisfaction of the committee that he or she has found a preventative and cure for the disease of sweet peas known as "streak." As arrangements are now being made for testing preventatives or remedies, anyone who has discovered a cure should communicate at once with the secretary, Mr. H. D. Tigwell, Greenford, Middlesex, who will be pleased to furnish full particulars. Any members of the N.S.P.S. whose sweet peas have been badly attacked by streak, and who are prepared to test remedies, should communicate with the secretary at once.

The Gardeners' Magazine Almanac for 1914 is presented with this issue, and readers should see that they receive a copy. We thank those who have kindly sent dates of exhibitions and meetings, and we ask all our friends to hang the Almanac in a conspicuous position, so that it will not only set forth continually the leading horticultural fixtures of the year, but also remind everyone who consults it that on and after January 3, 1914, the GARDENERS' MAGAZINE will be issued at 1d. per week.

Old English or Florists' Tulips.—An interesting little pamphlet has reached us from Mr. W. Peters, hon. secretary of the National Tulip Society, and it will prove especially interesting to lovers of Old English Tulips, because it contains the names of all the prize-winning varieties of these flowers exhibited at Chelsea, on May 21 and 22; at Middleton, on May 31; and at Wakefield, on June 2. The society's London show in 1914 will be held at the Royal Horticultural Hall, Westminster, on May 20 and 21, at Chelsea.

National Chrysanthemum Society's Exhibitions and Meetings in 1914.—The annual meeting of the Society will be held on Monday, February 2, 1914; and the exhibition dates for next year are October 7 and 8, and November 4, 5, and 6. The Executive Committee will meet on September 21, October 19, November 23, December 14, and January 18 (1915); while the meetings of the Floral Committee will be on September 21, October 7, 19, and 20, November 4, 16, and 30, and December 9.

Crystal Palace for the Nation.—It is with very great pleasure we learn that at last the Crystal Palace has been secured for the nation, in spite of defections on the part of those who promised to contribute towards the purchase price. To Sir David Burnett, ex-Lord Mayor of London, thanks are due for the splendid effort he made to preserve the Crystal Palace from the speculative builder, but even greater thanks are due to the Earl of Plymouth, who so patriotically purchased the Palace gardens for £230,000, and offered them to the nation for the same price. Chiefly because Camberwell and Penge failed to respond adequately, the public appeal for funds closed with a deficit of £29,000, and the Earl of Plymouth has saved the situation by agreeing to hand over the property for about £30,000 less than he gave for it. Our readers will remember that the Earl of Plymouth is a great gardener, and has fine estates at St. Fagans and Hewell Grange, and he is the president of the British Gardeners' Association.

Trials of Roses at Bagatelle.—As in previous seasons, so in 1914-15, a trial of roses will be held in the Rosery at Bagatelle, Neuilly-sur-Seine, France. The trial is for new roses, and in every case the name of the raiser must accompany the plants sent. So far as possible the plants should be in pots, and not fewer than five specimens of each variety should be sent by April 15, 1914. Planting will take place directly after this date, and the roses will remain in the Bagatelle gardens until October, 1915, so that the special jury selected may have opportunities of studying the habit and flowering qualities of the roses during two seasons. Those raisers who propose to take part in these trials should communicate with the Curator, Roseraie de Bagatelle, as above.

Saturday Half-holiday at Hawick Nurseries.—We learn with pleasure that Messrs. John Forbes, Lim., of Hawick, have granted their employees an extra hour's leave on Saturdays. Hitherto, the Saturday half-holiday has commenced at two o'clock, but from now onwards the men will cease work at one o'clock.

Greenhouse Plants in Flower at Kew.—Few gardeners fully understand how large a number of flowering plants are available for the decoration of the conservatory at Christmas time, but if they visited the Greenhouse (No. 4) at Kew during that season their ideas would be considerably enlarged. When visiting the Kew conservatory a few days ago we noticed the following blue flowers in bloom: Eranthemum pulchellum, Statice brassicæfolia, and Pycnostachys Dawei—the latter most effective, and represented by plants 4ft. to 8ft. in height. Browallia viscosa and Coleus thyrsoideus were represented by good batches. Among the white flowers were Begonia Gloire de Lorraine var. Turnford Hall, Chrysanthemum anmethifolium, with Cannell's White, and good plants of the sweetly-scented Buddleia asiatica. Red flowers included the winter-flowering Begonia Winter Cheer; Bouvardia President Cleveland, Euphorbia pulcherrima (poinsettias), Centropogon lucyanus, and some fine examples of Plumbago rosea superba. The pink flowers we noticed included Begonia semperflorens var. Prima Donna, and the ever-useful B. Gloire de Lorraine, with the old Rhododendron Taylori. Other subjects which added to the pleasing effect were perpetual carnations in variety, a good selection of Cyclamen persicum, azaleas, heaths, Impatiens Oliveri, and I. hybrida, pelargoniums, and Peristrophe speciosum, which was freely displaying its magenta-purple flowers. Calceolaria Burbidgei added a touch of bright yellow, while Solanum capsicastrum var. Melvillei, with an abundance of berries, added scarlet to the other attractive colours.

Horticultural Exhibitions and Conferences at the Anglo-American Exposition in 1914.—Arrangements have been made for the following series of exhibitions and conferences to be held at the White City, Shepherd's Bush, London, W., in 1914: Perpetual Carnations, May 27; Hardy Plants, June 10; Roses, June 23; Sweet Peas and Border Carnations, July 8; Forestry, July 15; Dahlias and Gladioli, September 2; and Fruits, October 1. The societies specially interested in these several subjects indicated are co-operating with the Horticultural and Arboricultural Committee, to make these exhibitions and conferences a success, and the Royal Horticultural Society is interesting itself in the project.

Proposal for a New Sweet Pea Society.—Miss Hemus considers the National Sweet Pea Society "a discredited Society," and in her catalogue she puts her case against that body as follows: (a) The constitution of the Society gives a voice only to members who attend the annual meetings. (b) Traders attend the meetings, and thus dominate the Society; amateurs have become apathetic, and their interests are therefore ignored. (c) Through lack of confidence, the annual "trials" of alleged new varieties are not fully representative, and the awards are no indication of what is newest and best. (d) The Society does nothing to deal with the question of multiplication of names, nor could it as at present constituted, because it cannot claim to possess disinterested government. Other

remarks follow, and Miss Hemus concludes that, "since there is no postal vote, and no possibility of real reform in the present Society, it is necessary to form a new one, and I venture to propose this, and also to give the following idea of what would seem to be the objects most worthy of its activity; (a) To grow every alleged variety in existence, and reduce the list to a comparatively short one. (b) Thereafter yearly to grow all approved varieties against new challengers. (c) To dominate nomenclature." An annual subscription of 3s. 6d. per annum is suggested.

A Fine Chestnut Orchard.—Little heed is paid to the Sweet Chestnut in this country except as an ornamental tree, but quantities of nuts are imported each year from France, where chestnuts are planted in orchards. In the United States the Sweet Chestnut is very popular, and considerable attention has been paid to its improvement as an orchard fruit. At Lewisburg, Pa., one grower has over 400 acres under the Paragon Chestnut, containing about 50,000 trees, from six to fourteen years old, and all in bearing. An eleven-year-old tree will carry a bushel of nuts. As an indication of the interest taken in sweet chestnuts we may add that this same grower has 300,000 grafted trees ready for the market, and above a million seedling stocks for grafting.

How Sweet Peas Set Fashions in Colour.—Sweet peas are answerable for many things, and now we learn that Mons. Rodier, of Paris, has had quantities of dress fabrics dyed in shades of colours found in sweet peas for ladies' wear next summer. He grew a large number of varieties of this popular annual, and then submitted blooms to his dyer, who in turn reproduced the colours in dress materials. Artificial sweet peas for use in millinery are very popular, and sweet peas enter largely into the designs of wall-papers, etc., nowadays, so this further advance is not unexpected.

A Splendid Crop of Potatoes.—It is reported that 725 bushels of potatoes have been lifted from one acre of ground at Cape Breton, Nova Scotia, on the farm of a Mr. R. Wilson, who went to that country from Scotland a few years ago. At first he worked as a miner, but seeing the great possibilities the Cape Breton soil offered, and the splendid market right at hand, he bought a farm, and although for several years it had been devoid of proper care and required much labour to bring it up to a Britisher's standard, this potato yield proves he has accomplished his purpose in a remarkable degree.

The Largest Apple, like the big gooseberry and the tallest sunflower, seems to be a source of never-ending interest. Not long since Covent Garden was startled by a Gloria Mundi apple weighing 32½oz., but this is "beaten to a frazzle," as our American friends say, by an example of Spokane Beauty, orchard grown, and weighing 38oz. This monster is vouched for by Mr. J. T. Bealby, of Nelson, British Columbia, and was exhibited at Vancouver on the occasion of the first Canadian National Apple Show, in 1910. It was weighed in the presence of the Deputy Minister of Agriculture for British Columbia, so we cannot dispute the figures, and must, for the moment, hide our diminished heads until someone comes forward with a 40oz. specimen.

Small Holdings in Park Lane.—The favourite thoroughfare along the east side of Hyde Park, London, is by no means straight, and the frontage of the houses is very irregular. Sir Laurence Gomme states that this irregularity is due to the fact that long years ago a large number of narrow, acre strips of land were devoted to agriculture in the neighbourhood, and as the ends of these small holdings came out into Park Lane, the present zig-zag appearance of the frontage line resulted.

ROBINIA PSEUDACACIA DECAISNEANA.

Among the numerous varietal forms of the False Acacia, or Common Locust Tree, Robinia pseudacacia, Decaisne's robinia, is one of the most distinct and valuable. It differs from the type in having rosy-pink flowers, which are at their best in June, a month later than the familiar white-flowered False Acacia, and it has fewer spines. Though not common in our gardens, R. p. Decaisneana is a fairly old

ROBINIA PSEUDACACIA DECAISNEANA.

variety, and was figured in the "Revue Horticole" for 1863. The tree is free in growth, and, in common with other robinias, thrives in sandy, comparatively poor and dry soils. In addition to its value for park and pleasure-ground planting, it is a suitable tree for street planting. A specimen growing in the Kew Road, Richmond, is the object of considerable attention when in flower, with its tender green leaves, and pendulous racemes of dainty, rosy-pink flowers—a striking contrast to the elms, London planes, etc., close by.

Decaisne's robinia may be raised from seeds, a fair number coming true, with, occasionally, a tree with darker-coloured flowers, to which the name of rubra has been given. The seeds should be sown as soon as mature, otherwise germination is very irregular. To save time, in nurseries, grafting on the common robinia is the more generally favoured method of propagation.

A. O. K.

THE SHRUBBY VERONICAS.

Although the shrubby veronicas are not sufficiently hardy for general outdoor culture in the British Isles, they are invaluable for certain positions, notably in the southern and western counties of England, the West of Scotland, Ireland, and the various islands about the coast. They revel in sea air, and in many parts of the south-west may be seen flourishing on cliffs and walls within a few feet of high water and exposed to violent winds. On the Kent and Essex coasts likewise they may often be noticed in good condition; while in North Wales, the Isle of Man, and the West of Scotland they form large bushes, and are sometimes even used for hedges. In those parts of the country where little frost is experienced some of the species may be found in flower at almost any period between June and March, and for a space of from four to six weeks many of them are masses of bloom.

They are not difficult to cultivate, for they form fine, shapely examples in ordinary garden soil, and require little pruning, save pinching the points of the shoots out a few times while the plants are young. The old flower-heads become unsightly, however, in some instances, and for appearance sake they should be removed. Propagation may be effected by means of cuttings during spring and summer.

Most of the shrubby species are natives of New Zealand alone. A few, however, extend to Tasmania, and one, V. elliptica, is said to occur in New Zealand, the Falkland Island, Tierra del Fuego, and S. Chili. They vary considerably in habit, some forming large, dense bushes, five or six feet high, and more across; others compact, cushion-like masses, scarcely a foot high; some are like a tiny, prostrate-growing cypress; and one or two species, in their native country, are reported to grow into small trees twenty feet or more in height, with trunks up to a foot in diameter.

There are many uses to which the shrubby veronicas may be put. The dwarf, low-growing kinds are excellent for planting on rockwork, and for placing in groups about the margins of lawns. Those of medium strength are suitable for the front of a shrubbery, in specimen beds, or planted on stone and earth fences, such as are found in the south-west counties, while the most vigorous kinds grow into excellent specimen plants, and are well adapted for use as informal hedges. Should these veronicas show signs of deterioration at any time, it is usual to destroy them, and commence again with young plants, for the latter will form good specimens more quickly than a plant out of health will resume its lost vigour.

In the vicinity of London and other large towns it is usual to grow some of the more vigorous and free-flowering kinds in pots for window-boxes and house decoration, examples in five or six-inch pots being available at about sixpence each.

Of the vigorous-growing kinds, the following are worth special attention: V. speciosa is perhaps the commonest of all. It grows from three to six feet high, and forms a dense bush from three to eight feet in diameter. The dark green, oblong leaves are two and a half to four inches long, and the inflorescences appear from their axils during autumn and winter. The purple flowers are in dense racemes, three to four inches long, but there are numerous garden varieties which bear larger inflorescences of red, pink, white, lilac, or purple flowers. Good varieties are: Autumn Glory, deep blue; Blue Gem, blue; Gauntletti, salmon-pink; Eclatante, red; Etoile Blanche, white; La Séduisante, reddish-purple; Madame Chretien, purple; and Purple Queen, purple.

V. salicifolia is usually met with as a bush three to five feet high, but on the higher ground in New Zealand it sometimes forms a small tree twenty feet high, with a trunk twelve inches in diameter. The leaves are more or less lance-shaped, and three to five inches long. The white flowers are borne in pendulous racemes, which are often from five to seven inches long, although specimens have been observed in New Zealand with inflorescences twelve inches in length.

Another very showy kind is V. parviflora. Mr. Kirk, in "The Forest Flora of New Zealand," mentions this as sometimes attaining a height of twenty-five feet. Here, however, it is familiar as a bush two to four feet high, with linear leaves one and a half to two inches long, and branched inflorescences three to five inches long, of small white flowers, which mature during late summer and autumn. V. angustifolia grows into a shapely bush two to three feet high. It is recognised by its linear leaves, which are one and a half to three inches long, and by its racemes of white flowers with reddish stamens, which are at their best during late autumn and early winter.

V. macrocarpa has oblong leaves two to two and a half inches long and one-half to three-quarters of an inch wide, and dense racemes, three to five inches long, of lilac flowers borne in winter. It grows at least four feet high. V. carnea is another showy autumn and winter-flowering species. It attains a height of three to four feet, bears linear leaves three to four inches long, and produces a profusion of long racemes of reddish flowers. V. Derwentia forms an erect bush four feet high, and bears pale blue, or sometimes almost white, flowers in long racemes.

Of dwarfer-growing species and varieties the following are of special merit: V. Darwiniana, a compact bush with small, glaucous leaves scarcely half an inch long; V. Godefroyana, a low-growing, spreading bush, with small glaucous leaves; V. anomala, an erect bush, with tiny, green, ovate leaves and white flowers; V. pinguifolia, a dense, compact bush, one foot or so high, with grey-green leaves scarcely half an inch long, and white flowers; V. obovata, also a dense bush, with grey-green, obovate leaves; V. pimeleoides, a rather loose-growing bush, with small, glaucous leaves and purplish flowers, and V. diosmifolia, a graceful plant, with small, linear leaves and white flowers.

There is another set which differs from the rest by reason of their exceedingly small leaves. Representatives are V. cupressoides, with cypress-like growths, very minute leaves, and pale purple flowers; V. epacridea, and V. Armstrongi. They are well fitted for rockery planting.

Two species which stand out distinctly among others are V. Hulkeana and V. Traversi; the former is one of the tenderest species, and the latter the hardiest of all. V. Hulkeana is a rather loose-habited shrub, with elliptical, serrate leaves, one to one and a-half inches long. It produces very large panicles of pale lilac flowers during spring, and is excellent for growing in pots for greenhouse decoration, or for planting at the foot of a wall in the milder counties. V. Traversi, on the other hand, forms a dense bush four feet high and as much across, with small, green, ovate leaves, and it bears a profusion of white or lilac-tinted flowers in short, dense racemes in June. It may be grown in most parts of the country, excepting the extreme north.

Kew. W. DALLIMORE.

KNIPHOFIAS.

To define fully the use and value of the torch lilies requires an abler pen than mine, but a few suggestions as to suitable planting sites may be of service. For terrace planting they are superb, and when set in beds in turf, with the grey stone walls of an old mansion as a background for them, they are fine. Equally fine is the result of bold extended plantings arranged on both sides of a broad pathway of grey stone. In such a scene, with the many varieties bringing their shades of scarlet, orange, flame, gold, yellow, amber, apricot, salmon, etc., the picture at flowering time is almost beyond description, especially on sunlit days in late summer.

Such gems as K. John Benary, K. Beacon, K. R. Wilson Ker, etc., on the summit of a bold rock garden are splendid. I may be criticised for this suggestion, but if the depth and quality of the soil are right I have no fear for the Kniphofias. Mass them there, with the accompaniment of a few groupings of Yuccas, or a few masses of Sedum spectabile at their feet, and then watch the effect in summer. Mark that blazing summit at blossom time! Aye, and if you can repeat the same effect upon other and more distant ridges or points of vantage you have gained a glory of colouring and effect unexcelled by any other garden planting.

And this is not all. A lakeside planting above the water margin, bold and free, so that the host of torches may be mirrored in the clear, silent water, gives a doubled beauty that can be heartily commended.

Planting and division is best done in early autumn, thus allowing the formation of fresh roots before the winter is upon us. I have also occasionally transplanted in spring, but this plan, which may be good in uncongenial districts, entails a deal of suffering to the plants if the weather continues dry, unless, of course, one has the time to keep the plants watered when necessary. The fact that staking is not necessary with the torch lilies is another great recommendation in their favour, as many perennial plants lose half their beauty through the necessity of staking.

I may be permitted to mention just a few kinds, omitting the small species and varieties, which will be dealt with separately later. The tall forms, and those of medium height, will serve in the ways I have noted, and I trust the selection will meet with general approval. It is as follows:

K. R. Wilson Ker, a strong-growing plant, with massive torches of glowing coral scarlet; K. John Benary, a glorious deep scarlet of medium height, and grand appearance; K. Excelsa, a tall striking variety, with crimson and orange colourings; K. Egypt, tall, rich amber, a fine form; K. Leda, an exquisite coral-red and orange variety, of pleasing appearance; K. pyramidalis, a very stately gem, of a pale yellow colour; K. Lemon Queen, a seedling from K. citrina, and a general favourite; it is a pure soft yellow; K. Golconda, a pleasing apricot shade; and K. Beacon, a glowing red, coloured amber below, a very attractive form.

Also worthy of note are K. caulescens, an immense early-flowering red and yellow kind; K. foliosa, also early, a rich scarlet and yellow; K. Tucki, another early one, brick-red and primrose-yellow; the fine forms of K. uvaria, scarlet and orange; K. grandiflora, orange-red and yellow; and K. nobilis, a rich orange-red, of grand size and appearance.

EAST COAST.

EVERGREEN SCROLLS AND MONOGRAMS.

The sixteenth century saw the art of the topiarist attain its zenith; in the seventeenth century it was still in favour, but after this it steadily declined before the claims of a less artificial system, eventually giving place to the informal or natural gardening so prevalent to-day. It is an exotic art, whose severe and austere formality found an echo in much of the life and architecture of the period in which it flourished. To its advocates and votaries alone can its misfortunes be attributed, for an excessive and extravagant use of the art frequently brought it into ridicule.

Topiary may often be introduced with good results, possibly only in the form of a border or scroll, with simple forms clipped, and giving emphasis or directness to the scheme. As illustrating the extreme limit to which this art attained I may cite the examples at Elvaston, in Derbyshire, and Levens Hall, in Westmoreland. These are, however, the work of past decades; I am able, nevertheless, to reproduce an example that is essentially modern, highly original in its conception, and that illustrates the higher art of the topiarist. The view is in the gardens of Nuneham Park, in Oxfordshire, the residence of the Right Hon. L. Harcourt, and shows the Harcourt monogram and crest clipped in shrubs that are evergreen.

Box, yew, and, less frequently, holly, are employed for work of this nature; they are naturally of slow growth, and live to a great age, while they bear with impunity the constant clipping and pinching necessary to retain the desired form. Where a simple outline is wanted, as in border or scroll, the normal green will usually give the best effect, particularly if it comes into close proximity with other colours. Where, however, an intricate design has to be executed, then, by the addition of the variegated forms, practically any pattern may be reproduced.

Yew has some advantages in that it is more serviceable, while the small foliage does not exhibit the mutilation wrought by the workman's shears in so violent a manner as holly; the latter offers a wider range in the development of the art, as not only in colour, but the form of the leaves, exhibit great variation.

Where work of a diminutive or perfectly flat character has to be reproduced the dwarf form of box, usually employed as edging, has much to recommend it. Other plants that may be introduced with it, as contrasting colours in an intricate scheme, are Santolina incana, Veronica buxifolia and V. carnosula, the various coloured forms of shrubby thymes, and also the dwarf forms of erica. THOMAS SMITH.

Coombe Court Gardens.

SCROLL-WORK, MONOGRAM, AND CREST AT NUNEHAM PARK, COMPOSED OF EVERGREEN SHRUBS.

COLLETIA CRUCIATA.

This Colletia, which, in some places, is just now flowering, is in every way a strange shrub, which cannot be confounded with any other. It is practically leafless, the entire specimen being, as it were, built up of large, thick, flattened triangular-shaped spines, arranged in pairs, each pair being set crosswise to the next. The spines are of a deep green tint, and the flowers, borne in little clusters from the lower part of these spines, are small and urn-shaped. They are of a greenish-white colour and wax-like texture, and scarcely noticeable unless the bush be closely inspected.

C. cruciata is a native of Uruguay, and is sometimes known by the specific title of C. bictonensis, but C. cruciata is a particularly descriptive name. There is another colletia, known as C. horrida or C. spinosa, which is simply a mass of stout, awl-shaped spines. This plant, though widely removed from C. cruciata in general appearance, was long regarded as a distinct species, but many instances have occurred of shoots of one kind being produced from specimens of the other, thus proving it to be a very remarkable case of dimorphism.

All the Colletias are quite hardy in the South of England, but scarcely so in the colder districts. Despite their unpromising appearance they are not difficult to strike from cuttings, if these are taken in the summer, inserted in sandy soil, and kept in a close frame until rooted. S. W.

THE BEST HONEYSUCKLES.

The observant person, ignorant alike of botanical establishments and of gardening encyclopædias, who spent his leisure in visiting our English gardens, might well be excused if he arrived at the conclusion that there were only two distinct honeysuckles worth growing, for during his perambulations he would rarely meet with more. These are our native Lonicera Periclymenum and the form of the Japanese L. japonica, with yellow-spotted leaves, two very charming and valuable climbers; but there are others—many others.

LONICERA PERICLYMENUM.

Altogether there are well over one hundred species and varieties of Lonicera, and, in addition, a goodly number of hybrids have been raised on the Continent, but, curiously enough, chiefly between species which one would not include in a list of the twenty best honeysuckles. The inference is that new, rather than improved, forms were aimed at. The honeysuckle hybridist who can give us a really good bush Lonicera, which has the fragrance of L. Periclymenum or L. fragrantissima, would earn the lifelong gratitude of many thousands of gardeners and, incidentally, much money.

Lonicera nitida, one of the newest bush honeysuckles, has the virtue of fragrance, and it makes a fairly good shrub of medium size, but the creamy-white flowers are not borne in sufficient quantity to make it the ideal bush species, and the colour is cold. L. tatarica and L. tibetica, both of which have rosy-coloured flowers (and the latter are very fragrant), are of bushy habit, and probably have great potential value. L. pileata, a dwarf spreading evergreen, is useful in the rock garden, a place where several of the best deciduous sorts should be planted.

But nearly all the true bush honeysuckles are singularly deficient in fragrance. The best, from a cultural point of view, L. Maacki, a comparatively recent introduction from China, does not appeal to me, and I have always regretted having been beguiled by the R.H.S. Award of Merit into purchasing it. My disappointment was great, and I should have done better had I obtained a L. sempervirens to train against the warmest wall of the dwelling-house. The latter North American species, and its variety minor, are not quite hardy enough for outdoor planting, but make charming cool greenhouse rafter plants, when, during the spring and summer—and often again, in a lesser degree, towards the end of the autumn—the scarlet and yellow flowers are delightful. The type will pass safely through a very hard winter when trained against a really warm wall.

L. Standishi and L. fragrantissima are even more valuable than the last in such a position. Under this condition their flowering period is lengthened, and the fragrance is intensified. Even when grown in the conventional manner these two honeysuckles are exceedingly valuable, for not only do they flower at a time when few hardy flowering shrubs are blooming, but the number which bear fragrant blooms in February, or often earlier in the year, is notably small. These early-flowering honeysuckles must not be pruned when the others are receiving attention; unless the work is delayed until after the flowering season is past there will be very little bloom.

The best of the summer-flowering honeysuckles is our native species, with the Dutch and late Dutch varieties. The flowering period varies with the season. If June and July should be hot and dry this is approximately the limit of blossoming, but in a moist year the flowering is prolonged into August, and often till the middle of September. Personally, I do not think that the longer period compensates for the loss of the almost startling fragrance of the hotter years. Who has not memories of a dusty hedgerow on a blazing midsummer's day when from the limp and apparently lifeless yellow-tinted flowers of the honeysuckle came wafts of the most delicious perfume? This native species is no plant for the trim gardener; it is not for one who has a place for every plant, and whose shrubbery is composed of severe specimens, each occupying its allotted space and no more. To derive the greatest enjoyment from it the twining growths must be subjected to no severe discipline, but, like the Drakes and Raleighs of the "good old days," be given leave to go off on a roving commission and take possession, often kindly enough, of whatever they happen upon. Then will it give plenteously of its grace and fragrance; but crab it and confine it, and it sulks. It is for this reason, because it is really a wild creature and cannot be ever thoroughly tamed, that the standard-trained efforts of the Continental nurserymen are so unsatisfactory.

The Goat's-leaf Honeysuckle (L. caprifolium) has so long been naturalised that we may almost look upon it as being a native. It has certain features in common with L. Periclymenum, but the deeper yellowish flowers have bluish tubes, the stems twine from left to right, and it flowers earlier than the true native species, but is equally fragrant. The Japanese L. japonica flexuosa is as fragrant as any honeysuckle, but its yellow flowers are comparatively few. The paler yellow L. flava, from North America, is another exceedingly fragrant species.

Although we find an occasional example out of doors in Cornwall, the largest-flowered species, L. Hildebrandiana, is decidedly tender, and must be grown in a greenhouse. The flowers are four to six inches long, and, opening nearly white, soon become golden-yellow in colour, and on exposure to strong sun change to orange-crimson. The leaves are correspondingly large, and of a rich green.

CECIL AUBREY.

EUPATORIUM WEINMANNIANUM.

Residents in the particularly favoured parts of these islands regard this Eupatorium as a valuable outdoor shrub, as its blossoms are produced during the autumn and early winter months. Where the winters are too severe for it to be looked upon as an outdoor plant it forms a very attractive feature in the greenhouse or conservatory, because, when at its best, it is a mass of clusters of white, sweet-scented blossoms. There are other Eupatoriums well worth cultivation, but E. Weinmannianum and the looser-growing E. reparium are the first to bloom. Of those that flower early in the New Year, I may mention the blush-tinted E. petiolare, and the sturdy-growing, white-flowered E. vernale. In the spring E. ianthinum, with lilac-coloured heads of blossoms, is at its best.—W. T.

THE CHRISTMAS DESSERT TABLE.

A plentiful supply of fruit is certainly a most pleasing feature of the Christmas season, and especially so if it be home grown. There is something in the flavour of British grapes that cannot be equalled by grapes from any other country, and, in the same way, home-grown Cox's Orange Pippin apples have a flavour not found in the same variety grown in any other country—Tasmania, for example.

The gardener or amateur who can provide a full Christmas dessert of the kind and character I suggest has reason to be proud of his achievement, especially if he arranges the fruits in an attractive manner.

Grapes are, without a doubt, the most important fruits for use and display. Among white grapes none can compare with Muscat of Alexandria and Canon Hall muscat. When the latter is well grown it is to be preferred to the former on account of the extra size of the berries, which are straw-yellow in colour, with firm flesh, and of a rich muscat flavour. The Alexandrian muscat, when the berries are of that rich amber tint of colour so pleasing to look at and free from shrivelling, is difficult to excel either in appearance or in flavour. Among black grapes none can equal perfect examples of Mrs. Pince, as, when richly coloured, the desirable flavour of this grape is well brought out. Showy grapes, introduced chiefly to give effect, will include Gros Colmar, Gros Maroc, and Alicante. The two former have huge berries, while all three are generally flushed with a dense bloom that is very attractive.

Pears come next in importance to grapes on the dessert table, and while flavour and quality is the aim, rather than appearance, I cannot do better than recommend Glou Morceau, Winter Nelis, Josephine de Malines, and Hacon's Incomparable.

Apples are homely fruits, and when of fine flavour are much appreciated. Cox's Orange Pippin has no superior in flavour, and when well coloured is most attractive. Some persons think no apple is equal to Ribston Pippin, yet I fear in this case much sentiment has to be imported into the declaration. Anyhow, it is a good, old-fashioned English apple, which we cannot afford to lose. Blenheim Orange, although in many instances past its best, may, from some soils and when specially kept, be available. Apples are often needed to give colour, and in this respect Gascoyne's Scarlet, with its brilliancy and size, can be used with great effect.

Among smaller fruits, but which cannot be omitted, we have Kentish Cob nuts, filberts, and walnuts. Royal Medlars should not be omitted, as many people have a weakness for their peculiar flavour.

To secure the finest display possible, and to further increase the variety of fruits, we must include imported pineapples, Canary bananas, Jaffa oranges, and almonds. Where foreign apples are a necessity the best varieties at Christmas-time, having regard to quality as well as appearance, are King of Tompkin's County, Newtown Pippin, Banana Apple, and Grime's Golden Pippin. The latter is a remarkable apple of fine golden colour and rich flavour; indeed, it runs the best of our home-grown apples closely for quality.

The arrangement of the fruits is important, and as a rule china receptacles are used of many shapes and sizes. In the case of grapes, tall stands, on which two bunches of one variety can be displayed, produce a fine effect. Pears and apples should be liberally used, and dishes should contain a dozen handsome fruits. To fill up the spaces on the table, smaller dishes of apples and oranges may be employed to brighten up the duller hues of nuts, medlars, or Josephine de Malines pears.

The decorations for the fruit dishes need consideration, and must, in some degree, be governed by the general colour of the room, the lighting arrangements, and the colours of the lamps and shades. Vine leaves, from such varieties as Gros Guillaume or Alicante, with tints of red and yellow, harmonise with all fruits, except, perhaps, the brightest apples. In the latter case the yellow-tinted leaves only should be employed. Where vine-leaves cannot be obtained the coloured foliage of Berberis aquifolium is quite good; and if something more sombre is needed for bright apples, then Portugal laurel may be used. Sprays of golden privet add bits of colour to green pears. Holly sprays, both variegated and green, with berries attached, can be deftly introduced to give a seasonable effect.

E. MOLYNEUX, V.M.H.

Swanmore Park.

WINTER SPRAYING.

Many of the insect pests that attack fruit trees are accustomed to hibernate in the imago state during the winter months. It is necessary, of course, that they should find some suitable shelter for this period of resting; heavy lichens provide this shelter in a most admirable form, and the moss and algæ which also infest the trees to a large extent in the winter months, especially in damp, low-lying situations, offer similar shelters to these hibernating insects. To destroy the pests the first step therefore should be to remove the protective medium in which they rest throughout the winter, and for that purpose suitable winter washes should be employed.

Caustic washes are generally recommended for clearing away all moss, lichens, and insect life in winter, but a considerable amount of care should be exercised in preparing such washes. Gardeners are not, as a rule, experts in chemistry, and so many go wrong in mixing various materials that react upon each other, to produce a compound which could be obtained anywhere for about half the cost. Like the manuring of farm crops, one needs to wash fruit trees in winter "with brains"; the mixing and application of winter washes should be put on a scientific basis.

Crude potash, or pearlash, potassium chloride, saltpetre, or crude sulphate of potash, as it is variously called, is generally recommended as an ingredient in winter washes, together with a similar proportion of caustic soda, and a certain quantity of water; but in the majority of cases this crude material contains a great many impurities, and also an excess of carbonic acid in the form of bicarbonate. The caustic soda, when mixed with it, quickly reacts with this carbonic acid, and forms compounds which are of practically no use at all, so far as the original purpose of the wash is concerned.

Undoubtedly it is better to use a simple caustic wash, and one that may be recommended for this purpose is prepared by dissolving 1lb. of 98 per cent. caustic soda in twenty gallons of water. This wash will prove to be particularly effective, and, if need be, 1lb. of common washing soda may be added to the twenty gallons of caustic soda solution, although this is not by any means always necessary or advisable. The fact is, continual spraying with a caustic wash tends to injure the bark of fruit trees to some extent, and, consequently, the health of the tree itself may be impaired. One may obviate this undesirable effect, however, by spraying with an iron solution a few hours after giving the caustic wash. The former is useful as a fungicide, and negatives any injurious effects that may be caused by the caustic wash. It may be prepared by dissolving 1lb. of sulphate of iron in ten gallons of water, and adding 1oz. of sulphuric acid.

As regards the best time at which to apply these winter washes, a great deal, of course, depends upon the size of the plantation; where some thousands of trees are grown, for instance, an early start must necessarily be made, although the majority of small growers are accustomed to leave the work until just before the opening of the bud. At the same time, however, it is probable that better effects would be secured by earlier spraying, especially for the destruction of the eggs of such pests as Psylla Mali in apples, since these eggs will not have had time to become thoroughly hardened in their shell.

Besides the ordinary caustic wash there are many well-known proprietary washes on the market that have earned no little recommendation from experts. A properly made lime-sulphur wash is no doubt exceedingly effective, for, judging by the ingredients in it, it should certainly have some corrosive action on the shells of eggs deposited on the bark, in autumn, by oviparous females of the aphis, and also on the egg shells of the minute psylla ova. And here again is another strong argument in favour of early winter spraying. In all cases prevention is better than cure, and if these oviparous females can be destroyed early in the winter, and so prevented from depositing their eggs, a great deal of trouble and subsequent labour will be saved in spring.

Pickering's formula for a winter wash is one that has been very strongly recommended by practical horticulturists. It is composed of the following ingredients: Sulphate of iron, 1lb.; lime, ¼lb.; caustic soda, 2lb.; paraffin (solar distillate), 5 pints; and water to make ten gallons. The sulphate of iron is dissolved in about nine gallons of water; the lime is then slaked in a little water, and a little more water is next added to make a "milk." After running this milk into the iron sulphate solution the paraffin is churned into the mixture, and the powdered caustic soda is added to the whole just before the wash is required for use. There has also been considerable experiment with a lime and salt wash for winter use, the expected effect being that the eggs may be coated so that they will not hatch.

Lime spraying is also practised by some growers as a winter dressing, the great advantage here being that the lime—which is applied hot—has considerable cleansing powers and a certain amount of corrosive effect on the eggs of insects. Scale insects can be cleared from fruit trees by lime spraying, and the fluid that falls to the ground is likewise useful in supplying the trees with carbonate of lime; from 5 cwt. to 2 tons of lime per acre are required for efficient spraying, so that there may be quite a considerable amount of carbonate of lime available in this way. The best material to use is Buxton lime, and it should be ground as finely as possible. This lime wash should be applied at a temperature of not less than 100 degrees F.; the fresh lump lime should be slaked with hot water for this purpose.

Old Basing.

THE CHARM OF WINTER.

"When icicles hang by the wall,
And Dick the shepherd blows his nail,
And Tom bears logs into the hall,
And milk comes frozen home in pail."
"LOVE'S LABOUR'S LOST."

When people speak of the delights of winter they are generally thinking of winter sports, shooting, dancing, or the like, but to refer to them in a journal mainly given up to gardening—generally regarded as a more or less fair-weather occupation—will seem a little incongruous, though not to those who, like Wordsworth, have learned to look on Nature as though they loved her. A much-travelled and literary man, writing in one of the London dailies some time ago, said that the climate of this country was as good as any during six months of the year, and better than any the other six. It is a truism that it is to the changefulness, or, as some call it, the fickleness, of the English seasons that so much of their charm is due.

Do people ever reflect what a monotonous time it would be, and what an amount of enjoyment we who love the country would lose, if we were to have perpetual summer? The late Lord Dufferin, in his "Letters from High Latitudes," tells us of the tragedy of a cock which they took on board at Stornaway on their voyage north. As the nights became shorter and shorter it seemed to get bewildered by the phenomena of dawn and sunset being continuous, and when both entirely ceased it almost gave up crowing, and became more and more melancholy, finally jumping overboard and drowning. We do not realise how great an element change is in our happiness, and, glorious though the summer days are, no one wishes them to be longer, or would like the night to disappear altogether, so that we should lose the beauty and the magic of the summer sunset, though few of us ever see the no less beautiful sunrise at that season.

Many began to tire of the long summer of 1911, and even flowers may last so long in beauty that we almost cease to appreciate them. We should take little pleasure in a bed of Paul Crampel pelargonium after a continuous blaze for a twelvemonth. As Ruskin says: "The character of everything is best manifest by contrast. Rest can only be enjoyed after labour; sound, to be heard clearly, must rise out of silence; light is exhibited by darkness, darkness by light; and so on in all things.

As age increases we learn, or should learn, how to live and to get more enjoyment out of the world around us, though it was quite a middle-aged man whom I once heard remark that in this climate there were only two months of summer and the rest was winter. He was old enough to have learned that every season offers us special charms, and winter is by no means an exception, even to the gardener. No part of the latter's reflections in the winter need be given up to longings for the spring and summer, but if he is wise he will accept the enjoyments that offer, and when he realises how many they are, he may be able to say:

"At Christmas I no more desire a rose
Than wish snow in May's new-fangled mirth;
But like each thing that in season grows."

Winter gives him a breathing space, a little more time for rest, study and reflection, to fit him better for his work another year. It is a very brief pause, and only really exists in its fulness during a week or two of severe weather, and even then there are plenty of indoor matters to see to in connection with his hobby or business, partly a clearing up from the past, and partly a preparing for the future, so that when the fine weather comes he may not have to waste any part of the beautiful spring days doing things that might have been done in the winter evenings. There are the nets to overhaul and put away for a short time after they are taken off the latest of the dwarf apples and pears; coverings to be got ready for the outdoor apricots and peaches, when in blossom; flower sticks to be tied up in bundles of a size; cleaning, arranging, and packing up the seeds of the past season which we thought it worth while to save; and, soon after Christmas, the study of catalogues, so that we may have all our selections made, and our plans decided upon for beds and borders, not forgetting one of the delights of winter evenings—the inspection of the fruit store, not only for the removal of any unsound specimens, but the selection of the next varieties to use in their best condition.

What little daylight we can get in the garden—assuming we are amateurs and busy men, as we all are nowadays—there is always enough digging or earth-work of some sort to keep us physically fit during the winter, and if we have not a great deal of digging we shall be wise to make what there is hold out by double or three-spit trenching, and burying all the rubbish and refuse we can get hold of, and then, if there is a dry summer, we shall see the good results of it.

Is anything more beautiful at any time of the year than a clear frosty morning, not too sharp, perhaps only just sharp enough to add zest and enjoyment, as well as cleanliness, to a nice piece of digging? In a sudden sharp spell there are many things which want looking after, things becoming urgent which we scarcely realised needed doing before. There are sure to be some subjects which want mulching to make them safe, such as tritomas, some kinds of clematis, tea roses, half-hardy climbers like Eccremocarpus scaber, and any newly-planted trees or shrubs; while the frames must be seen to, and any plants for which there is no room in them set together in a sheltered corner, and protection of some sort thrown over them. Then the celery, celeriac, and leeks must be looked after, and enough taken up at the beginning of the frost to tide us over a bad spell if it should come.

There is always a zest about this work when frost first comes, as it is a change from the business of the past ten or twelve months; and when we have it all done, and the tender things in the garden are made safe, or as safe as we can make them, and nothing remains that we can do, then, if the cold continues, we can go out and enjoy the winter country, with its wondrous frost and snow pictures, and give ourselves up to it, with the delight of coming home comfortably tired in the twilight of a keen winter afternoon to see a blazing fire and a well-spread tea table, and—the crown to all—happy faces round it. It is such a change to feel that there is nothing we can do in the garden—a sensation we do not experience by daylight for ten months at least of the year—that, however enthusiastic we may be in the work of the garden, there is a great pleasure in being able to give it up without self-reproach. As a mother said once: "I am very fond of my children, but I was glad to be away from them for a few days."

Then, when the frost goes, if only for a little while, it seems like spring, especially before breakfast, and there is a softness which is often wanting in May, while the thrushes and blackbirds are already in song.

ALGER PETTS.

THE CHARM OF WINTER: A WINTER SCENE IN THE GARDENS AT OAKWOOD, WYLAM-ON-TYNE.

APPLE NOTES, 1913.

Every season has its peculiarities, and in few things are the results manifested so markedly as in the apple crop, and that sometimes in a way quite different from what we should expect. In the exceptionally hot summer of 1911, many varieties scarcely began to colour until the weather changed in the middle of September; and they were ready to gather little, if any, earlier than usual. The summer of 1912 was a cool one, with a cold and wet August, and apples were ready to gather a week, or even a fortnight, earlier than was the case the year before.

The behaviour of apples in 1913 has been, perhaps, more normal, more what we should have been led to expect from the weather of the year. Some expressed surprise that apples were so late in maturing in such a beautiful autumn, but they forgot that the sun and warmth of the short days did not make amends for their absence in June, July, and early August. It was frequently remarked at the Fruit Show at the Royal Horticultural Hall that there was a general appearance of immaturity in the apples, so many looking as if they ought to have had another month on the tree; and it was not to be wondered at, as the show was a week or a fortnight earlier than has sometimes been the case, and those who arranged the date a year before could not foresee that this was going to be a season of delayed maturity.

There is no doubt that the size of apples suffered from the dryness of the ground in July and August, for, though there was no great drought or heat, but, on the contrary, a cool summer, with a good many showers, the soil a foot below the surface was practically untouched by rain in many places from May till October.

This was so, at least, in Essex. There is no doubt this answers the question which has been asked as to the failure of some varieties to swell as they should do, especially on heavily-laden standards, where in some cases the fruit seemed to remain about the same size during most of August and September, not beginning to swell at all fast until the heavy rains of late September and early October, after which it attained a fair size where it was allowed to hang long enough.

On dwarf trees, where a mulch was applied, and perhaps a little help given in the way of food and water, apples grew to a good size—in many cases well above the average—as growth continued so late owing to the warmth and dampness of October. This late growth, however, was not always favourable to colour, and possibly the result will be seen in some amount of shrivelling amongst the late varieties after Christmas, this being often noticed where growth continues late in the autumn, as on wet soils.

As curious instances of unwonted size among dessert varieties in my own garden, I might mention that I had several specimens of Lord Burghley, Adam's Pearmain, Duke of Devonshire, Egremont Russett, and even Sturmer Pippin, weighing seven ounces each, and even more in the case of the first-named, while six ounces was quite a common weight.

It has been suggested that apples will not keep well this winter. That depends on several circumstances. Where people took fright at a few fruits dropping, and had mid-season and even late varieties gathered in September, while the temperature of the fruit room during October was often as near 60 as 50 degrees, the ripening process must have been very much hastened, even among the late varieties.

Where apples were allowed to hang until the latter part of October, or even the early part of November, and then kept in a cool room, there does not seem any reason why they should not keep as well as usual — provided all with even the smallest speck or puncture are kept away from the sound ones.

I may mention the way I treated my Blenheim Oranges as an illustration of the varying keeping qualities of the same variety. I began gathering these early in September, and made a picking every week until the last week in October, all from the same tree. The result was that I had specimens in good dessert condition as early as the middle of October, while those gathered last were still green and unattractive in November.

Most people find a good deal of Codlin Maggot about this year where spraying was not done for it, while complaints of injury by birds or wasps, or both, seem universal. If all such damaged specimens of choice dessert sorts are put by themselves on easily accessible shelves, with the damaged part uppermost so that the eye can easily look over them every few days, most of them may be obtained in fair condition for eating, and none of them need be wholly wasted.

THE CHARM OF WINTER: THE QUEEN 'S COTTAGE, ROYAL GARDENS, KEW, AFTER A SNOWSTORM.

ORNAMENTATION IN THE JAPANESE GARDEN.

The whole subject of ornamentation in the Japanese garden is too complex for full consideration within the confines of a short article. Japanese gardening is an art elaborated to such a degree as to be practically beyond the scope of the average European garden-maker's mind and craft. A wealth of material is drawn upon, many diverse phases are portrayed, each separate feature has its own meaning, and yet all are essential in a carefully-ordered scheme.

To assert that certain definite artistic objects in stone and bronze are necessary for a Japanese garden would be the greatest mistake imaginable. Everything depends upon the garden itself. The true Japanese garden may portray a mountain torrent, a wind-swept grassy moorland, a maple valley, an iris swamp, or even the Isles of Matsushima or the mountains around Nikko. Judge, then, how any set formula of ornamentation would answer for each and all of these ideas.

However, a discussion of the various stone lanterns, etc., may do good. These lanterns are chiefly in granite, though some are in bronze, and many of the latter are very elaborate. First utilised for the needs of the ancient Japanese temples, they provided a fitting opportunity for the quaint artistry of the old-time workers in stone. At a very early date they were introduced into landscape gardening by the artists of those early times, and distinct positions were assigned to the various varieties. Without going into all the different types, I may briefly name the Snow-scene, the Valley, and the Low Basin shapes among the dwarf lanterns; and the Kasuga, Dragon, Shrine, Oribe, and Mile-post shapes among the tall lanterns.

The lantern-head is carved out to receive an oil lamp, and the faint fitful light from these lamps, glimmering through waving bamboos, lighting up the branches of some dark pine, or catching the ripples of the lake, and turning them into scales of silver, is a very beautiful artistic touch. We may utilise the tall lanterns by the sides of hills, or against a beautiful shrub or a grove of trees. The low lanterns are for the valleys, the water-sides, and foot-ways, and the broad-roofed Snow-scene lanterns are modelled to catch and hold the flakes of falling snow.

Hanging lanterns of bronze are used for suspending from the eaves of tea-houses and dwelling-houses, and are thus serviceable for lighting the verandah.

Bronze standard lanterns (often very beautiful) have no real garden value, and, with the Japanese, are devoted to temple service. Garden pagodas, or stone towers, are hewn out of similar stone to the garden lanterns, and are small reproductions of the Chinese pagodas, in simple style. They vary in height and design, and are usually made in three or five tiers, but there is no fixed rule as to the number. They are chiefly used on hillsides, and in association with weather-worn rocks, gnarled and partially-stunted trees, and help to give an idea of a greater distance than really exists.

The Water-basin lantern, always seen in gardens in Japan, has, of course, its utilitarian purpose, and if introduced into Anglicised Japanese gardens must be carefully placed. The simplest type is that hollowed out of natural rock, and if this can be arranged so as to be supplied from a small cascade or a dripping well so much the better for the garden effect.

However, there are other ornamental patterns, but I may say that the Stone Jar and the Stone Bottle shapes are very simple in design, and associate with the ordinary shrubs, etc., of the Japanese garden. In the case of lanterns, water basins, pagodas, etc., there is also the inevitable association of stepping-stones.

Then there are the bronze eagles, monkeys, cranes, deer, etc. These are usually very fine productions, and perhaps the cranes are the greatest favourites with garden-makers; but to my mind the best touch of beauty is the introduction of a pair of real cranes, which are exquisite, especially if in a garden arranged with waterways in a natural style.

Bronze and metal work are not used in gardens in Japan, like stone and wood work, so I would not urge their adoption here, but may I say that many of the masterpieces of the Japanese metal-workers would grandly grace an English hall, and would associate splendidly with a background of dark oak. P. S. HAYWARD.

STONE LANTERNS IN THE JAPANESE GARDEN AT FANHAMS HALL, WARE.

ALBINO CYPRIPEDIUMS.

Among the many different and beautiful cypripediums probably none have been so eagerly sought after as the pure albinos, and as these have, during the last few years, received some notable additions, it may be of interest to briefly note the history of this class.

The honour of exhibiting the first pure albino belongs to R. Brooman-White, Esq., and the Messrs. Linden. It was at the meeting of the Royal Horticultural Society, held on April 27, 1886, that the now well-known C. Lawrenceanum Hyeanum, named in honour of Mons. Jules Hye, Ghent, was first shown, and received a First Class Certificate. This remarkable variety caused a great sensation, the beautiful albino having a dorsal sepal of the purest snow-white, veined with light green, the petals being yellowish-green with deeper green veins, and the pouch bright green, netted with veins of a brighter hue, the whole making a superb variation from the normal form.

The second pure albino appeared at the Temple Show in the year 1894, when Messrs. Sanders and Sons exhibited the beautiful C. callosum Sanderæ, and obtained a First Class Certificate for this charming variety, which is more graceful in form than C. Lawrenceanum Hyeanum, to which it is comparable in colour. During the same year C. insigne Sanderianum, the true albino of this popular species, appeared; a charming variety, smaller than the type, having flowers of light yellowish-green, with darker green reticulated veins, and a broad white border to the dorsal sepal. This was introduced by Messrs. Sander and Sons, and exhibited by the late Baron Schroder at the meeting of the Royal Horticultural Society, held December 27, when it secured an Award of Merit.

The year 1895 saw a most beautiful addition to this group of albinos, and great was the surprise at the meeting of the Royal Horticultural Society, held on June 11, when C. bellatulum album was shown for the first time. It was introduced by Mr. R. Moore, of Bradford, and flowered in the collection of the late Sir Frederick Wigan, Bart., who exhibited the plant, which deservedly received a First Class Certificate. It is the purest albino cypripedium we have, being quite white throughout, save for a little yellow in the centre of the staminode.

The year 1900 will always be remembered for the flowering of C. Maudiæ, a cross between C. Lawrenceanum Hyeanum and C. callosum Sanderæ. The flowering of this hybrid gave proof that albinism is a character which can be reproduced true from seed. This interesting hybrid was raised by Messrs. Charlesworth and Co., but was not, however, certificated until July 30, 1901, when the variety magnificum was exhibited by the late Captain G. W. Law Schofield, and obtained a First Class Certificate. The accompanying reproduction of a variety of this charming orchid shows its intermediate character and gives an excellent idea of its beauty. It is probably the best of all the albinos, and certainly yields to no other orchid in the ease with which it can be grown and flowered.

C. Rossetti was the second hybrid of this class to appear, and made another very important contribution to the subject of inheritance of labinism. This very beautiful cypripedium is the result of crossing C. insigne Sanderianum with C. Maudiæ. It was raised at Westonbirt, and exhibited at the Royal Horticultural Hall by Sir George Holford, on August 18, 1908, when it received an Award of Merit. Since then much finer forms have been shown, but, strange to say, they have failed in each case to gain the higher certificate. C. Rosetti is a beautiful bright yellow flower, with some green veining on the dorsal sepal, and the upper part white; it shows no trace of any other colour, thus proving that C. i. Sanderianum is the true albino of

A FINE SPECIMEN OF CYPRIPEDIUM MAUDIÆ.

C. insigne, as C. i. Sanderæ and C. Maudiæ, previously crossed together, produced all coloured flowers. During this same year another very beautiful albino was recorded. On October 13, H. J. Bromilow, Esq., exhibited Cypripedium Charlesworthi Bromilowianum, which received a First Class Certificate. There is no trace of the usual brown markings in this variety, the dorsal sepal being pure white, with a small green marking at the base; the petals and lip are pale green, and the staminode porcelain-white. This charming albino, used as a parent with either of the above, should prove most valuable to hybridists.

H. ALEXANDER.

The Gardens, Westonbirt.

SHRUBS FOR THE ROCK GARDEN.

A rock garden without shrubs would present a rather flat appearance, and be somewhat bare at certain seasons of the year, especially when the alpine plants were not in blossom. The inclusion of shrubs of moderate growth gives character and diversity, besides adding to its floral attractions very considerably. In addition to the use of flowering shrubs there are several evergreen kinds that are especially suitable, as they lend a certain warmth and individuality to the rock garden during the winter months when a rock garden is least attractive.

It is very necessary to choose shrubs that will not encroach on the alpine treasures when they reach maturity, and it is foolish to choose those which are gross feeders. There are, however, a number of desirable shrubs for the purpose in view, and in a great many instances a rigid selection will have to be made. The more vigorous kinds must of necessity be placed in the background, and in large rockeries composed of massive boulders these will prove a most desirable addition to the arrangement.

One plant in particular that might be more generally used is Juniperus prostrata, and when planted behind large rocks, so that it can grow naturally over them, it is very effective. This juniper has been rather largely utilised here in such manner, and is greatly admired by visitors. Dwarf rhododendrons are especially good. R. racemosum is one of the best, and its beautiful rose-pink blossoms, produced in dense clusters, are very showy. R. ferrugineum, with rich pink flowers, and R. myrtifolium, with delicate rose-coloured blooms, should both be grown; while R. præcox bears rosy-lilac flowers quite early in the year. Azalea amœna, with crimson-purple blossoms, and A. rosæflora, a charming kind with double salmon-pink flowers, are both very useful. A. mollis and its varieties may be planted with great effect, as no other shrubs give a brighter display of bloom, and, in common with the rhododendrons, they flourish best in a light peaty soil.

Several of the berberis are serviceable, and of these B. stenophylla is one of the most graceful, but it requires judicious pruning to keep it within bounds. B. Darwini nana is also attractive, and B. dulcis nana is a delightful little shrub of quite compact growth. B. Wilsonæ is likely to become a great favourite; while in the autumn none surpasses B. Thunbergi for brilliance of foliage.

The cotoneasters should be represented by C. microphylla and C. horizontalis, their crimson berries in autumn being a great attraction. Cydonia japonica Simoni, with its deep crimson blossoms, should be planted; and Ægle sepiaria looks quite at home on the rockery, its rich golden foliage in late summer and autumn making it very showy.

Some of the daphnes create a beautiful effect, and D. blagayana, with lovely ivory-white blossoms, should always be grown. It succeeds best when its branches are held down by a number of loose stones. D. cneorum succeeds under similar treatment; its flowers are soft pink, and deliciously scented. Choisya ternata thrives among the rocks, but needs a sheltered position; its white waxy flowers are very sweet. Cytisus nigricans is valuable, as it flowers later than most kinds, and C. præcox is especially showy. C. kewensis should never be omitted, as its trailing habit renders it ideal for planting to hang over the rocks, while its creamy-white flowers never fail to please.

For planting in a dry position Genista hispanica is quite a good subject. It is dwarf in growth, and its bright yellow blossoms are very showy. G. pilosa is a prostrate variety that should be included. Hydrangea petiolaris is quite a distinct plant of loose spreading growth, and its creamy-white flowers are light and pretty. Several of the shrubby spiræas are worthy of inclusion, and of these S. bullata, a dwarf Japanese species, with bright crimson blossoms, is one of the most distinct; while S. Thunbergi and S. japonica Anthony Waterer may also be planted. The double-flowered furze (Ulex europæa fl. pl.) is especially showy when in bloom, and is well worth a place.

Then there are the Rock Roses that are so bright when in blossom, and of these Cistus florentinus is a compact variety growing 2½ft. high, with beautiful white blossoms produced freely throughout the summer. C. algeriensis is a dwarf variety with bright yellow flowers; and C. ladaniferus has large white flowers with chocolate blotch. Prunus prostrata is quite a dwarf plant, smothered in rosy-white blossoms in spring; and P. pumila is a diminutive species that flowers freely, while the foliage turns a brilliant crimson in the autumn.

The hardy heaths must not be omitted, and of these probably Erica carnea is the most desirable, as it produces its rosy-red blossoms from January to May, and looks extremely pretty among the rocks. E. australis, E. codonodes, E. mediterranea, and E. m. hybrida should all be included. Romneya Coulteri (the Californian Tree Poppy), a very handsome plant with large white flowers, prefers a warm position and light, well-drained soil. Several of the veronicas should be planted, as they are ideal plants for the rock garden. The magnolias are strikingly handsome, and are especially effective in early spring; M. stellata is one of the most beautiful, with its white blossoms; while M. conspicua and M. Soulangeana should certainly be planted, if space permits. Another subject that looks very well is Ilex Pernyi, a dwarf Chinese holly.

J. GARDNER.

Batsford Park Gardens.

Echeveria fulgens.—This plant, now included in the genus Cotyledon, is a bright-flowered subject for the greenhouse during the winter months. Apart from any other consideration, its continuous flowering qualities stand it in good stead. It forms a sturdy stem, 6 to 8 inches in height, and is furnished with rather pale, glaucous-green leaves. The flowers, borne in panicles, are tubular, and of a bright red colour with a yellow base. E. fulgens is a native of Mexico, and has been long known in this country.—S. W.

NEW PLANTS AND FLOWERS.

STANHOPEA GRANDIFLORA.

A well-known and handsome species that belongs to the earliest day of orchid collecting. It was originally described and figured by Humboldt and Bongraud in 1805 as Epidendrum grandiflorum, from plants collected in shady woods near Cuneca, in Ecuador. Later it was transferred by Kunth to Anguloa, and subsequently it was placed by Reichenbach the younger in its true genus as Stanhopea grandiflora. The flowers are relatively of large size and showy, the petals and sepals are yellow, the lip white, and the column greenish-white, the whole of the segments being blotched with purple. Bot. Mag., t. 8,517.

RHODODENDRON HÆMATOCHEILUM.

A Chinese species, raised by Messrs. J. Veitch and Sons from seed collected by Mr. E. H. Wilson. The flowers are of medium size, and borne in elegant trusses, the colour of the corolla is deep red when partly expanded, but bright carmine when fully developed, with white throat. It has proved hardy in the Coombe Wood nurseries, and thrives under the same conditions as the other rhododendrons that have been introduced from China within recent years. Bot. Mag., t. 8,518.

NAUTILOCALYX PALLIDUS.

An interesting plant, which was sent from Peru by Mr. Forget, when collecting for Messrs. Sander and Sons. It has stout, fleshy stems, of which several are produced from near the base, and the flowers are cream-white, and borne in cymes along their whole length. It thrives in a warm greenhouse. Bot Mag., t. 8,519.

SCHIZOPHRAGMA HYDRANGEOIDES.

This is the true Schizophragma hydrangeoides, which is a comparatively recent introduction, and appears to have first bloomed in this country with the late Mr. B. E. Chambers, of Grayswood, Haslemere. The flowers are cream-white, and produced in a terminal corymb, the fertile flowers very small, and crowded, and the sterile flowers, which are confined to the margin of the corymb, are reduced to a single membraneous cream-white cordate or ovate bract. It has a scandent habit, and is described as reaching the tops of trees forty feet in height. The plant which has during the past two generations been common in English gardens under this name is Hydrangea petiolaris, an allied climbing Japanese shrub. Bot. Mag., t. 8;520.

STREPTOCARPUS CYANEUS.

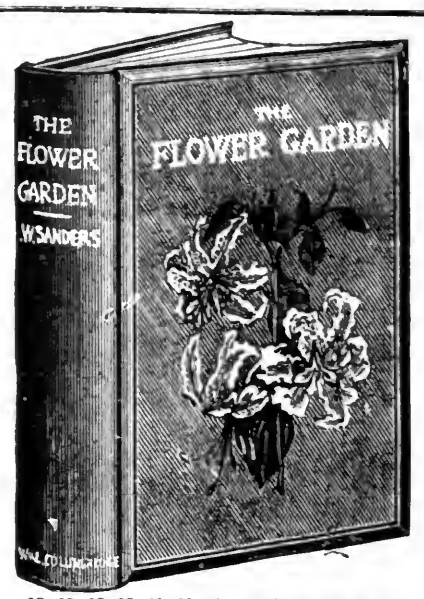
This attractive species is described as closely allied to the well-known S. Rexi, but differing in having the corolla tube much shorter and more dilated at the throat. S. cyaneus was first met with in 1891 by Mr. E. G. Galpin in wooded kloofs near Barberton, but the specimens on which the original description was based were collected in 1905 by Mr. J. Burtt Davy, who found them growing on rocks and tree trunks in dense shade at Forbes Reef Bush, in Swaziland. The flowers vary in colour from pale lavender or blue to rose-pink or rose-mauve; in the latter case the two upper lobes shade into blue in the central area. Bot. Mag., t. 8,521.

RHODODENDRON SETOSUM.

A neat little species found on the moorland tracts and rocky slopes characteristic of the loftier passes leading across the Eastern Himalaya into Tibet, within a few miles of the summits of which it reaches its uppermost limits. "Here," it is stated, "the brilliant red-purple flowers render the species a charming object, and, after hot sunshine, the air is filled with the heavy aroma due to a copious resinous secretion, which testifies to the comparatively dry climate it enjoys." It is suggested that, from its dwarf habit and slow growth, it is best adapted for the rock garden, and that a peaty soil should be provided for it. Bot. Mag., t. 8,523.

GIFTS FOR GARDEN LOVERS

There is no Gardener to whose affections a present of any one of these books would not be a sure passport.



AN IDEAL GIFT FOR GARDEN LOVERS.

THERE IS NO FAIRER SPOT THAN A PROPERLY FASHIONED ENGLISH FLOWER GARDEN. HERE IS A GUIDE TO SUCCESS.

THE FLOWER GARDEN.

How to make it, and how to manage it.

By T. W. SANDERS, F.L.S. A comprehensive work of nearly 500 pages, with full indexes, etc., and Illustrated with 64 full-page Engravings, and numerous smaller ones.

The Contents include—GARDEN DESIGN. FASHIONING IT. COLOUR ARRANGEMENT. BEDS AND BORDERS. WALKS AND PATHS. ARCHES AND PERGOLAS. EDGINGS. ARBOURS AND SUMMERHOUSES. ROCKERIES. FERNERIES. WATER, WILD AND JAPANESE GARDENS. SHRUBBERIES. LAWNS AND TENNIS COURTS. WALLS, HEDGES AND FENCES. PLANTING. PRUNING. PROPAGATION. BEDDING. ROSES. PERENNIALS. ANNUALS. BIENNIALS. HARDY BULBS. WATER PLANTS. FERNS AND MOSSES. CLIMBERS AND TWINERS. TREES AND SHRUBS. GARDEN PESTS AND DISEASES. TOOLS ETC., ETC.

Crown 8vo. Handsomely bound in bevelled cloth. **7/6** net. By post **8/-**

A FEW PRESS OPINIONS—

"One of the best Gardeners' Guides we have seen for some time is 'The Flower Garden.'"—YORKSHIRE POST.
"It may be thoroughly commended as a reliable guide."—GARDENERS' CHRONICLE.
"Crammed full of useful information . . . . . of infinite value."—JOURNAL OF HORTICULTURE.
"Contains a perfectly marvellous amount of information in comprehensible form."—LADIES' FIELD.

EVERYTHING ONE NEEDS TO KNOW TO MAKE THE MOST OF A GARDEN.

THE BEST BOOK EXTANT ON THE GROWING OF VEGETABLES.

VEGETABLES AND THEIR CULTIVATION.

By T. W. SANDERS, F.L.S., F.R.H.S.

A REALLY PRACTICAL WORK ON THE CULTIVATION AND FORCING OF ALL KINDS OF VEGETABLES. 500 PAGES, WITH MANY ILLUSTRATIONS IN COLOUR, HALF TONE AND LINE. STRONGLY BOUND. **5/-** NET. BY POST, **5/4**

PRESS CRITICISMS:—

"We have no other words than praise for the excellence of its contents."—GARDEN.
"We confidently recommend the work to all interested in Vegetable Culture."—R.H.S. JOURNAL.
"It is an excellent book."—GUARDIAN.

YOUR "UTILITY-IN-THE-GARDEN" FRIEND WILL APPRECIATE EITHER OF THESE VOLUMES.

FRUIT AND ITS CULTIVATION.

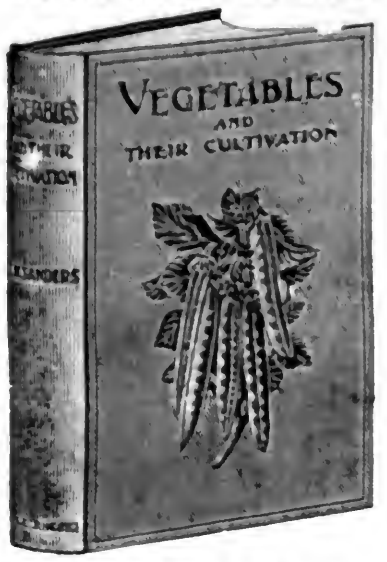
By T. W. SANDERS, F.L.S., F.R.H.S.

A NEW BOOK WHICH WILL BE REGARDED AS A STANDARD WORK ON THE CULTIVATION OF ALL KINDS OF HARDY FRUITS IN GARDEN AND ORCHARD. HANDSOMELY BOUND. CLOTH GILT. 372 PAGES. 64 FULL PAGE PLATES ON ART PAPER, AND 145 LINE DRAWINGS. **6/-** NET. BY POST, **6 4**

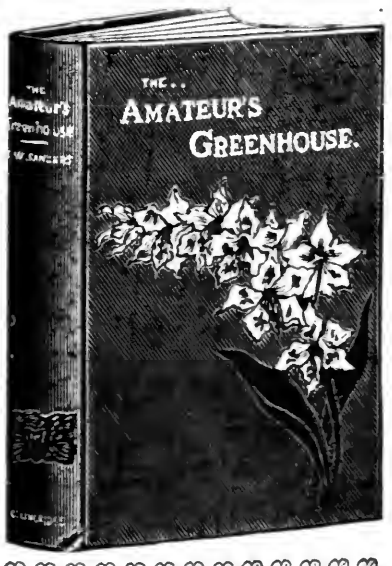
This up-to-date work truly may be termed an Encyclopædia of the Whole Art of Growing Fruit with Success. No matter whether the problem is to grow fruit in the Garden, Orchard or Plantation, herein will be found sound and practical information. Although written in the interests of fruit growers of all degrees, special attention is devoted to the requirements of Amateurs and those who desire as Smallholders to grow fruit for profit on their holdings. A splendid guide to a profitable pursuit.

UP-TO-DATE INFORMATION ON EVERY PHASE OF HARDY FRUIT CULTURE.

—NOT SCRAPPY— PICTURE BOOKS.



— BOOKS OF — PRACTICAL VALUE.



FOURTH EDITION A CAPITAL BOOK.

HE (OR SHE) WHO LOVES A GARDEN LOVES A GREENHOUSE TOO.

THE AMATEUR'S GREENHOUSE.

How to Construct, Heat and Manage it.

By T. W. SANDERS, F.L.S. A really excellent Book on the Construction, Heating and Management of Small and Large Greenhouses. 164 Illustrations in colour, half-tone and line.

The Contents include:—SITE AND POSITION. LEAN-TO AND SPAN-ROOF STRUCTURES. MODE OF CONSTRUCTION. TENANT'S FIXTURE. VENTILATORS. STAGING. VARIOUS HEATING METHODS. FLUES. TEMPERATURES. WATERING. FORCING. COMPOSTS. MANURES. FUMIGATING. SHADING. PROPAGATION BY LEAF, STEM AND ROOT CUTTINGS. OFFSETS. STEM ROOTING AND DIVISION. PESTS AND DISEASES AND THEIR ERADICATION. A LIST (OVER 300 PAGES) OF POPULAR GREENHOUSE PLANTS, GIVING SPECIES AND EVERY DETAIL FOR SUCCESSFUL CULTIVATION

Crown 8vo. Handsomely bound in cloth. **5/-** net. By post **5/4**

A FEW PRESS OPINIONS:—

"This is a handy book, and one that is likely to be of great assistance to the ever-increasing class of residents who either have greenhouses already or who intend to build one."—THE FIELD.
"The veriest tyro could become the happiest possessor of a beautiful greenhouse at a small cost, after studying this most useful volume."—BRISTOL TIMES.
"The book is one which may be warmly recommended."—READING MERCURY.

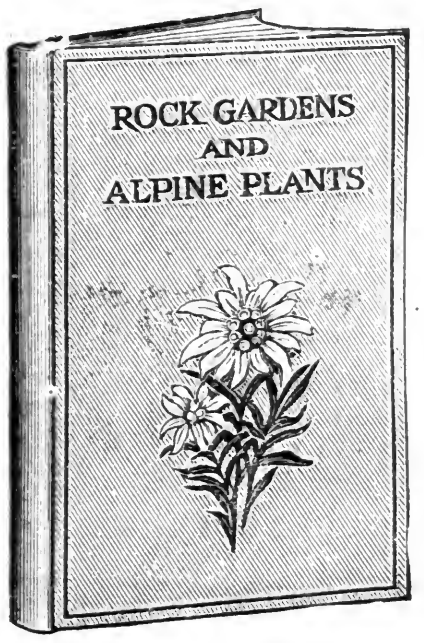
GIFTS FOR GARDEN LOVERS



ROCK GARDENS & ALPINE PLANTS.

By E. H. JENKINS, F.R.H.S.

A PRACTICAL GUIDE TO THE FORMATION AND MANAGEMENT OF ROCKERIES IN SMALL AND LARGE GARDENS, AND TO THE CULTIVATION OF EASILY-GROWN ALPINE PLANTS IN OPEN AIR, COLD GREENHOUSE, FRAME AND IN WINDOW BOXES.

CONTENTS.

CONSTRUCTION OF ROCKERIES.—Selection of a Site. Aspect and Position. Materials for Rockeries. Principles of Rockery Building. General Construction. Rock Gardens in Miniature. The Simple Rockery. Rock-studded Banks.

CULTURE AND MANAGEMENT.—Suitable Soils for Alpines. Grouping and Arrangement. Planting Alpines. Special Methods of Culture. The Alpine House. Alpines in Frames. Culture in Pans and Pots. Alpines in Window Boxes. Propagation.

SELECTION OF ALPINES.—Choice Kinds for the Rock Garden. Bulbs and Tubers for the Rock Garden. Hardy Ferns for the Rock Garden. Foliage and Flowering Shrubs. Free-growing Rock Plants. Hardy Orchids. Plants for Old Walls. Alpines for Greenhouse Culture.

MANY ILLUSTRATIONS.

The Best Handbook on the Subject.

ROSES & THEIR CULTIVATION

By T. W. SANDERS, F.L.S., F.R.H.S., Etc.

A PRACTICAL GUIDE TO THE CULTIVATION OF THE ROSE, OUTDOORS AND UNDER GLASS, WITH A SYNOPSIS OF THE DIFFERENT TYPES OF ROSES. SCHEDULE OF ALL THE VARIETIES WORTHY OF CULTURE IN BRITISH GARDENS. INSECT PEST AND FUNGOID DISEASES, AND HOW TO ERADICATE THEM.

"This book can be honestly recommended as far and away the best of its kind for the novice as well as the more experienced in the delightful art of rose culture."
—DUNDEE ADVERTISER.

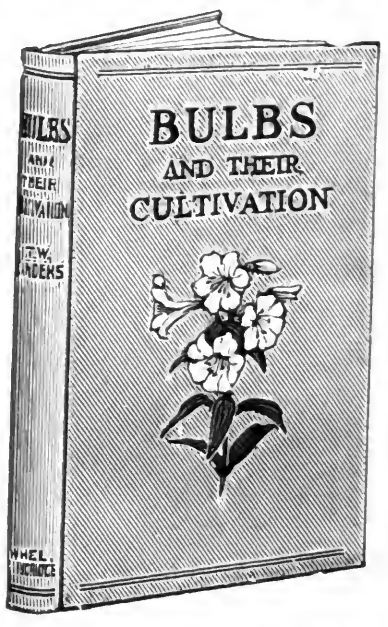
Ninth Edition. Now Ready. Splendidly Illustrated

IT GIVES THE WHY AND WHEREFORE OF ..... over 1,700 different Roses.....

Crown 8vo. Bound in Cloth. **2/6** net. By post, **2/10**

SPECIMEN ILLUSTRATION.

TEA-SCENTED ROSE "LADY HILLINGDON."



BULBS AND THEIR CULTIVATION.

By T. W. SANDERS, F.L.S.

A PRACTICAL TREATISE ON THE CULTIVATION AND PROPAGATION OF WINDOW AND INDOOR BULBOUS AND TUBEROUS-ROOTED PLANTS ADAPTED FOR OUTDOORS, GREENHOUSE, AND ROOM DECORATION, WITH LISTS OF SPECIES AND VARIETIES.

CONTENTS.

THE BEST BULBS.—A clear definition of each with description. Selections of the best varieties for growing in beds, rockeries, borders, pots, glasses, and bowls.

SOILS AND MANURES.—Most suitable soils and their preparation. The best manures—how and when to apply them.

PLANTING.—The best time to plant, depth, position, and arrangement for colour effect.

CULTURE.—General treatment in beds, borders, lawns, rockeries, woodlands, hedgebanks, and by the waterside; also culture in frames, fibre, water, &c.

PESTS AND DISEASES.—The pests described, preventive measures, and remedies for eradicating.

"Not only does this volume include full details necessary to culture, but it contains useful suggestions and fresh ideas of value to those desirous of introducing novel and charming effects."—SCOTTISH FIELD.

FULLY ILLUSTRATED.

A REMARKABLE HARTSTONGUE FERN.

As a peculiar instance of confirmed or fixed mutations in two generations, in connection with the well-known Hartstongue Fern (Scolopendrium vulgare), I send herewith an illustration of a constant form S. v. sagittato-grandiceps Druery, raised by me some years since under the following circumstances. A plant was found wild at St. Austell, Cornwall, in which the tips of the fronds were divided into three or four parts (S. v. lobatum), as is so frequently found to be the case where this fern is plentiful. In addition to this, however, the normally round lobes on the frond base were somewhat lengthened, and had a distinct midrib, while the ends of these were dilated and slightly forked as well. In view of these incipient characters, as the wild frond sent for my opinion bore plenty of spores, I made a sowing, with the result that a considerable number of plants were produced, the great majority of which varied from quite normal ones to others akin to the parent.

The majority were not considered worthy of preservation. The minority, however, consisted of no less than nine plants, all alike, and of the extraordinary type which is depicted in the illustration. In these the cresting, feeble as it was in the parent and the rest of its offspring, has been developed so strongly, not only at the frond terminal but also in the basal lobes, that the normal, strap-like portion of the frond has been entirely eliminated in favour of the terminal cresting. The result in many of the fronds is as shown, viz., three ball-like crests surmounting the stalk, each having its own midrib, and thus utterly transforming the fern.

Spores are very sparsely produced, but, of course, I took the first opportunity of testing their capacity, with the rather unexpected result, remembering the variability of the first crop, that every plant is an exact replica of the new form, thus showing that the mutation is fixed, and that the variable influence of the original find is eliminated. An additional feature is the occasional production of bulbils on the surface of the fronds.

In some fronds the cresting is still more exaggerated than in the one depicted, the three bunches being agglomerated into one ball, in which, however, the three midribs, indicating the retention of the sagittate or barbed character, are clearly traceable. There is an exotic asplenium (A. hemionitis), with fronds of the same tripartite or sagittate character, of which I found a tasselled variety in the Azores, and this has been exactly imitated by a wild, native scolopendrium spor (S. v. hemiontiodes) of which there is also a tasselled form. So far, however, nothing has been found or raised which at all resembles the variety now discussed. It should be particularly noted that the spores from which this section originated were taken from the wild original frond, and that consequently the mutation cannot in any way be imputed to cultural influence, nor to environment, since one and the same form yielded both the variable progeny described, and the nine remarkable plants found amongst them.

CHAS. T. DRUERY, F.L.S., V.M.H.

Eupatorium vernale.—This is a most useful plant for flowering after the chrysanthemums, but in order to keep it from blooming too early it must be kept as cool as possible. We have a batch still in cold frames, and it will prove of great value during the month of January.

HERBACEOUS LUPINS.

Lupinus polyphyllus is a plant of great beauty; it is one of the most reliable of June-flowering perennials, and, once established, it lives to a great age, succeeding in practically any kind of soil, although it naturally prefers one that is light. Too frequently one finds it represented in gardens by plants far too small to give any decided effect; in small gardens, where space is always at a premium, this cannot well be altered, but in larger gardens it should be represented by masses of several yards in extent, placed in commanding positions, for the lupin is a stately subject, that imparts dignity to a June border.

A REMARKABLE HARTSTONGUE FERN.
(Scolopendrium vulgare sagittato-grandiceps.)

Among the numerous varieties in commerce at the present time I would include four under this arrangement, namely, the type, for its rich shade of blue, the variety Foxi, for the beautiful charm of its bicolor flowers, which are neither flaked nor bizarre, but one half of the flower clear blue the other pure white; then the variety alba, quite a creamy-white in the early stages, but having greater purity in the developed flowers; and, lastly, the variety Moerheimi, with its captivating flowers of delicate pink, the keel only a trifle deeper than a blush, while the standards incline a little to rose. There is a stately dignity in the manner in which those ample spires of colour rise above the soft, yet luxuriant, mound of leafage, and instinctively with the opening of the lupin comes the impression that the season of brilliant sunshine and of flowers is with us.

Although herbaceous lupins are border plants of the highest excellence there are other positions wherein they acquit themselves with merit. They are ideal subjects for the pleasure grounds if given positions where they receive a fair amount of light. If the ground is deeply worked before planting success is assured, and then practically few perennial plants can surpass them for a lasting and economical display.

Lupins may safely be planted any time during the dormant season, and only in few cases should the addition of farmyard manure be made when planting; ordinary garden soil is generally rich enough for their requirements, while planting should be carried out with the intention of allowing the plants to remain undisturbed for several years.

S. H.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

SEED SOWING.—At the present season there are seed vessels ripening on many orchids, more especially the cypripediums. From the present time onwards the seeds may be sown as they ripen. There is little progress made under the most favourable conditions at this season of the year in respect to germination, but in the case of most seeds slow germination is desirable, and the prevailing conditions are such that the plants will remain in a moist state for some time, so that frequently watering the seed beds is unnecessary. This is an advantage, for if there is one thing more fatal to germination than another it is the necessity of frequently watering the seed beds, and, however carefully this operation is carried out, it is a difficult matter to prevent floating the light seeds from the positions in which they have been placed. Any carelessness in the application of water washes the seeds over the sides of the pots to destruction. The desirability of inducing the seeds to commence germination with the least possible need for watering will thus be apparent.

SEEDS OF WINTER-FLOWERING CYPRIPEDIUMS we sow now as soon as ripe. It is desirable to select plants for seed beds that have been repotted a few weeks previously, or those which have the surface of the potting compost in a good state of preservation, and are likely to remain good for at least two years. The germination of cypripediums is very erratic. Seeds from the same capsule may be sown on a half-dozen surfaces, and seedlings will only appear on one or two of them. In some cases, from the same seed vessel, the seeds may be found germinating in a few days in one or more pots, and it may be a year or longer before any sign of germination is shown in others. Then, again, no sign of germination may appear for a year or more, till, after giving up all hope, we suddenly find a good crop of seedlings.

SEEDS OF C. ANGELA (Fairieanum × niveum) germinated on a plant of C. niveum after the earlier plants from the same sowing had flowered. It will generally be found that seeds of winter-flowering cypripediums sown in December or January usually germinate steadily, and have the advantage of lengthening days to gradually assist development, and so good plants are obtained the first year. It is desirable that the seed beds should be thoroughly moistened the day previously to sowing.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

THE CONSERVATORY.—Now that the chrysanthemum season is drawing to a close the provision of flowers for the conservatory will require much care and forethought. Shrubs which were potted up in November will readily force now, but in order to keep them in bloom as long as possible they should not be taken direct from the forcing house to the conservatory, but be removed from the warm house, just as the flowers begin to open, and placed for a few days where they can be gradually inured to cooler conditions. By this means the flowering season will be considerably lengthened. The early-flowering tulips and narcissi can readily be forced into flower if they were potted early enough in the autumn to be well rooted by now. Where large quantities of cut flowers are in demand some of the most promising of the flowering shrubs which were planted outdoors two years ago may be dug up and placed in a fruit house which has been just started. The well-being of flowering plants at this time of year depends in no small measure on the way they are watered. Where the conservatory is connected with the dwelling the temperature often has to be kept up to 60 degrees, and this, of course, is not good for some of the grown plants. In these circumstances every favourable opportunity should be taken to admit air, even if only for a very short time.

LACHENALIAS.—These bulbous plants are most useful for the front of the stages in the conservatory, or for hanging baskets. Unless they are needed to bloom at an early date they will be the better for cool treatment for some time to come. They should not, however, be left longer in cold frames. A position on a shelf, near the glass, in a greenhouse temperature will suit them until they flower. The pots are now becoming filled with roots, and it will be advisable to give a mild stimulant when watering.

CLEANING GLASS HOUSES.—Now that other work is not so pressing, the cleaning of glass houses, both inside and out, should receive attention. The exterior of the houses, especially when they are situated near large towns, needs at least an annual cleaning. Inside the houses the whole of the plants should be removed, so that every part of the structure may be thoroughly dealt with. It is a good plan, too, at this time of year, if the houses can be kept empty for a few days, to have the woodwork painted.—E. Harriss, Lockinge Gardens.

HARDY FRUITS.

PEACHES AND NECTARINES. — Although the season was favourable for the ripening of young fruiting wood, the shoots are rather soft and green at the present time, and the buds, owing to the mild autumn, are too forward. The pruning and regulating of the branches we shall leave until the beginning of February, being satisfied for the moment in bringing up all arrears in other pruning. Plums, pears, Morellos, and other cherries on walls we have now finished with, and bush and espalier trees will next receive attention in favourable weather. We shall give the heads a good thinning out to admit light and air, and to encourage the main branches to build up strong, fruitful buds, which will produce good crops of useful fruits, clean and well coloured.

ESPALIER PEARS.—Where these have been rather neglected, or where, through age the tiers have become clothed with long, useless snags, several old spurs should be removed at each pruning until they have been replaced by healthy buds, much nearer to the main wood. Sever these old spurs with a keen-edged pruning saw to within an inch or so of the main wood; pare the wound with a sharp knife, and leave all neat and clean. In this way, I have, in a few seasons, entirely clothed branches with fruitful spurs.

APRICOTS.—In some gardens the apricot does not thrive so satisfactorily as in others, but where the fruits are appreciated young trees should be planted on a west wall, and given a well-drained site, so that water can pass away with freedom. Let the soil consist of mellow, fibrous loam, with plenty of old brick mortar added. If the staple is rather poor, add old, decayed manure. The compost should be thoroughly mixed, and rammed, if moderately dry, fairly hard; rest the roots on a firm basis; do not bury the stem deeply, and allow six inches between the wall and the stem, so that the latter may swell without harm. The stems of all stone fruit trees planted on south walls should be protected during hot, bright weather.

THE WEATHER continues very mild, and weeds among strawberry plants must be pulled up; hoe or slightly point the soil among the plants, and mulch with manure, if not already done, packing this well round the plants to protect them against a sudden change to severe weather. I have known much injury follow severe frost after a mild autumn. In inclement weather prepare shreds, overhaul nets, and see that all the protecting material is put in order, so that when the time arrives in spring everything will be in good order, and thus prevent delay at a critical time.—H. Markham, Wrotham Park Gardens.

THE KITCHEN GARDEN.

POTATOES.—Where early potatoes are required in quantity, further preparation should at once be made to meet the demand. A heated span-roofed pit is an ideal structure for the purpose but is seldom available, and so the ordinary lean-to pit has to serve; if it is heated so much the better, as there is then less labour needed in making up deep hotbeds required in the old-fashioned cold pits. When dealing with the latter it is necessary to gather together as quickly as possible the necessary amount of leaves and fresh manure to form the hotbed; this mixture should be turned over until the excessive heat has escaped, and then be transferred to the pits; make it thoroughly firm by treading as the work proceeds. The linings should be applied at the same time, and these can be renewed as occasion requires. As soon as the heat is again established the compost should be placed on the bed to a depth of 7 or 8 inches. This should consist of fresh loam (if possible), and a sufficient amount of leaf mould to make up a light, friable mixture; the whole should be passed through a sieve, and if the loam is of a poor nature, add sifted, well-rotted manure, preferably that from an old mushroom bed. A good dressing of wood ashes will be beneficial. When the heat of the bed is on the decline the potatoes may be planted. The sets, if prepared as previously advised, will be well sprouted, and should be planted a foot apart each way for such varieties as Sharpe's Victor and Ashleaf; stronger growing varieties should be allowed more space.

FRENCH BEANS. — Further sowings should be made in pots, starting them in a temperature of 55 degrees, and giving a higher temperature when they have germinated. The best soil for French beans is loam, used in a rough state, and old mushroom-bed manure. The pots used need not be larger than 8 inches in diameter. The warmth may be increased to 65 or 70 degrees by the time of flowering, and a light position near the glass is very essential to success. When not in bloom the beans must be thoroughly syringed daily, or red spider will ruin them.

MUSHROOMS.—While mild weather continues, artificial heat should be used sparingly, using just sufficient to maintain a temperature of 55 to 60 degrees. If any mushrooms turn black, the degree of warmth and the humidity of the house must be reduced. A steamy atmosphere causes discolouration, and a very hot or dry one shrivels up the young mushrooms. Beds which have been in bearing for some time will be much assisted by a good watering, using liquid farmyard manure thoroughly warmed.

CUCUMBERS.—A further sowing may be made during the present month, potting the seeds singly in small 60-sized pots, and placing them over a strong bottom heat. When germination takes place afford a position near the glass, where they will have the benefit of high temperature and moist atmosphere. These, if carefully attended to, should be ready for planting out on well-prepared beds by about the third week in January. Plants in full bearing should be trained thinly, and not overcropped, and the greatest care should be taken to keep them in a healthy condition.—W. Messenger, Woolverstone Park Gardens.

ROSES FOR GARDEN DECORATION.

(Concluded from page 965.)

Rose Enemies.

The one most in our mind and gardens just now is mildew. Everyone knows that this is a fungoid growth that appears as a white mould on the foliage and stems of the plants, and is particularly noticeable in the autumn. To guard the plants from injury by this enemy we must not wait until it appears. Prevention is better than cure, and our first step must be taken as soon as the leaves of the roses appear in the spring. A simple solution, recommended by the Rev. J. H. Pemberton, ex-president of the National Rose Society, is Calvert's carbolic soft soap: Boil 1½lb. of this soap in 7½ quarts of water, and, when preparing a solution for spraying, add one part of this mixture to six parts of soft water. Mr. Pemberton says: "Keep on with this for the season and you will never have mildew." Other fungicides that are recommended as being effective are Jeyes' Cyllin soft soap, potassium sulphide (using ½oz. to a gallon of water, and adding the white of an egg to make the liquid more adhesive), and sulphuric acid. The proportions of the last-named I do not intend telling you, as I believe it to be a dangerous mixture to prepare, and requires great caution in application or the cure may be worse than the disease, and you will burn all the foliage off.

Black spot, another disease which attacks the foliage, is a far too frequent pest amongst our roses. It is easily detected by the large black circular spots which appear about midsummer. It is most unsightly, and causes the early falling off of the rose foliage. To prevent its recurrence spray with either of the fungicides I have mentioned, and collect and burn all leaves showing any sign of the fungus.

Rose rust appears in the summer on the foliage and wood in patches of orange spores, and in the autumn in small black points usually found covering the entire under surface of the leaves. These black points will remain on the fallen leaves during the winter, and in the spring will start into fresh growth infecting the young leaves with the orange fungus I have just described. To prevent it appearing another season all infested leaves must be collected and burnt, and the plants sprayed in early spring with potassium sulphide, using ½oz. to a gallon of water.

We all know only too well the aphis or green-fly which reproduce themselves in such an extraordinarily rapid manner that one day our roses seem clean and the next the young growth is smothered with this pest. Fortunately a good insecticide, such as Abol, or soft soap and quassia, will keep them in check, or better still, perhaps, your finger and thumb will do the work equally well. A more troublesome insect is the rose slug-worm, which devours the tissues of the rose foliage and causes disfigurement and injury to the plants. Spraying with hellebore powder will kill the pest and in the winter the surface soil beneath the attacked plants should be removed and replaced with fresh, for the slugworms, when fully grown, fall to the ground and pupate in the soil in their cocoons. Another insect pest is the leaf-rolling sawfly. Growers who love their roses will be on the lookout for them, especially in the early part of the season, and wherever they detect a curled-up leaf will pick it off and crush the occupant, the best and only cure for many of the insect pests.

Rose Gloire de Chedane Guinoisseau.—This hybrid perpetual rose was raised and introduced by Guinoisseau and Chedane in 1908, and stands quite at the head of this section, though it is only during the last two seasons that its merits have been widely recognised. I look upon it as one of the most satisfactory roses in the garden. It is not so vigorous in growth as some, but it carries good foliage.—E. M.

TRIAL OF DECORATIVE GARDEN DAHLIAS AT DUFFRYN.

(Concluded from page 949.)

The following varieties of dahlias were chosen at the Duffryn Trials as most worthy of notice for garden decoration:

Cactus Varieties.

Amos Perry (R. Cory).—Velvety-crimson, very free-flowering, 3ft.

Arthur Pickard (Dobbie).—Pale pinkish-salmon, fine habit, 5ft.

Bridal Crown (Mortimer).—Yellow shaded pink, 4 feet.

Conquest (Campbell). — Deep crimson-maroon, very erect, 4ft.

Duchess of Marlborough (Cheal).—Delicate silvery-pink, fine habit, 4ft.

Edith Carter (Shoesmith).—Yellow, heavily suffused rosy carmine; 4ft.

Effective (Hobbies). — Amber with rose centre, 4ft.

Floradora (Hobbies).—Rich crimson, long wiry stems, 3ft.

Glow (Hobbies). — Yellow, tipped apricot, 3ft.

Hon. Mrs. Greville (Cheal).—Orange-yellow, suffused salmon, 4½ft.

Jeanne Hardy (Cayeux and Le Clerc).

Mabel Needs (Mortimer).—Orange-scarlet, shaded plum, 3½ft.

Mrs. J. Barker (Mortimer).—Salmon-pink, 2½ft.

Mrs. J. S. Brunton (Mortimer).—Deep yellow, 4ft.

Mrs. D. Fleming (Stredwick).—Fine white, 3½ft.

Mrs. Chas. Foster (Cheal).—Rich rose-pink, 3½ft.

Mrs. J. Goddard (Cheal).—Glowing crimson, 3½ft.

Mrs. Landale (Cheal).—Yellow, suffused and edged bright rose, 4ft.

Mrs. Macmillan (Dicksons).—Centre white, deepening to mauve, 4ft.

Mrs. F. Paton (Cheal).—Brilliant crimson-scarlet, 4ft.

Nimrod (Mortimer).—Bright pink, tinted lemon, 2½ft.

René Cayeux (Cayeux and Le Clerc).

Rev. M. Limon (Treseder).—Rich bronzy-yellow, 3ft.

Snowdon (Campbell).—Pure white, 5ft.

Sportsman (Shoesmith).—Fine scarlet, 5ft.

Stability (Stredwick).—Rose-pink, 3ft.

Star (Carter Page and Co).—Bright bronze-yellow, 4ft.

Sweet Briar (Stredwick and Carter Page).—Clear pink, 4ft.

Sweetheart (Dicksons).—Salmon-pink, 4ft.

Thos. Parkin (Hobbies).—Bright orange, 3ft.

Victory (Cheal).—Rich coral.

Vivid (T. S. Ware).—Orange-scarlet.

West Hall Scarlet (Mortimer).—Bright scarlet, 3ft.

W. H. Treseder (Treseder).—Pale yellow, shading to pink at ends of petals.

Pompom Cactus Varieties.

Coronation (Carter Page and Dobbie). — Glowing red, very free, 3ft.

Firefly (Cheal).—Brilliant scarlet, tipped yellow.

Gracie (Cory and Dicksons).—Yellow and amber, tipped white, 3ft.

Magenta Queen (Dickson and Robinson).—Deep magenta, 3ft.

Miss Hicks (Dickson and Robinson).—Rich crimson, 3ft.

Selma (Cheal).—Rich rosy purple, 3ft.

Single Varieties.

Brilliant (Cheal).—Rich crimson-scarlet, yellow zone, 4ft.

Cardinal (Cheal).—Rich cardinal red, yellow disc, 3½ft.

Circe (Cayeux and Le Clerc).—Centre of petals white, broadly margined pink, 2ft.

Crimson King (Dicksons).—Rich crimson, 3ft.

Elsie (Cheal).—Purplish-crimson, edged white, 3½ft.

Fuji San (Dobbie).—Rich orange-yellow, crimson zone, 3½ft.

Kitty (Cheal). — Rosy mauve, chocolate disc, 3ft.

Little Othello (Cory).—Crimson, black centre, with ring of prominent yellow stamens, 2ft.

Mary (Dickson and Robinson).—Salmon with crimson ring, 2ft.

Mikado (Dicksons).—Scarlet centre, heavily margined clear yellow, 3ft.

Mrs. W. Hood (Dobbie).—Pure yellow, 3ft.

Onida (Dicksons).—Orange-salmon, shaded rose-pink, 3ft.

Owen Thomas (Cheal).—Crimson-scarlet, heavily tipped golden-yellow, 4ft.

Rosy Gem (Dickson and Robinson).—Pure rose with crimson ring, 3ft.

Rosemary Bride (Cheal).—Deep rich rose, lighter shade on margin, 3ft.

Union Jack (Turner).—White striped scarlet, 2ft.

Winona (Cheal).—Deep maroon, 3ft.

Bedding Varieties.

Barlow's Bedder (T. S. Ware). — Glowing orange-scarlet, 2½ft.

Cloth of Gold (Turner). — Clear yellow, show type.

Gluchaut (Dobbie and Carter Page). — Bright orange-scarlet, 2½ft.

Rising Sun (Cory).—Double scarlet, show form, 2ft.

Zwergsonne (Dobbie and Carter Page). — Canary-yellow, cactus-shaped flowers, 1½ft.

Pompom Varieties.

Ace of Diamonds (Keynes).—Bright scarlet-crimson, 3ft.

Annie Holton (Cheal). — Rich crimson, tipped silver, 3ft.

Bacchus (Cory).—Crimson-scarlet, 3ft.

Beauty (Dickson and Robinson).—Terra-cotta, shading to orange at base, 2½ft.

Blush Gem (Cory).—Mauve-pink, light centre, 3ft.

Bonella (Cory).—Deep rosy pink, shaded rose, 2½ft.

Crimson Beauty (Cory).—Bright crimson, 3ft.

Crusoe (Cheal).—Blush, edged rose-pink, 4ft.

Daisy (Dobbie).—Amber, shaded salmon, 3ft.

Darkest of All (Cory).—Blackish maroon, 3ft.

Dewdrop (Cory). — White with lavender edges, 3ft.

Douglas (Turner).—Deep maroon, shaded crimson, 3ft.

Emily Hopper (Dobbie).—Clear yellow, 3ft.

Evelyn (Cory).—Bright crimson, 1½ft.

Firebrand (Dickson and Robinson).—Bright flame-colour, 2ft.

Glow (Dobbie).—Rich coral, 3ft.

Ideal (Cory).—Pure yellow, 3ft.

Irene (Cheal).—Pale rosy mauve, 3ft.

Mars (Turner).—Bright scarlet, 3ft.

Neatness (Cory).—Pale amber, 3ft.

Queen of Hearts (Dobbie).—Pure white, 3ft.

Rodney (Dobbie).—Fawn, shaded yellow, 3ft.

Tommy Keith (Cory).—Red, tipped white, 2½ft.

Virginia (Turner).—Pure white, 3ft.

White Aster (Dobbie).—Pure white, quilled florets, 3ft.

Pæony-flowered Varieties.

Alecto (Turner).—Yellow, suffused crimson.

Balak (West).—Bright rosy crimson, 5ft.

Burne Jones (Dobbie). — Fawn, suffused rose, 3½ft.

Codsall Gem (Dobbie).—Deep yellow, 4ft.

Dormouse (West).—Velvety crimson, 3ft.

Elfrida (Hobbies).—Pink, shaded white, 4ft.

Frau Anna Galster (Dobbie).—Amber yellow, tinted red, 2½ft.

Hall Caine (Carter Page).—Yellow, with chestnut shadings, 4ft.

Hebe (West).—Pearly mauve, 2½ft.

Hermosa (Turner).—Shading from medium to pale mauve, 5ft.

H. J. Lovinck (Hobbies).—White, shaded mauve, 4ft.

Holman Hunt (Cory).—Rich dark crimson, 5ft.

John Green (Stredwick). — Yellow, edged bright red, 4ft.

Kakadee (Dobbie).—Lemon-yellow, passing to white at tips, 2ft.

Katherine (Hobbies). — Yellow, shaded brick red.

Kevington (Cannell). — Salmon, shaded fawn.

Kimberley (Cory).—Rosy carmine, yellow centre.

King Leopold (Cory).—Pale yellow, 5ft.

Ladysmith (Cory).—Violet-rose, 3½ft.

Lemberg (Turner).—Red with yellow base.

Liberty (Baker's).—Salmon-scarlet, 4ft.

London (Hobbies).—Crimson-scarlet, 4ft.

Lord Milner (West).—Yellow, edged white, 4ft.

Mafeking (Cory).—Fawn, suffused rose, 3ft.

May Day (Hobbies).—Yellow, shaded pink, 4ft.

Miss Dora Wilson (Cannell). — Rosy vermilion shadings on yellow ground, 4ft.

Miss Watson (Cory). — Creamy-white, striped and heavily marked rose, 3ft.

Mrs. J. Chamberlain (Cory).—Salmon, yellow at base, 4ft.

Mrs. Kerr (Cory). — Pale pink, suffused rose, 4ft.

Mrs. T. G. Baker (Cory).—Pure white, 4ft.

Nymphæ (Turner). — White with yellow base, 3ft.

Pantaloon (Cheal).—Deep crimson, tipped white, 4ft.

Paul Kruger (Cory).—Rose and white, 3ft.

Phidias (West).—Lovely shade of bright salmon-pink, 4ft.

Porcupine (Hobbies).—White and rose, 4ft.

Primrose Queen (Dobbie).—Clear yellow, 3½ft.

Princess Ida (Turner).—White, yellow centre, 4½ft.

Queen Mary (T. S. Ware).—Pure white.

Reynolds (West).—Deep crimson, 4ft.

Rubens (Dobbie).—Rose-pink, 4ft.

Salome (Turner).—Bright orange, shaded buff, 3ft.

Sheila (Turner).—Bright pink.

Sunset (Cory).—Vermilion, 4ft.

Sunstar (Carter Page). — Rosy-carmine, suffused yellow, 4ft.

The Geisha (Cory).—Yellow, suffused red, 4ft.

Titian (West).—Beautiful shade of rose-purple, 5ft.

Turner (Treseder and Dobbie). — Lovely pink, very large, 4ft.

Viscountess Newport (Cory).—Orange-red, shaded buff, 4ft.

Warrior (Cory).—Deep red, 4ft.

Mignon Varieties.

Agnes (Cheal).—Purple, distinct, 18 inches.

Daphne (Cheal).—Maroon, good habit, 18 inches.

Lancer (Cheal).—Scarlet, bushy habit, 18 inches.

Olive (Cheal). — Orange, very free, 18 inches.

Parisian Singles.

Notre Dame (Riding).—White, broad picotee banding of amber, 2ft.

Paris (Riding). — White, broad picotee banding of scarlet, 2ft.

Collerette Varieties.

Cantick (Dobbie).—Pale yellow ground and tips, heavily marked rosy-red, collar pale yellow, 4ft.

Countess I. Hardegg (Dobbie). — Purple passing to rose, white collar, 3ft.

Countess Dugon (Riding).—White ground, splashed rosy-purple, white collar, 3ft.

Cumbrae (Dobbie). — Deep rose-pink, shaded purple, white collar, 3ft.

Diadem (Dobbie).—Rose, with white collar, 3ft.

Exposition de Lyon (Riding).—Beautiful rosy-red, 3ft.

Frogmore (Dobbie).—Vermilion with yellow collar, 3ft.

Gunfleet (Dobbie).—Ruby, golden tips, 3ft.

Henri Farman (Dobbie and Dickson's).—Bright vermilion, edged primrose, 3½ft.

Holyrood (Cory-.—Ruby-red, golden tips, 3½ft.

Lynas (Dobbie). — Orange-salmon, collar pale yellow.

Madame J. Buyssens (Dobbie).—Dark crimson, edged rosy-carmine, 3ft.

Maurice Rivoire (Cory). — Rosy-carmine, white collar.

Negro (Dobbie). — Dark maroon, collar white, 3½ft.

Prince de Venosa (Dobbie). — Crimson, shaded violet, white collar, 3½ft.

Prince of Orange (Dobbie). — Beautiful orange self, collar tipped yellow, 3ft.

Princess Louise (Dobbie).—Rich crimson, white collar.

Queen Bess (Dobbie).—Orange-scarlet, yellow collar, 4ft.

Regularity (Stredwick). — Purple, with white collar.

St. Abb's (Dobbie).—Crimson, petals tipped yellow, straw collar, 3ft.

Sunburgh (Dobbie). — Purplish-mauve, heavily suffused white, 3ft.

Tarbat Ness (Dobbie).—Deep wine-crimson, tipped white, collar, pale yellow, 4ft.

Tuscar (Dobbie). — Wine-crimson petals, tipped white, collar white, 3ft.

Decorative Varieties.

Brentwood Yellow (West).—Golden-yellow, 2ft.

Charming (Keynes).—Clear pink, flowers of medium size, 4ft.

Ch. Ducrot (Riding).—Vivid scarlet, long-pointed petals, erect stems, 3ft.

Délice (Dickson and Robinson). — Bright rose-pink, 4ft.

Harmony (Keynes).—Silvery-pink, satiny, 3ft.

Hon. R. Borden (Cannell).—Golden-yellow, shaded old gold, 4ft.

Jeanne Charmet (Cory). — Lilac-pink, shaded white, 3ft.

Kaiserin A. Victoria (Carter Page).—Pure white, 3ft.

Le Grand Manitou (Carter Page).—Lilac-rose, spotted bright purple, 3ft.

Loveliness (Cory).—Lovely shade of rose-pink, 3ft.

Madame M. Collet (Cayeux and Le Clerc).—Deep salmon, shading to yellow centre, large, 4ft.

Mammoth (Cayeux and Le Clerc).—Intense crimson-scarlet, flowers large, 5ft.

Mont Rose (Riding).—Deep rose, 3ft.

Sea-shell (Cory). — Shell-pink and amber, small flowered variety.

Souv. de G. Douzon (Cory).—Bright scarlet, immense flowers, 5ft. 3ft.

Show and Fancy Varieties.

David Johnson (Dicksons). — Salmon, shaded rose, 3ft.

Duchess (Dobbie).—Orange-scarlet, 3ft.

Edward Mawley (Turner).—Crimson, very erect, 3ft.

J. Bennett (Turner).—Yellow, tipped red, 3ft.

Mariner (Cory).—Lilac ground, splashed purple, 3ft.

Merlin (Turner).—Orange-scarlet, 3ft.

Mrs. Ormerod (Dobbie).—Rosy-peach, 3ft.

Peacock (Treseder).—Maroon, tipped white, 4ft.

Queen of the Belgians (Turner).—Cream, tinted pink, 4ft.

Sunbeam (Treseder).—Clear buff, 2½ft.

Figs.—In the colder districts these may need a little artificial covering in very severe weather, but in the more favourable parts they seem to take harm in the majority of seasons. I have covered them lightly with bracken fronds with good results, and also taken the main branches from the walls, tied them together, and covered them with a little straw or mats. Figs succeed best in a firm root run; the drainage should be perfect, the soil good, sweet, with plenty of old mortar added, and all rammed tightly. H. MARKHAM, Wrotham Park Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

United Horticultural Benefit and Provident Society.

The monthly meeting of this society was held at the Royal Horticultural Hall on Monday, December 8, Mr. Arthur Bedford presiding. Five new members were elected, and four members were allowed to withdraw from their deposit account sums amounting to £15. The sick pay for the month on the Ordinary side amounted to £60 14s. 6d., and on the State section £23 3s. 8d., and maternity benefits were £9 for the month. A report on the chronic sick members was given by the secretary, which proved interesting reading; one member had been on the funds for nineteen years; the amount of sick pay he has received is £268 3s., and he still has £81 17s. 4d. on deposit; other chronic sick members have received the following amounts in sick pay: £213 16s., £167 18s., £145 18s., £108, £72 5s., £56 8s., £37 18s., and £28 10s.; while one member, who only joined the society some six years ago, has had upwards of £70; all of which shows the stability of the society, and suggests that all gardeners should join the United.

East Anglian Horticultural Club.

The annual meeting of this club was held on the 11th inst. at the Boar's Head Hotel, Norwich. In a very lengthy annual report presented by Mr. W. L. Wallis, the secretary, it was stated that the progress of the club during the year has been marked by activity through the whole of the programme of work adopted at the previous annual meeting. The attendance has been well maintained, upwards of 100 members coming to each meeting. The membership again shows a steady increase, and now stands at 377, making this one of, if not the, largest club or association of its kind in the kingdom. The club's finances show a balance in hand of £126 4s. 11d. There has been rather a heavier tax than usual upon the finances owing to several benevolent grants, but no one begrudged helping a distressed member. The monthly exhibitions have been an outstanding feature, the exhibits being of great educational value to the members. Lectures and essays have been a great feature, and evoked animated discussions. Reference was made to the excursion in the summer to Cambridge Botanic Gardens. Mr. John Willis was thanked for his meteorological notes, the Press for their kindness in giving notices of the meetings, and the officers for their services.

The report and the auditor's report were both well received and adopted.

In the election of officers for 1914, Mr. John Clayton was made president; Mr. T. Notley, Catton Hall Gardens, was elected acting vice-president; Mr. Chas. Daniels, treasurer; and the popular secretary, Mr. W. L. Wallis, was re-elected with acclamation. The members elected to serve on the committee in place of those who retire by rotation were as follows: Mr. J. W. Chapman, Ashwelthorpe Hall Gardens; Mr. E. F. Greene, Catton Grange Gardens; Mr. D. Howlett, Thorpe; Mr. Geo. Moore, Hethersett Hall Gardens; Mr. W. Shoesmith, gardener to F. W. Harmer, Esq., Cringleford; Mr. E. H. Starling, Honingham Hall Gardens; and Mr. J. D. Cockerell, gardener to G. E. White, Esq., Eaton.

Alterations in the exhibition schedule were next considered, and a formidable list of special prizes read out by the secretary. This gentleman also presented a strong list of lectures and papers for the coming year from well-known authorities. The matter of a

summer excursion to Kew Gardens was next debated, and it was unanimously agreed that, if at all possible, the club should arrange such an excursion for the summer. The secretary stated further particulars of this would be posted to the members in due course.

Mr. Willis's report of the weather pointed out how vegetation advanced during the mild spell of November, and some things were as forward as one usually finds them in March.

The exhibition tables carried flowers, fruits, and vegetables. Mr. W. Shoesmith had some fine grapes, and a well-flowered cypripedium; Mr. Cockerell had also a good cypripedium and the best plant of Begonia Gloire de Lorraine. A fine feature was the bunch of cypripedium blooms brought up by Mr. J. W. Chapman, Ashwelthorpe Hall Gardens, one of which was a distinct freak, having two lips or slippers upon the one stem.

Dundee Chrysanthemum Society.

The annual general meeting was held, under the presidency of Mr. W. S. Melville, in Lamb's Hotel on the 12th inst. Mr. W. F. Hill, in submitting his annual report, showed a credit balance on the year's workings of £10 1s. 5d. In moving the adoption of the reports, the President said it was so far satisfactory, but they could not hide the fact that their credit balance had been obtained by the practice of great economy on the part of the committee. The people of Dundee appeared to require something more than flowers to attract them. The one aim and object of the society had always been the cultivation of the chrysanthemum, and in that respect alone it had been very successful. Mr. William Grant said it was a disgrace that their beautiful show was not better patronised. It was a revelation in cultivation, and he questioned whether the display of chrysanthemums in six-inch pots could be excelled at any other show in Britain.

Retiring office-bearers were re-elected, and the names of Messrs. David Dickie, F. L. McGrady, D. C. Hutcheson, Alexander Mackay, and Thomas Maitland added to the list of vice-presidents.

Messrs. James Bethel and James Staward were elected to serve on the committee, and Mr. James Beats was re-elected.

It was agreed to hold the next chrysanthemum show on November 27 and 28, 1914, and various suggestions were made as to procedure.

Chester Paxton Society.

The twenty-sixth annual general meeting was held in the Grosvenor Museum on Saturday, when the chair was occupied by Mr. N. F. Barnes, Eaton Gardens. Mr. G. P. Milne, Hon. Secretary and Treasurer, in presenting the annual report, pointed out that there had been an increase in the list of members and subscribers during the past year, the figures now standing at over 600. The fruit and chrysanthemum exhibition held in November was, he said, one of the most successful held under the auspices of the society, the whole of the classes being more fully represented than on any previous occasion. The course of winter lectures had also been well attended, and the financial statement showed a credit balance in the bank of over £50.

The popular president of the society, Mr. T. Gibbons Frost, J.P., was re-elected, and Colonel Wilford N. Lloyd, M.V.O., J.P., Major MacGillycuddy, J.P., Mr. E. Peter Jones, J.P., and Mr. Edward Porritt were re-elected vice-presideuts. Mr. A. W. Armstrong (Messrs. McHattie and Co.) was re-elected chairman of committee, and the duties of consulting entomologist, and hon. secretary and treasurer, were respectively undertaken by Professor R. Newstead, J.P., and Mr. G. P. Milne, J.P.; while the following were elected to serve on the Executive Committee: Messrs. N. F. Barnes, J. Clack, W. Dodd, O. Edwards, W. Evans, J. Fleet, T. Gilbert, W. H. Little, S. May, E. Palin, G. H. Plant, J. Ryder, W. Seddon, E. Stubbs, R. Wakefield, A. Walker, J. Weaver, and J. Wynne.

Dumfries and Galloway Gardeners' Association.

There was a very large attendance at the last monthly meeting of the Dumfries and Galloway Gardeners' Association, which was held in the Wesley Hall, Dumfries, on December 6. Mr. S. Arnott occupied the chair, and introduced the lecturer of the evening, Mr. A. Cameron, The Gardens, Balgray, Lockerbie. He stated that the subject was the "Deciduous Calanthe," and remarked upon the magnificent spikes exhibited by Mr. Cameron at a previous meeting which were evidence that the lecturer was thoroughly well qualified to discuss the subject.

Mr. Cameron gave an able and practical description of the methods he followed in the cultivation of the calanthe, describing the treatment he adopted from the removal of old soil until the flowering stage, with full particulars of the compost, potting, top-dressing, temperature, etc., together with the names of what he considered the best varieties. The lecture was illustrated by a plant of C. Veitchi, carrying some splendid spikes of bloom. A short discussion ensued, and Mr. Cameron was heartily thanked for his paper.

As Mr. D. Hunter, the secretary and treasurer, wished that another gentleman should be appointed to undertake the duties, it was unanimously agreed to appoint Mr. W. Taylor, Brocklehirst Gardens, as honorary secretary and treasurer. Mr. Hunter was warmly thanked for his past services.

Bristol Gardeners' Association.

The fortnightly meeting of this association was held at St. John's Parish Rooms on Thursday, November 27, Mr. E. T. Parker presiding over a good attendance. The evening was set apart for an essay competition among under-gardeners, competitors being at liberty to choose their own subjects, but limited in the matter of time to fifteen minutes. Mr. Barrow was awarded first prize, and the subject was, "Gathering and Storing Fruit." Mr. Extence, with "border Carnations," came second; and Mr. Sweeting, with "Beds and Borders of the Pleasure Ground," was third; while Mr. Wright, with "Plant Life," was fourth. Each dealt with his subject in a very able manner, and all were highly complimented by the members present. Votes of thanks to the judges and to Mr. Parker concluded a very pleasant evening.

The prizes, kindly given by Mr. H. J. Smith (Messrs. Carter and Co., London), for two dishes of potatoes secured a keen competition, and were won by Messrs. Young, Neale, and Scott, in the order given. In the points competition, Mr. Jennings was awarded three points for a cypripedium, and Mr. Extence three for two dishes of potatoes. Two new members were elected.

Highcliffe Gardeners' Society.

The annual dinner was held on Monday, December 8, when a very pleasant evening was spent. The President, E. Huntley Hooper, Esq., was in the chair. After dinner the evening was devoted to song and speech, and the presentation of a silver medal and first-class certificates by the president to the various winners. A silver medal was offered to the member gaining the highest number of points at the various exhibitions and meetings during the year, and Mr. Weaver was the winner.

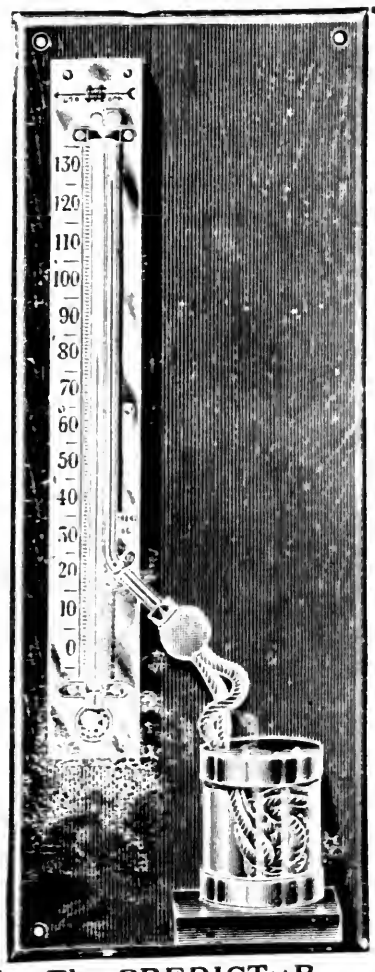
This society is a strong one, and well supported by gardeners and amateurs from a wide district in which great interest is taken in horticultural matters.

Lovely plants were placed on the tables by Mr. Weaver, of Chewton House; Mr. Skinner, of Highcliffe Castle; and Mr. Bell, of Amberwood. A single-stemmed spray of Chrysanthemum Mdm. R. Oberthur was exhibited by Mr. Weaver; it bore twenty-four blooms of good average size, and had not been disbudded.

Royal Scottish Arboricultural Society.

The annual meeting of the Aberdeen Branch was held in the Aberdeen University Buildings. Mr. Irvine, of Drum, presided, and after a number of new members had been admitted, Mr. G. D. Massie, the hon. secretary and treasurer, submitted the reports for the year now closing. The membership of the branch stands at 122; 16 new members having been admitted. The financial statement showed a balance in hand of £9 3s. 10d.

Mr. Irvine, of Drum, was re-appointed president. Professor Trail and Mr. J. Michie, Balmoral Castle; Mr. John Clark, Haddo House; and Mr. S. J. Gammell, of Drumtochty, were re-elected vice-presidents. Mr. Massie was re-appointed secretary and treasurer, and Mr. C. Stuart, forester, Durris, was elected to the committee in succession to Mr. Dawson.



The PREDICTOR.

AT A GLANCE

SIR HENRY CUNYNGHAME'S

FROST PREDICTOR

(PATENTED)

will tell you if the temperature of the air will fall below the freezing point.

No figures to consult nor levers to adjust. A glance at two thermometer tubes, arranged side by side, is all that is necessary. The **Predictor** also provides a very accurate thermometer, suitable for outdoor use.

OF SPECIAL INTEREST

to GARDENERS, FRUIT GROWERS, AGRICULTURISTS, HUNTSMEN, SPORTSMEN, and various Industries.

THE SALE OF LOW QUALITY MANURES.

The Board of Agriculture has issued a leaflet in which they state that their attention has been drawn to the sales as manures in different parts of the country of substances which are practically worthless as fertilisers, and to the sale of manures of low quality, which are offered at prices far above their real value.

It is stated in the leaflet that the vendors generally give in their advertisements and invoices a correct analysis of the constituents, and appear to expect that lack of knowledge on the part of the purchasers will prevent them from appreciating the true value of the substance as indicated by the analysis.

For instance, a manure (1) offered at £3 10s. per ton, and described as "a complete fertiliser in the cheapest form," is stated to contain the following constituents: Nitrogen, 1.23 per cent.; soluble phosphates, 5.0 per cent.; insoluble phosphates, 1.50 per cent. Three other manures offered at the same price contained respectively, according to the invoices, the following constituents: (2) Nitrogen, 1.15 (equal to ammonia 1.40), and phosphates, 7.0; (3) nitrogen equal to ammonia, 1.40, and phosphates, 8.0; (4) nitrogen, 1.0 to 1.25, and phosphates, 6.0 to 7.0.

It may be pointed out that on the basis of the unit values current at about the time the manures referred to were brought to the notice of the Board the quantities of nitrogen and phosphates contained in them could have been purchased in nitrate of soda, superphosphate of lime, and basic slag, at the following cost respectively:

(1) Nitrogen 1.3 ... ... = 14/3 Sol. phosphates 5.0 ... = 10/0 Insol. phosphates 1.50 = 1/9	= 26/0	
(2) Nitrogen 1.15 ... ... = 13/4 Phosphates 7.0 ... ... = 8/2	= 21/6	
(3) Nitrogen = Ammonia 1.40 = 13/4 Phosphates 8.0 ... ... = 9/4	= 22/8	
(4) Nitrogen 1 to 1.25 = 11/7 to 14/6 Phosphates 6 to 7 = 7/- ,, 8/2	= 18/7 to 22/8	

The manures would only be worth these prices if manufactured of first-rate materials like nitrate of soda, superphosphate and basic slag. Nitrogen may, however, be purchased in cheap forms in organic substances, while insoluble phosphates can be purchased in the form of ground rock phosphates at little more than half the sum they cost in basic slag. Assuming the nitrogen to have been derived from a low-grade shoddy and the phosphates from rock phosphates, the manures could have been compounded at the following cost respectively:

(1) Nitrogen 1.23 ... ... = 7/4 Sol. phosphates 5.0 ... = 10/0 Insol. phosphates 1.50 = 1/1	= 18/5
(2) Nitrogen 1.15 ... ... = 6/11 Phosphates 7.0 ... ... = 5/3	= 12/2
(3) Nitrogen = Amonia 1.40 = 6/11 Phosphates 8.0 ... ... = 6/0	= 1 /11
(4) Nitrogen 1 to 1.25 = 6/- to 7/6 Phosphates 6 to 7 = 4/6 ,, 5/3	= 10/6 to 12/9

These figures, it will be seen, vary from 10s. 6d. to 18s. 6d. It would indeed be possible to indicate even cheaper materials than those mentioned above, from which "manures" having the composition of (2), (3), and (4) might be prepared, materials which it would not pay the farmer to apply if he got them for nothing!

The loss to the cultivator, however, does not lie merely in the fact that he pays £3 10s. for something which at most is only worth 19s. to 26s., and may be worth no more than 10s. 6d. to 18s. 5d. A much more serious loss arises from the fact that the fertilising value of the manure is so low that it may be quite ineffective for the purpose in view.

Buyers should not be misled by suggestions that these compound manures have a value which is not indicated by the analysis. For example, it is frequently claimed by the sellers of such manures that the nitrogen they contain is of "animal origin" or "derived from organic matter," and on that account possesses some superior manurial value. Assertions are also frequently made as to the "large proportion of ammonia" they contain, though it is evident from the analysis given that the content of ammonia is really very low.

Apart from lime, which may be purchased at from 10s. to 18s. per ton in most localities, there are three constituents, and only three, which should be taken into consideration in arriving at the value of artificial manures, viz., nitrogen, phosphates, and potash. These are the constituents which an artificial manure is intended to supply to the crop, and any statements as to its value in other directions should be ignored.

OBITUARY.

SIR TREVOR LAWRENCE, BART.

It is with great regret we learn, just as we go to press, of the death of Sir Trevor Lawrence, Bart., of Burford Lodge, Dorking, on Tuesday, December 23. Sir James John Trevor Lawrence, Bart., was president of the Royal Horticultural Society for about thirty years, and only recently resigned his position on account of advancing years; he would have celebrated his eighty-second birthday next week. In the old John Company days he was in the Indian Medical service, but all through his life he was a keen gardener and botanist. In this latter respect he took after his mother, who had a famous garden and fine collections of plants at Ealing Park; while in the matter of medicine he took after his father, who was a famous surgeon in early Victorian times. For seventeen years he was Member of Parliament for Mid-Surrey, and sat on the Conservative side of the House.

Sir Trevor had a peculiarly intimate knowledge of orchids, and possessed one of the finest collections of these plants in the United Kingdom, comprising, it is said, not fewer than 3,000 species, varieties, and hybrids. Although the Burford Lodge collection is rich in fine varieties and hybrids, and includes the wonderful and rare Cypripedium Stonei platytænium, for which Sir Trevor paid an enormous price years ago, it was in rare species and orchids of botanical interest that he took the greatest pleasure, and he was always ready to purchase anything quite new. But orchids alone did not satisfy his horticultural tastes, and so Sir Trevor gathered together at Burford Lodge a beautiful series of the rarest flowering trees and shrubs. With these, as with orchids, he was especially successful, and many hundreds of awards from the Royal Horticultural Society must have been made to him for shrubs, orchids, and other plants.

Sir Trevor showed his interest in horticultural education by providing scholarships at Wisley, and in this and many other ways he advanced the art and science of which he was a master. The Lawrence Medal, instituted some years ago by the Royal Horticultural Society, will help to keep his memory green, and a fine portrait of Sir Trevor, in the Council Chamber at the Royal Horticultural Hall, Westminster, will show to succeeding generations what manner of man he was. His loss to horticulture and to botany is great; indeed, it will be a long time before horticulturists fully understand how much they owe to one who devoted the greater part of his long life to their interests, while the Fellows of the Royal Horticultural Society must never forget that he was one of the few who saved that now famous and wealthy body from an untimely end in the old, bad days at South Kensington.

MR. JOHN MATTOCK.

The well-known rosarian, Mr. John Mattock, of Headington, near Oxford, passed away on Monday, December 22, at the age of 76 years. He was a native of Bath, but moved to Headington about forty years ago, where he soon commenced business as a rosarian.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of THE GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Specimens of plants, flowers, and fruits for naming, or opinion, should be sent to the Editor of THE GARDENERS' MAGAZINE, 2, Adelaide Road, Brentford, Middlesex, and as early in the week as possible. All parcels must be sufficiently prepaid.

Secretaries of horticultural societies are invited to send early notifications of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in THE GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

LYCATE SKINNERI.—M. E. J., Derby: I have not been particularly successful in the cultivation of Lycaste Skinneri, and therefore beg that you will kindly tell me how to deal with this handsome orchid. I am an amateur with fairly good accommodation for orchids, and happy in the possession of cool, intermediate, and stove houses. I fancy I go wrong in my treatment of L. Skinneri during its resting period.—It is probable your plants have been over-watered during the resting season; they will grow best at the cool end of your intermediate house. Lycaste Skinneri should be watered liberally when growing, but when the growths are completed only sufficient water to keep the pseudo-bulbs in a plump condition should be given. A good potting compost consists of Osmunda fibre (or fibrous peat), sphagnum moss, and loam in equal parts; good drainage is essential. Lycastes should have as much light as possible at this time of the year, and ought to flower freely from now onward until the late spring.

CAMELLIA BUDS DROPPING.—S. E. S., Hertford: The flower buds have been dropping rather freely from my camellias, and I have no idea what is the cause. The house has been used for chrysanthemums and other flowering subjects. I shall be glad if you can help me.—Your camellia buds are dropping because there is too much atmospheric moisture in the house; we suggest that you keep the house drier, and admit plenty of air when the conditions out of doors will allow. No harm will occur to the camellias if you ventilate the house until the outside temperature falls to about 38 degrees.

HARDY HEATHS.—F. H. C., Warminster: Kindly give me the names of the principal hardy heaths, and state the colours of their flowers.—Among the heaths grown out of doors you will find Erica hybrida a robust grower, with long spikes of red flowers, which are about an inch in length; it makes a good display from December to May. E. arborea has white flowers. E. mediterranea, with its purple flowers, is very popular, and if a bed can be devoted to this species a fine effect

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

THE GARDENERS' MAGAZINE

ESTABLISHED 1833.

Leading Features of The "Gardeners' Magazine" of January 3rd, 1914, the first issue of the New Series, published at ONE PENNY.

THE HISTORY OF THE GARDENERS' MAGAZINE. A record of many years, bringing into focus the great events in horticulture during several reigns, and briefly indicating the part played in these matters by The GARDENERS' MAGAZINE.

CLIVEDEN GARDENS. An illustrated account of the beautiful gardens surrounding the stately Thames-side residence of Waldorf Astor, Esq., M.P., at Taplow.

THE LESSONS OF THE OLD YEAR. Showing how the many and varied experiences of 1913 may serve a very practical purpose in 1914.

THE NEW TREES AND SHRUBS OF 1913. An illustrated description of the more recent introductions from Western China and elsewhere.

BEGONIAS FOR WINTER FLOWERING. A practical article from the pen of a most successful grower, with illustrations of these useful and beautiful plants as grouped in the conservatory.

THE NEW ORCHIDS OF 1913. An illustrated review of the wonderful activity of hybridists and expert cultivators.

THREE WONDERFUL PALMS. Dealing with some extraordinary members of the valuable Palm family, and conjuring up scenes in the delightful island of Ceylon.

A PAGE FOR YOUNG MEN. In which "Note-taking," and the best methods of securing the fullest possible advantage of the notes taken, will be discussed for the benefit of the junior members of the profession.

PLANNING A WILD GARDEN. This will prove a valuable article for all who love woodland planting and the creation of beautiful natural scenery; illustrations will add to its practical value.

FRAGRANT ROSES. A subject very much before the public at present, and one attracting the closest attention of raisers and growers.

PRUNING FRUIT TREES. Another of those practical articles for which The GARDENERS' MAGAZINE is famous, and one of vital importance to all interested in the successful cultivation of Fruit.

KALES FOR WINTER USE. This will serve to remind readers of the great value of a homely vegetable, and direct attention to its range of variation.

TABLE DECORATIONS AT EXHIBITIONS. Numerous experts will contribute their experiences and opinions in connection with this peculiarly fascinating form of competition.

SOIL STERILISATION. No subject is of greater moment than Soil Sterilisation, and a well-known grower, who has conducted important experiments, will place the results before our readers.

SINGLE CHRYSANTHEMUMS. Single Chrysanthemums have, rightfully, sprung into popularity, and on this subject our readers will have the advice of one of the leading cultivators of the present day.

The Leading Contributors to this issue will be :—

Mr. JAS. HUDSON, V.M.H.
Mr. E. MOLYNEUX, V.M.H.
Mr. S. ARNOTT, J.P.
Mr. HUGH MACMILLAN.
Mr. J. GARDNER.
Mr. GEORGE GORDON, V.M.H.
Mr. W. HALES, A.L.S.
Mr. A BULLOCK.
Mr. PERCY CRAGG.
Mr. J. C. NEWSHAM, F.L.S.

Offices: 148 & 149, ALDERSGATE STREET, LONDON.

will be produced in winter and early spring; and it is also very useful for planting at the edge of a border. E. tetralix, with pale red flowers, is very common in some parts of Surrey. E. cinera, with purple flowers, which change to blue as they fade, may be used with good effect on a sunny rockery. Erica carnea with pale purple flowers, and E. vagans (the Cornish Heath), with pale purplish-red flowers, is also to be recommended, while E. carnea, flesh coloured; E. coronodes or lusitanica), pale pink; E. Veitchi, white; and E. vagans, white or red, are other good kinds.

BOOKS ON BOTANY AND CHEMISTRY.—F. E. F., Wymondham: I shall be much obliged if you will be good enough to give me a short list of books dealing with botany and chemistry. These books should be suitable for study by anyone entering for such an examination as is set by the Royal Horticultural Society.—Excellent books suitable for your purpose may be chosen from the following: "Agricultural Botany," by John Percival, F.L.S., 7s. 6d.; "Elementary Botany," by J. W. Oliver, 2s.; "Primer of Botany," by Sir J. D. Hooker, 1s.; "Structural Botany (Flowering Plants)" by Dr. D. H. Scott, 3s. 6d.; "Introduction to Plant Ecology," by Prof. G. Henslow, M.A., V.M.H., 2s. 6d.; and "The Chemistry of the Garden," by H. H. Cousins, 1s.; the latter is a very comprehensive and inexpensive work for students.

EVERLASTING PEAS.—M. M., Wisbech: You will greatly oblige me by giving the names of those species of perennial Lathyrus which are of value in the garden, as I wish to make experiments with them, and so need a good collection to start with. The chief perennial species of lathyrus are: L. magellanicus, with purple flowers freely borne from June to September; L. heterophyllus, which flowers during the same period but is lacking in colour; L. palustris, a summer-flowering species, with blue and purple flowers; L. rotundifolius, with rose-coloured flowers, from May to July; L. sylvestris has rose-coloured flowers; and L. tuberosus, which is a naturalised perennial, and has rose-coloured flowers. We assume that you have L. latifolius, the ever-popular perennial species, and its varieties; if not, you must obtain these as they are among the finest plants in the genus.

GAZANIAS FOR THE FLOWER GARDEN.—G. F. H., Epsom: I believe gazanias were largely grown for summer bedding a few years ago, and so I thought of reviving their cultivation here. There are two or three old plants in pots in a greenhouse, but I do not care to deal with them until I know the best means of increasing stock. Perhaps you can help me.—The best method of propagating Gazanias for the flower garden is by taking cuttings of the side shoots, near the base of the plant, in August; these should be inserted in sandy soil in a close frame. When planted out in summer Gazanias prefer a sunny spot. You may be able to take a few cuttings from your plants in the spring, and they will grow freely if treated in the manner advised. G. ringens has been largely used as a bedding plant, and numerous garden varieties have been raised from it, including G. uniflora. The bright orange flowers of G. splendens produce a fine effect, and G. Pavonia is also a good plant.

ROOT-PRUNING APPLE TREES.—D. P., Hull: There are one or two bush apple trees here which have produced excessively strong growths, and I feel sure they would be improved if root-pruned. Would it be too late to deal with this matter now, or would you proceed at once? In the south I used to root-prune trees directly the leaves had fallen.—It is not too late to root-prune your apple trees, but the work should be proceeded with at once, and care must be taken, when cutting the strong roots through cleanly with a sharp tool, not to damage them unnecessarily, because when roots are bruised a disease may follow, and they will die back instead of emitting healthy young fibres from the portion where the cut was made.

CULTIVATION OF CYPRIPEDIUM INSIGNE.—J. H., Coggeshall: Please tell me how Cypripedium insigne should be managed for flowering about Christmas time. My plants are not a success, and they will not be in bloom until the middle of January.—To produce flowers of Cypripedium insigne for the Christmas season, the plants should be given as much light as possible in November and December. The temperature should be about 54 degrees at night, and 58 degrees in the day, but should the temperature rise ten degrees higher during the day no harm will occur if the rise is obtained from sunheat. When repotting C. insigne, which should be done soon after the plants have flowered, afford a good compost of three parts loam, one part of Osmunda fibre, and one of sphagnum moss, with a good sprinkling of silver sand and broken crocks added. It is a good method to stand the plants on inverted pots in order to bring them nearer the light, and if this is done always the flowers will develop earlier than they otherwise would. Of course, as soon as the flower buds show well it is an easy matter to hasten flowering by the use of a little extra warmth.

ARAUCARIAS.—Mr. J. H., Monmouth: I only know two species of araucaria, viz., A. imbricata and A. excelsa, but I understand there are others grown in this country. Will you please give me the names of other species, and say whether these are hardy or not in our country?—There are a fair number of araucarias grown in this country, but few of them are hardy. A. imbricata is quite hardy, and is the one most generally grown. A. excelsa is very useful for a large greenhouse or conservatory, and there are several varieties of it; A. e. var. glauca, is one of the best, having lighter green and very glaucous foliage. A. Cunninghami is hardy on the south-west coast of England, as also is the variety glauca, which has handsome silvery leaves, and is a fine plant. A. Goldieana is good for greenhouse decoration, and A. Balansæ may be used for the same purpose. A. Rulei var. elegans, a comparatively dwarf kind, is a very graceful plant for the conservatory, as also is A. Bidwilli, of regular and symmetrical habit.

PROPAGATION OF ERANTHEMUM PULCHELLUM.—A. F., Chesterfield: I enclose a small flowering spike, taken from a plant now in full bloom. Kindly tell me the name of the plant, and how propagation is effected.—The plant is Eranthemum pulchellum, and cuttings may be inserted any time from March to June. Being a soft-wooded subjects, the cuttings will readily root in sandy soil if placed in a temperature of about 70 degrees. A bell-glass or a close frame is required for them, and when the cuttings have rooted they should be placed in 3-inch pots. The best compost for E. pulchellum consists of equal parts of leaf-mould, peat, and loam, with a little silver sand added. As the plants advance in size they should, of course, be potted again, and plenty of water be given them during warm weather when they are growing freely.

KEW HAND LISTS.—C. J. C., Orpington: Will you please tell me where I can obtain the Kew hand lists, what are the prices charged, and how many lists are issued?—The official Hand Lists on sale at the Royal Gardens, Kew, are as follows: Hand List of Trees and Shrubs (excluding Coniferæ), post free, 1s. 7d.; Coniferæ, post free, 4½d.; Trees and Shrubs, and Coniferæ, in one volume, post free, 1s. 11d.; Ferns and Fern Allies, post free, 6½d.; Herbaceous Plants, post free, 2s. 11d.; Orchids, post free, 1s. 2½d.; Tender Monocotyledons, post free, 11d.; Orchids and Tender Monocotyledons, in one volume, post free, 1s. 4½d.; Tender Dicotyledons, post free, 2s. 10d.

MEALY BUG ON VINES.—H. G., Paignton: Can you help me in my efforts to exterminate mealy bug on our vines? When I took charge the vines were in a very dirty state, and so I took up several new canes and cut out the old ones, but the pest remains. I have tried several insecticides, and made one by boiling 2lbs. of soft soap in a gallon of water, and adding one pint of paraffin; we washed the vines twice with this, and have paraffined the house and wires several times, but still the horrid pest is with us. I should be glad to hear of a good and safe remedy. Does methylated spirit kill mealy bug?—When vines are infested with mealy bug the pest is most difficult to eradicate. All loose bark must be removed, and the vines thoroughly washed with warm soapy water; no harm will occur if soft soap is rubbed on with a brush and then washed off, and when the vines have been cleaned they should be dressed with a good proprietary compound, used according to the directions given with it. It will be necessary to cleanse the vinery thoroughly, inside and out, and particular care must be taken with all crevices, glass laps, etc. If the woodwork can be painted after cleaning, and walls limewashed, so much the better.

COUGHS, COLDS,
ASTHMA, BRONCHITIS,
and all kindred ailments are speedily relieved by
Dr. J. Collis Browne's
Chlorodyne

The RELIABLE FAMILY MEDICINE
In DIARRHŒA and other bowel complaints, Dr. J. COLLIS BROWNE'S Chlorodyne acts like a charm; its soothing and restorative effects are equally marked in RHEUMATISM, GOUT, NEURALGIA, and it effectually cuts short all attacks of SPASMS, HYSTERIA, PALPITATION.
Convincing Medical Testimony with each bottle.
Of all Chemists, 1/1½, 2/9, 4/6.
Always ask for the ORIGINAL and ONLY GENUINE — Collis Browne's

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

T. N., Exeter.—Ruta graveolens.

R. E. S., Newport.—Coleus thyrsoideus.

W. E. K., Bangor.—Callicarpa purpurea.

D. O., Englefield Green.—Primula floribunda.

G. W., Birmingham.—1, Acacia Baileyana; 2, A. dealbata.

G. C. J., Roehampton.—1, Adiantum cuneatum; 2, A. c. gracillimum.

H. H., Caister.—1, Erica carnea; 2, Lasiandra macrantha; 3, Exacum affine.

R. S., Norwich.—1, Cymbidium grandiflorum; 2, Cypripedium Memoria-Moensi; 4, Epidendrum variegatum; 5, Vanda cœrulea, a poor form; 6, Lælia anceps, var. Barkeriana.

Moschosma riparia. — Although vast tracts of country have been opened up in Africa within recent years, we have not received therefrom many plants of value for our gardens. Among the few, however, are at least three good winter-flowering subjects, namely, Coleum thyrsoideus, with rich, cobalt-blue blossoms; Erlangea tomentosa, a Eupatorium-like plant with heads of lilac-tinted flowers; and the Moschosma above named. This belongs to the Labiate family, and the leaves have the odour common to many members of the order. The flowers, which are borne in erect branching panicles, are small, but collectively they form a pleasing feature. In colour they are whitish with purple anthers. M. riparia is an easily-grown plant, and is effective for some weeks at this season.—W. T.

CLAY'S FERTILIZER THE STANDARD PLANT FOOD

"THERE IS NOTHING LIKE CLAY'S TO BUCK THINGS UP."
The Fruit-Grower.

SOLD EVERYWHERE in **6d.** and **1/-** TINS; and in BRANDED and SEALED BAGS:—7 lbs., **2 6**; 14 lbs., **4 6**; 28 lbs., **7 6**; 56 lbs., **12 6**; 112 lbs., **20/-**.
Or direct from the Works, Carriage Paid in the United Kingdom for Cash with Order (except **6d.** TINS).

Every Genuine Bag, Tin and Seal bears this Trade Mark.

CLAY'S FERTILIZER LONDON TRADE MARK

Used at the Royal Gardens; throughout the grounds of the Royal International Horticultural Exhibition, 1912; by Government and Municipal Authorities, and by Horticulturists Universally.

Full Directions for Use are included in **"CLAY'S SUCCESSFUL GARDENING"** (Fifth Edition), Greatly Enlarged, and containing 332 pages of valuable information by over 30 well-known Gardening writers. Embellished with Coloured Plates and bound in Cloth. Price **1/-** net. Of Seedsmen, etc., or Post Free for that amount direct from the Publishers:

CLAY & SON, MANURE MANUFACTURERS AND BONE CRUSHERS, STRATFORD, LONDON, E.

CATALOGUES RECEIVED.

MISS HILDA HEMUS, UPTON-ON-SEVERN.—A catalogue "Mainly About Sweet Peas, Various Plants, and a New Society." Sweet peas occupy the major space.

E. WEBB and SONS, WORDSLEY, STOURBRIDGE.—As usual, the seed catalogue issued from Wordsley is a fine production, freely and splendidly illustrated, entertaining, and instructive. The firm offers a number of novelties in flowers and vegetables.

DOBBIE and CO., EDINBURGH.—Excelsior Pansies on the front cover and Collarette Dahlias on the back cover, all in colours, make this firm's 1914 catalogue very attractive. Between the covers there are 224 pages, packed with descriptive, instructive, and interesting matter, and containing many illustrations. Seeds and plants are listed, and cover a very wide range of subjects.
